However, we are now getting into "the Professor's own" vein—namely, the declamatory and vituperative, and will therefore desist from that strain, and give him a piece of sound advice; which is, that if he be really anxious for the interests of architecture, and not, as we strongly suspect, intent upon ingratiating himself with those he has gone over to, he would be more likely to promote better taste, were he to abandon wholesale indiscriminate reviling of the architects and buildings of the present age for temperate, or at least intelligible, criticism. If the Professor can do anything more than bark and howl at his architectural brethren, they will, no doubt, attend properly to advice properly given. But by persisting in the course he seems now bent upon, his rabid invectives will obtain for him nothing better than their universal dislike and derision; nor does any one feel it a reproach to be decried by him, since not the slightest merit is attributed to any of his neighbours. Undoubtedly, Welby Pugin has earned for himself some distinction, yet hardly is it of a very enviable kind, for he has made himself no better than a laughing-stock, and his name a by-word of reproach; with which remark we shall ourselves now say the word of good-by to the man of St. Marie's Grange, and the Professor of St. Mary's College.

SIR WALTER SCOTT'S MONUMENT.

Letter to his Grace the Duke of Hamilton, and the other Noblemen and Gentlemen, the Committee appointed by the Subscribers for a Monument in Edinburgh to the Memory of Sir Walter Scott. Edinburgh, 1838.

Mr. Cadell, one of the sub-committee, here enters his protest against anything in the Gothic style being adopted for the architectural part of the projected monument. This much we plainly understand, but can make out very little more; for although the letter may be intelligible enough to those to whom it is addressed, and who are, of course, acquainted with the whole of the proceedings referred to, we must confess it contains by no means so clear a statement of them as to enable those who, like ourselves, know no more of the matter than what they are told, to comprehend it very clearly. It would not have been amiss, therefore, since the writer determined upon publishing his letter, had he prefaced it by a plain narrative of the proceedings up to the time of its being written—viz., March 15.

What we can collect from the letter itself is, that Mr. Kemp's design, which obtained one of the fifty-guinea premiums, has at present many in its favour, while Mr. Cadell is decidedly averse to it. He speaks of it contemptuously enough, as emanating from one "unheard of as *professional*, and who can adduce no specimen of what he has done in architecture, not even the erection of a cowhouse!" This, it strikes us, is very illiberal prejudice, to say the least of it, and abets a system calculated to keep talent back, instead of encouraging it. If Mr. Kemp was never heard of before, it is so much the more to his credit that he should, all at once, have distinguished himself by producing a design that obtained one of the premiums, and that has been allowed by Mr. Burn, himself well known as an eminent Scottish architect, to have been "*the best he* had seen" of the proposed monuments. The question, we presume, is not whether Mr. Kemp has ever built a "cowhouse," but whether his design was worthy of being carried into execution; for, if not, it ought not to be so, although he had built not only all the "cowhouses," but all the houses in Edinburgh itself. Whether James Wyatt ever tried his hand at first building a stable we know not, yet the Pantheon, in Oxford Street, is generally considered to have been his architectural *debut*, although he was, till then, quite "unheard of as *professional*." Really we must say that we dissent *toto cœlo* from Mr. Cadell, in regard to the argument he there goes upon; for we hold it to be an exceedingly ungenerous one, and one, moreover, which almost betrays that he trusts more to the prejudice likely so to be excited against Mr. Kemp, than to any valid objections he (the writer of the letter) can bring forward against the design; since, if he could prove it to be unsatisfactory as a design, wherefore should he attempt to raise objections against it on any other grounds?

It seems, besides, to us, that the course of argument adopted by Mr. Cadell is altogether at variance with the system of competition, one main advantage of which is, that the names of the competitors being concealed, the judges are likely to decide impartially, if not always discreetly, and to award the prizes according to the degree of merit they discern, although by so doing they may stumble upon one "unheard of as professional." So far we speak our own sentiments quite impartially; for we do not pledge ourselves to promise that we should stand up strenuously for Mr. Kemp's design, had we the opportunity of examining it. At present we can only say, that Mr. Burn's testimony in its favour weighs quite as much with us as all that Mr. Cadell urges against it. Instead of fully describing it, which he might have done in a note, if not in the letter itself, all that he enables us to understand of the design is, that it is a Gothic spire, about 138 feet high, below which would be four open arches (i. e. one arch on each side), within which would be placed the statue of Sir Walter. He contends, that anything like a steeple or spire, which can be considered only as adjunct to a church, would be an absurdity. Yet, if an absurdity, it must be admitted to be less preposterous than the frequent one of a column, with a statue hoisted upon it; because a spire is at least an integral structure, although applied only in combination with other parts, whereas a column is a mere COMPONENT MEMBER of an edifice, never intended to stand by itself. A spire, like a tower, is complete, though nothing be added to it; but not so a column, because the latter requires the entablature it is intended to support. Therefore the spire is, of the two, infinitely the less objectionable; and there is, besides, precedent for such form in our ancient Gothic crosses, as in that removed from Bristol, and now standing in the grounds at Stourhead. It is very possible that the design in question may be too much of a mere spire, which form may not be well modified to suit the particular purpose. This is a point on which we can offer no opinion; it is enough for us to show that the ground of objection taken up by Mr. C. is somewhat frivolous and untenable.

Yet, if he shows himself to be rather short-sighted in overlooking the analogous, and far more censurable case of a Grecian column being employed as an independent architectural object, it must be allowed he manifests extreme foresight and long-sightedness when he says, that a spire will be likely to be misunderstood even in our day, and far more so when we are gone. Now, without misunderstanding Mr. Cadell, it is difficult for us to understand how the kind of inconvenience he contemplates can arise. Probably he means no more than it will not be understood by those who may happen to see it, without having ever heard that such a thing existed; that is, it will not be understood by those who fall suddenly down from the clouds. Equally groundless is the apprehension that it will at all events be a puzzle and mystery to those who come after us. Does the writer, then, contemplate the chance of some strange pause or chasm in the series linking one generation to another, during which everything connected with the monument will have been utterly forgotten?

more likely than ever to be quite forgotten, when records of them are diffused through the press in innumerable ways? If so, future antiquaries will be terribly posed; and some of them, perhaps, will write very learned dissertations to prove that Athens was situated north of the Tweed, in confirmation of which hypothesis they will confidently appeal to the remains of the Parthenon on the Calton Hill. Alas! for poor posterity, how egregiously will it be hoaxed and mystified, not only in that, but numerous other instances.

We have reserved for this last place Mr. Cadell's objections to the adoption of the Gothic style, for at first they looked so formidable, that we almost thought our more prudent course would be to *shirk* them altogether. Yet, on looking at them again, we took heart, discovering them to be in fact perfectly harmless. Besides, ridiculing the "*gingerbread taste*" of monastic Gothic ornaments—even so, the gingerbread taste!—he cites no other than Sir Walter Scott himself as a witness on his side, quoting two passages from his works, which certainly do appear at first sight to discountenance all imitation of that style. Yet it is at first sight only, for as soon as we give ourselves time to think, we perceive that the argument is not propped, but *Mrs. Malaproped* by the quotation of those passages, which go no further than to show that Sir Walter had a horror—and no wonder, of such Gothicizing as that exhibited "in a cupboard in the form of a cathedral, and a pig-house with a front borrowed from the façade of an ancient chapel." Does the ridicule he cast upon such absurdities warrant us in concluding that he disliked or undervalued this style itself? Quite the contrary; it was his admiration of it that led him to deprecate trumpery and paltry imitations of it for unworthy purposes. That he was not at all averse even to modern imitations of it, when appropriate and upon a suitable scale, we have sufficient proof in one of his works, namely, his own mansion at Abbotsford, although it did not exactly suit Mr. Cadell's purpose to quote that. But we conclude, for our review on his pamphlet is growing nearly as long as the pamphlet itself.

We subjoin in this place two letters on the subject of the Monument (the first by Mr. Hamilton, the architect), which have appeared in the "Edinburgh Courant."

57, York Place, March 27, 1838.

Dear Sir,—I have received your letter of yesterday. I am aware of, and sincerely regret, the want of unanimity which has arisen regarding the proposed Monument to Sir Walter Scott. I early anticipated that difficulties would arise, and have always thought that in such cases some tribunal, chiefly professional, perhaps, but so constituted as to carry great weight with the public, would be the fittest to give a satisfactory decision upon competing designs.

Though I should willingly avoid any share in these disputed matters, I feel a deep interest in them as a citizen of Edinburgh, and an admirer of our immortal countryman, and therefore submit the following answers to the queries you have put to me:—

1. Mr. Kemp's design has little resemblance to the spire of Antwerp Cathedral, which is of a very light and graceful outline. The arrangement of some parts of his detail, however, approaches to that of Antwerp.

2. The statement that Mr. Kemp's design resembled the spire designed by me for John Knox's Church, was made by you, I believe, entirely on your own authority. For myself I never saw Mr. Kemp's plan till the middle of last week, when I recognised an accordance between some features of his design and of mine, not only in so far as regards the spire itself, but also in reference to the four small towers or buttresses, abutting diagonally against Mr. Kemp's monument at its base, and which are not dissimilar to those at the west end of John Knox's Church. Unquestionably, however, many deviations occur, but instead of offering my own opinion on this subject, I beg to send you a drawing of the John Knox steeple, made about eight years ago, to the base of which my son has attached a sketch of the west end of the church itself, omitting of course the tracery of the great window, and slightly varying the position of the two lateral towers, so as to make the arrangement somewhat similar to that adopted by Mr. Kemp.

This will afford the groundwork for a comparison, but it will be necessary to keep in mind that my spire was to have been 250 feet high, and that any such design for a spire about half the height would be very defective.

In regard to Melrose Abbey, I observe that Mr. Kemp states that "the whole of the details in his design are strictly copied from Melrose Abbey." The ornaments of the parapets, and some other details, undoubtedly resemble those of Melrose; but while the general design is of a character altogether different, a proportion of the details is without any precedent in that building. As examples of this, I may refer you to the four towers at the base, and the forms of the flying buttresses. There are other instances, but it is needless to be more particular.

In giving these instances I do not mean to disparage Mr. Kemp's design on that account, as I agree with Mr. Roberts in thinking that if appropriateness is observed, there is no necessity for selecting the enrichments from an

To your [illegible]

1. Your first question involves a matter simply of opinion, I may therefore freely state that I should regret to see Mr. Kemp's design followed out. To my mind it is deficient in the monumental character, which is here the primary requisite. If it is not to be regarded as entirely anomalous, it will most probably be considered as a highly decorated Gothic steeple, the appropriate adjunct only of a church, or perhaps a town-hall, and thus its leading character and effect can be but little modified by the statue introduced under the vault of the base. The design contains solecisms also which ought not to characterize a national building like this—for example, each of its four fronts present a pointed gable similar, no doubt, to those of Melrose; but in that and other buildings worth quoting as examples, the pointed gable invariably indicates the termination of a roof, and it is quite unappropriate to introduce such a feature where a pointed roof neither is nor ought to be.

2. Upon the subject of your second query, the committee have already obtained a professional opinion from a gentleman of the greatest eminence. I do not, therefore, feel warranted in entering upon it. Some of the preceding remarks are, as you may observe, somewhat different from those of Mr. Burn; but on an occasion such as this, I do not imagine that a full expression of opinion on matters of mere taste can give cause of displeasure to any one. I may be permitted to observe, however, that it does not appear that the committee have employed Mr. Burn to make a formal and detailed professional examination of this subject, which is much to be desired; it is an exceedingly complex one, and the object in view is to provide not merely an ordinary, or even a great degree of security, but the highest practicable solidity, so as to guarantee an indefinitely long endurance.

3 and 4. The best materials for building, both as regards beauty and durability, to be found in this quarter, is the Craigleith stone, and that, I humbly think, should be used in the erection of such a monument. The Binney stone is softer, and probably less solid; at all events, we have not sufficient experience of its durability, and this monument is not a subject for experiment.

I am sorry I cannot answer your inquiry as to the probable cost of the design, for neither has there been time for this, nor do the drawings which I have seen afford the means of ascertaining the point.

In conclusion, I trust the committee will do me the justice to believe that in thus freely, though rather hurriedly, and perhaps imperfectly expressing my sentiments, I am very far from presuming to impugn their taste, their judgment, or their motives, for all of which I have the sincerest respect.

Being called upon by you, as a member of the sub-committee, will, I hope, exempt me from the charge of intrusion; and having decided to answer your call, I have thought it best, as well as most respectful, to express my opinions without reserve.

I am, &c.,

To Robert Cadell, Esq., &c. &c. &c. THO. HAMILTON.

TO THE EDITOR OF THE COURANT.

Royal Exchange, 30th March, 1838.

Sir,—As I feel a strong desire to see the admirable design of Mr. Kemp for Scott's Monument erected, permit me, through the medium of your valuable paper, to offer a few hints respecting certain objections which have been made to it by some of the members of the committee at their meeting of Wednesday last. I refer especially to the remarks of Lord Meadowbank, which I shall endeavour to show are, in some instances, founded on a misapplication of the relative proportions of different buildings, and in others, in a misconception of the design. This is more especially necessary in justice to all parties, as any remarks from his lordship, so distinguished for his patronage of the fine arts, are calculated to carry great weight with the public.

Respecting the proportions of the building, "Lord Meadowbank reminded the meeting that the height of it was to be 138 feet, and the abutments of the base were precisely the same size as the abutments in Canterbury Cathedral, but the height of Canterbury Cathedral was 230 feet. One or other, then, must be out of proportion." The objection here seems to be, that the "abutments" (more properly the piers) of Scott's monument are too large.

Now, even admitting the accuracy, in every respect, of the statement, we have to remark, that the two buildings are totally different in character and arrangement. The "abutments" or piers of Canterbury Cathedral are under cover of the roof, and are surrounded by the piers of the nave and choir, and therefore partake of the same light character. What would be their effect were the roof and surrounding buildings removed, and the whole height of the tower, resting on the four slender piers, exposed to view? Now, Scott's Monument is in this condition, and the piers must necessarily, therefore, have a massive and solid effect in order to harmonize with the superstructure. And when his lordship states that the piers are precisely the same size as those of Canterbury, it must be admitted that they are substantial. Do they appear out of proportion to the superstructure? That has never been hinted at, and, therefore, a comparison with Canterbury, or any other building, is singularly misplaced.

Lord Meadowbank, in the course of his speech, states, "that the thickness of the walls up to the second and third floors was only one foot three inches, not half the thickness of an ordinary dwelling-house, and in the two tiers above, the thickness was only eight inches." "Such a structure," it is added, "would not stand one of our tempestuous winters." Now, with all due deference to the opinion of Lord Meadowbank, I would respectfully submit

[illegible] his lordship [illegible] of the design, for there is not a single part of the building that can with any propriety of language be called a "wall." It is composed of an assemblage of massive Gothic pillars, buttresses, pinnacles, and turrets, arranged in such a scientific manner as to call forth the high approbation of Mr. Burn, who "expressed his great admiration of the elegance of Mr. Kemp's design, its purity as a Gothic composition, and more particularly the constructive skill exhibited throughout, in the combination of the graceful features of that style of architecture in such a manner as to satisfy any professional man of its principles, and the perfect solidity which that structure would possess when built."* No doubt some of these massive turrets are pierced for the small spiral stair leading to the top of the tower, the outer casing of which must be the walls referred to by his lordship; but this does not weaken these turrets in the least. The opposite sides, which are formed of stones of one piece in thickness, are bonded together by the steps of the stair, and rendered, if any thing, more durable than if built solid. The slender piers of the magnificent bridge at the Dean were built hollow, and united by bond stones in this manner, purposely to render it more durable. And the only turret remaining of the magnificent Abbey of Arbroath is the one which contains the stair. The thickness of the casing of the spire of Glasgow Cathedral, the drawings of which now lie before me, is only about eight inches, and has endured for many centuries, and is now as stable as when built, and that although not united by bond stones or steps of any description.

Many of the smallest turrets of Melrose Abbey, the prototype of the monument, are as entire as that day they were erected, when the massive walls of the border towers have crumbled into ruins.

On the whole, the controversy on the merits of this design seems to be contracting within very narrow limits. It is stated by Lord Meadowbank himself that "he did not mean to enter the lists in point of taste with the hon. gentleman opposed to him." This appears to be an admission of the beauty of the design. The question of originality seems conceded, for it is added that "his lordship had the authority of Mr. Burn for stating, that there was no instance of towers being constructed with open arches on all sides."—"It might be good taste, but *it was a new taste*."

In a letter from Mr. Hamilton, in reply to some queries which Mr. Cadell had addressed to him, he states that "Mr. Kemp's design was a *little* resembling the *Tower of Antwerp*," and that "it was *something like*" Mr. Hamilton's plan for the spire of John Knox Church, itself confessedly a copy of Antwerp, "from drawings and measurements made on the spot."

The objection as to the obscurity of the architect seems also to be given up, for Lord Meadowbank finely remarked, that "he did not believe there was a man in the room who would not rather encourage the architect on that account."

Should the remarks now submitted tend in any measure to remove the objections of his lordship as to stability, the question would seem to be brought to a conclusion; and I earnestly hope that at the next meeting the committee may approve of the recommendation of the sub-committee, as beyond all controversy the mass of the subscribers are in favour of a combination of architecture and sculpture.

I am, &c.

D. C.

[A paragraph which has since appeared in the papers, informs us that Mr. Kemp's design for the monument is to be adopted, and that the statue is to be executed not by Sir F. Chantrey, as was proposed by Mr. Cadell, but by Mr. Steele.]

* Report of Sub-Committee.

The Steam Engine; its Invention, and an Investigation of its Principles, for Navigation, Manufactures, and Railways. By Thomas Tredgold. Enlarged and edited by W. S. B. Woolhouse, Esq., F.R.A.S. Part I., with 60 Plates. London: John Weale.

The name of Tredgold is held in high estimation by all who have to do with the subjects on which he wrote. And very justly: an intellect which could bear up against the apparently unfavourable circumstances of his early life, steadily persevering in a systematic course of diligent self-improvement, and ultimately raising itself to the proud pre-eminence which at length it gained, must have been one of no ordinary standard, and capable of no ordinary achievements. Born in a humble station in life, favoured with no advantages of education but such as his native village afforded, apprenticed early to a cabinet-maker, and employed for five years more as a journeyman carpenter and joiner, it was his own diligent application to studies little cared for by most in his line of life, that cultivated his natural talents, and at once brought them into notice and fitted them for useful and honourable exertion. To these five years of manual labour for his immediate subsistence, and of hard mental toil, by which he laid the foundation of his future fame, succeeded a period of higher employment and greater advantages for his own improvement, in the office of his relative, Mr. Atkinson, an eminent London architect. To this gentleman Tredgold owed much of his future reputation. In his office, in his house, in his library, in the eminent professional characters to whom he was thus introduced, the young engineer met at the same time with the means of perfecting his professional acquirements, and the strongest incentives to labour after professional distinction. And that he did diligently use his increasing opportunities of acquiring knowledge during the seven years that intervened between his removal to town and the publication of his first work, must be apparent from the rapidity with which his works followed one another: important, well-digested, standard works, as they have proved themselves to be. It was during this period that he exhibited that remarkable instance of his intellectual determination and perseverance—the teaching himself the French language, as the key to the treasures of French science. We add the dates of his works: their titles and contents we need not dilate upon, text-books as they are in the profession.

Elementary Principles of Carpentry	1820
Practical Essay on the Strength of Cast Iron .	1822
Treatise on Warming and Ventilating	1824
Treatise on Railroads and Carriages	1825
Work on the Steam Engine	1827

Not to mention several well-known articles with which he enriched the "Supplement to the Encyclopædia Britannica;" new editions frequently called for of his preceding works; and other minor contributions to the stores of scientific information.

With an intellect so active, and so rich in the treasures amassed by a long and unremitted course of study, death alone could have intercepted the series of valuable works which the world expected, and which Tredgold designed. He left behind him plans for future literary labours so numerous, so comprehensive, and so various, that we cannot enough admire the activity of mind that could embrace so wide a range of subjects. Nor do we doubt, that with longer life, our author would have executed, with his wonted ability, much of that which he planned. Counted by years, his life was short; the very activity of mind which makes his intellectual existence, as seen in his works, appear long, prompted him to labours which wore out his bodily frame before his time. To his family and friends indeed his loss was premature, and deep and lasting is the affliction which it has caused; that well-earned professional reward which the father was beginning to reap, unhappily the children have lost by his early death. Whether the interests of Science might have gained by Tredgold's labours in her cause, having been strewn less thickly over a longer course of years, is perhaps doubtful. She has, at least, abundant reason to own, that to few of her sons is she more deeply indebted for the services of their lives, however long, than to him who wore himself out in her cause at the age of forty-one.*

Highly useful and important as are in general the works of Tredgold, we do not hesitate to place in the foremost rank, for utility and value, his work on the Steam Engine. Beginning with a short but comprehensive history of the several discoveries and inventions by which the wonder-working machine has advanced gradually to its present comparatively perfect state, our author proceeds to investigate the principles on which its action depends in the nature and properties of steam; the best proportion of parts by which these properties may be most effectually brought into play in conformity with those principles; and finally to exhibit some of the many applications of the full-grown giant to mining, to manufactures, to locomotion by land and water. Like all Tredgold's works, this is eminently a book for professional men, as affording the soundest and best professional knowledge. But besides, the work on the Steam Engine, is pre-eminently a national work; being confessedly the best philosophical treatise on the construction and uses of our great national glory in mechanical science, the honour of whose invention, as a practically useful machine, we eagerly claim and pertinaciously defend, and whose mighty effects we constantly feel infusing vigour into the heart, and giving vitality to the members of our widely-extended empire.

The earliest application of the steam engine was, as is well known, to the raising of water and draining of mines: even the Marquis of Worcester's scheme had this for its object, his "fire water-work" being, as he expressed it, "an admirable and most forcible way to drive up water by fire." The progressive improvements of the machine have extended indefinitely its use in these respects. By its aid, our miners have penetrated deeper and deeper into the bowels of the earth, and brought up richer and richer mineral treasures. In the "lowest deep" of one age, the mechanical improvements of the next have opened still "a lower deep," not "threatening to devour," but disclosed to bless. So also, in the other department of water lifting, the steam engine has been progressively more and more employed for the distribution of water for civic and domestic purposes. In our cities and large towns, how extensive the ramifications of the water-ways through which it pours its purifying and health-giving streams. The apparatus is, indeed, less picturesque and imposing than the aqueducts of classical times—less poetical than the morning and evening proces-

* An interesting Memoir of Tredgold appeared in the "Scientific Advertiser," No. 3, February 20, of this year. To this we are indebted for the facts given above.

sion of maidens with their water pitchers to the wells, which even yet issues from the gates of Eastern cities; but how much more effectual to the production of health and comfort—the main objects after all—is clearly proved by the statistics of modern cities, as compared with the accounts which we can gain of ancient ones. Still more striking perhaps is the contrast, when we compare the state of our own great towns, supplied in every part with water, in respect of health and cleanliness, with the filth, and its consequent wretchedness and disease, described by travellers as existing at the present day in the cities of the East.

Widely, however, as the original use of the steam engine has been extended, it is probable that the raising of water would be one of the last of its many occupations that would occur to an observer of its applications at the present time. The beautiful contrivances of Watt for converting the alternate and irregular play of the beam into one steady and equable rotary motion, fitted this mighty power for operations of manufacture, endless in number, and multifarious in kind. How shall we classify the works of our factotum giant? Set him to spin, and with strength and skill superior to that of Hercules of old, when Love put into his hands the distaff, he will run you off a yarn which our grandmothers, with their best spectacles, could not have achieved; or, if you please, will with equal ease twist you a cable fit for your proudest man-of-man to trust to in a gale. Set him to weave, and he cares not whether it be the muslin, or the bobbin-net for ladies' ornament, the shirting or the broad cloth for our industrious artizans, and enterprising merchants, and lordly landowners; or the canvass broad and tough, to clothe the lofty masts of our proud navy, and bear our name to every clime of earth. He will roll out for you the iron bar, strong and stiff, fit string to the gigantic bow with which you design to span a noble river; or draw you a wire so fine, that you may weave a gauze so light, that one would swear it is not metal. He will turn for you your lathes, truly and steadily, whether they be loaded with the massive cylinder and weighty axle of engines yet unborn; or whirl lightly round, turning off by dozens the little bobbins on which future thread is to be wound, the "newest article" of the linen-draper's shop. Pass between his powerful rollers the stubborn iron, and out it comes, the thick and uniform boiler-plate, calculated to resist the utmost force of steam; or the smooth and wafer kind of substance which the Birmingham artist moulds into fitting forms, and decks with lively colours in the various kinds of japanned ware. Or try him with another material, give him the dirty rag from the dunghill; he will beat it, and wash it, and tear it, and grind it, and roll it, and dry it, and size it, till out it comes the clean white paper fit for writing, printing, reading, or whatever you please. In short, it would be hard to name a branch of manufacture to which the steam engine has not lent its aid; impossible to mention one which that powerful aid has not improved and extended. It is by this means that we have been enabled, in many instances, to cope with foreign competitors in manufactures for which they enjoyed superior natural advantages; to surpass them far in many others, where their sole but great advantage is the cheapness of their labour. By this means it is, that far as our arms have spread the fame of Britain, farther still have reached her manufactures; and tribes who have never fled before the bravery of her troops, have been clothed, and fed, and humanized, by the ingenuity of her artizans and the enterprise of her merchants.

Nor have the triumphs of steam been confined to the land; not content there to have gained the victory over wind and water power, leaving the windmill to stand bereft of sails, and the water-wheel to gather moss and lichens, while he erects in triumph his sooty head, and earns his black bread by grinding the corn which he has taken from them, he has dared to pursue them to their peculiar domain, and contest with them the empire of the sea. At first, indeed, his exploits were small and cautious; like the timid navigators of old, he crept along the shore, nor ventured out of sight of land. In these experimental cruises, however, he showed his peculiar powers, his punctuality especially, his carelessness of his old rival the wind, his scorn of the power of water, though brought against him in the shape of tides. The increase of our steam navigation has of late years been astonishing. This power has done far more towards uniting us with the continent than could have been the case had we re-purchased the ancient French dominions of our crown at the price of our modern improvements in science. To our sister island, also, we have been bound in closer ties of mutual interest, than conquest or law could have knitted for her. The navigation of both Channels has become in fact as certain and calculable, as formerly it was precarious. Similar effects have attended the more recent establishment of steam communication between our own remoter ports, and various less easily accessible points of the continent. The first accounts of the experiment of steam communication with India too, are favourable so far as that they have effected a vast saving of time in the conveyance of letters; though perhaps it is not possible at present to rely positively on the unfailing punctuality of the arrangements. And last of all the "Sirius" and the "Great Western" have ventured on the wide Atlantic, freighted with good hopes from many, with good wishes from all, who are interested in watching the progressive triumphs of science. We may possibly, before we go to press, have heard tidings of their progress from some recently arrived packet, which crossed them on their path; at any rate, another month will enable us to judge and report on their success.

Though last, not least among the triumphs of steam, we hold his achievements in locomotion on land: he has long submitted quietly to have his strength estimated by horses' power; but now he seems determined to show his power to be above the speed of horses, as before he did that it was beyond their strength—to beat them off the roads, and leave it perhaps to the antiquaries of a future age to discuss what meaning to assign to that strange and obsolete word which figures so frequently in the records of locomotion in early and barbarous times. But not unnecessarily to anticipate the future: the railway system has stood, under the full view of the world, the test of an eight years' trial on the Liverpool and Manchester line, to say nothing of earlier experiments. The triumphant result of the trial is apparent in the completion and practical working of many hundred miles of railway in the British islands, on the Continent, and still more in America; in the works in progress on very many hundreds more, which are by degrees enlarging the domains of steam, as their successive portions are completed. The system must and will go on, despite of all obstacles which the inexperience of their friends and the prejudices of their enemies throw in the way of all new systems. The great effects which will follow from its extensive adoption, we are not here to predict; but hat they will be great, all analogy warrants us in concluding.

From a sketch even so rapid and incomplete as the present, of the progress of steam of late years, it will be apparent that so active and vivacious a subject will require an industrious and attentive pen to chronicle his doings. To borrow an illustration from trade, where the entries in the day-book are so numerous, so various, so important, it will require no slight exertion and diligence to keep the ledger posted up to the current month. Let even a Tredgold give the latest philosophy of the steam engine, the newest and best modes of construction, the most useful and striking applications; yet, pass some ten or a dozen years, and much must be added to make all complete, especially under the latter two heads of the subject. A conclusion so obvious from the progress of science and art, since the previous edition, has been carefully borne in mind by the publisher; and we are happy to see that he has been successful in the choice of an editor, well qualified for a task of no small difficulty. Mr. Woolhouse is already well known in the scientific world by his papers on scientific subjects; and we are happy to see that the volume before us is enriched with an ample Appendix on the important and interesting subject of Steam Navigation. We mention this as the most visible feature of the new edition, striking the eye on a cursory inspection; in a future number, we intend to return to the subject, and enter more into particulars. In the mean time, we congratulate the publisher on the eagerness of his subscribers and the public, which have led him to bring out first the part before us; and to express our hope and conviction that he will find no reason to regret the very liberal style in which he has got up the present edition of this most valuable work.

A few Plain but Important Statements upon the Subject of the Scheme for supplying Leeds with Water. By Henry R. Abraham, of London. March, 1838.

It was our original intention to make some remarks respecting the supply of water to the town of Leeds, having heard some extraordinary statements respecting the evidence which was given before a Committee of the House of Commons last session. We fully expected that we should be able to obtain a sight of this evidence; but up to the present time we have not succeeded in procuring it, and this is the reason of our silence on the subject.

The above pamphlet, which comes from one of the disputants, is very ably written, and contains much valuable and practical information relative to water works. We shall not enter into the disputed question for the reasons before stated, but shall simply confine ourselves to laying before our readers rather a copious extract from the pamphlet, and leave them to judge for themselves of the merits of the case:—

* * * * *

I shall now investigate the subject for you in the plainest manner; and I will give the utmost latitude to my calculations in favour of your scheme.

You have stated, that before the works can be completed 210,000 persons will require water.* In London, the very smallest average quantity supplied for each person is twenty gallons *per diem*;† while the quantity supplied by

* Mr. Leather's evidence in the Committee of the House of Commons.

† The South London district—the ill supply of which was noticed in Parliament.

the New River Company averages forty-eight gallons; and even this supply is found insufficient to meet all demands. Let us, however, take the smallest of these *per diem*, 4,200,000 gallons will be necessary.

It is, however, imagined, that the Leeds people will use *much less than the worst supplied of the London districts!*—Why, I know not. Nevertheless, Mr. Leather states, that 1,200,000 gallons, or about half that quantity, would suffice; and as it is not pretended that Leeds can have more than this quantity of water, we will proceed to inquire from whence can be obtained the 1,200,000 gallons *per diem*, or 70,080,000 cubic feet per annum.

At Eccup and Alwoodley, near Leeds, there are springs of water whose conflux yields a run of 230 gallons per minute, independent of any assistance from rain: this gives 19,395,947 cubic feet per annum. It is asserted that the country converging round these springs affords 1,200* acres of drainage, and will assist to complete the quantity of 70,080,000 cubic feet. We must therefore ascertain, first, the quantity of rain which will every year, at the minimum experienced data, be likely to fall upon this tract of land.

We must next ascertain what quantity will be lost in filtration, irrigation, and evaporation in its meanderings and lazy percolations towards the reservoir, and then, by well-known approximate rules, deduct the quantity evaporated in the reservoir.

1st.—The fall of rain, which I will compare with that of the district in question, shall be that of a very wet adjoining county, Lancashire, for which I have accurate observations for twenty-two years,† the lowest of which is 20·4 inches. In order, however, to avoid the charge of taking an extreme case, I will take the next lowest year, or 26·6 inches, and calculate from the average of the two, we then have 23½ inches fall of rain.

Let us examine next the fall of rain in Yorkshire.

	Inches.
York‡—Professor Phillips gives for 1833-34	25·7
Mr. Cholmeley's, at Brandsley, twelve miles from York, northward, upon ground higher	24
Middlesex—1836§	23·9
General average (London and Yorkshire)	22·1

The fall of rain is occasionally in Yorkshire 20 and even 18. If, therefore, we adopt 23½ inches fall, we shall not estimate from an extreme occurrence, but from one far above that which prudence should induce us to rely upon.

Now, 1,200 acres of ground, 23½ inches deep in water, gives per annum 639,787,500 gallons, or 102,366,000 cubic feet. From this the natural consumers—evaporation and filtration, will first have their share; and irrigation and husbandry must also be satisfied.

Evaporation scarcely ever stops; it goes on winter and summer, day and night, in frost and snow—ice passes into vapour as well as the shallow waters which waste in the summer's sun. While the rain is pouring into water, vapour flies rapidly from it.

In fact, evaporation is and must be equal to the fall of rain.‖ The quantity of water arrested in its progress by grass, weeds and fallow land, and that which penetrates through sandy fissures deep into the bowels of the earth, for the supply of lower levels, is considerable. Were it not for this wonderful arrangement of the All-Wise, our valleys would be swamps—our rivers torrents, rushing through deeply cut ravines—our hill-sides dry wastes. The observations of disinterested men of science, the research of those anxious to benefit mankind, enable us to form approximate estimates of the quantity lost by these causes.

I have collected them for my own instruction—I lay them before you for yours.

After a shower of rain, evaporation proceeds most rapidly, and while the quantity fallen dribbles to its lowest level on an extended surface, the motion favours the process, and the loss is very great.

In the case before us, the country presents a surface which is an eager recipient of wet, and excepting only a few tables of clayey land, which are undrained, and which suffer the water to pass away altogether in evaporation, it absorbs quickly. Numerous seams of coarse grit, the debris of the surrounding hills, and beds of porous irony loam, in great extent, occur in the valleys, quickly carrying away by filtration the rain as it falls. After a very mature investigation of these local features, and with great anxiety to promise as large a supply as I dared to expect, I could not infer in the estimate which I laid before the town, that one-half the fall of rain on such a country could enter a reservoir. The actual quantity to be received into the reservoir will be considerably less than one-half; but we will calculate that one-half shall, by good management, be secured, or 51,183,000 cubic feet.

We will now proceed to fix the loss in the reservoir: the quantity of rain which falls as is well known, varies in abundance, according to the season; that is, a large quantity will fall in autumn—a small quantity in spring and winter. Evaporation also varies: in summer height $\frac{3}{10}$ of an inch being the quantity vaporized each day; in autumn and spring $\frac{2}{10}$, and in winter $\frac{1}{20}$ of an inch *per diem*. This is less than allowed in canal works, but I wish to make your prospects as bright as possible. From observations made for thirty-four years,* it has been ascertained that in winter and spring about $\frac{1}{5}$ in each quarter of the annual fall occurs, in summer $\frac{1}{4}$, and the remaining in autumn.

	Cubic Feet.	Cubic Feet.
Brought forward		51,183,000
Allowing then for winter $\frac{1}{5}$ of the quantity in cubic feet, then $\frac{1}{20}$ of an inch in surface, taken over thirty acres, for ninety days, the reservoir being forty-five acres in capacity, but not full, *the evaporation will be*	490,050	
Spring $\frac{1}{5}$ of the quantity again, less $\frac{2}{10}$ of an inch *per diem*, over an increased surface of reservoir, say thirty-five acres for ninety days . . .	2,286,900	
Summer $\frac{1}{4}$ of the quantity over a still increased size, say forty acres, because it is now exposed in two reservoirs, for ninety days, at $\frac{3}{10}$ of an inch *per diem*	3,920,400	
Autumn, the remaining quantity over forty acres, for ninety-five days at $\frac{2}{10}$ of an inch *per diem* .	2,758,800	
		9,456,150†
Total quantity of rain in cubic feet per annum		41,726,850
To this add the quantity supplied by the springs		18,501,120
Making a total of rain and spring-water per annum		60,227,970

But this will not supply the minimum quantity of 1,200,000 gallons *per diem*, although not a minimum fall of rain.

Thus, at starting, there is a deficiency *per diem* of 27,000 cubic feet, or 168,750 gallons. Having ascertained that in round numbers 60,250,000 cubic feet may be attained in the course of one year, let us examine in what way it is to be appropriated for use by Messrs. Leather and Fowler.

A reservoir is to be formed at Eccup, *forty-five acres in area, which is to be* 46½ *feet in depth* at the dam-head, and capable of holding about 250,000,000 gallons. The conduit from this is to be two feet from the bottom,‡ and the conduit itself thirty inches diameter, and it should have a head of a foot to work with; then above 7,000,000 cubic feet must be deposited before the service can be carried on with regularity. At Weetwood another reservoir is to be formed. Before any water can flow from this reservoir, 3,500,000 cubic feet must be deposited below its service pipe. Therefore, including water in transitu, about eleven millions cubic feet lie stagnating and evaporating in perpetuity.

Without commenting on this most eccentric method of supply, we will imagine all ready to receive the springs and rain. To give every advantage to the case, we commence in the wettest season, autumn—

	Cubic Feet
Then twelve weeks run of springs will yield	4,625,280
And twelve weeks rain, less the evaporation, will yield . .	13,696,260
First quarter's supply	18,321,540

The service may now commence, and after deducting the eleven millions cubic feet necessary for the action of the works, there is left as available stock nearly 7,500,000 cubic feet.

Next, after the wet season, however, follow two dry quarters, and they will not afford even the reduced average, daily quantity, without draining from stock. A quantity must therefore be secured from the stock, which is now at its maximum.

		Cubic Feet.
The winter and spring demand for 180 days . . .		30,799,800
While the product of the springs . . .	9,250,560	
And rain together for both quarters, is only .	16,688,950	
		25,939,510
Deficiency		4,860,290

Leaving the above deficiency to be supplied from the stock, which is now reduced to 2,639,710 cubic feet. Summer next arrives, requiring

		Cubic Feet.
Ninety-five days' supply, or		15,675,760
The fall of rain and the springs	4,625,280	
Conjointly furnish	16,688,958	
		21,314,238
Excess of supply		5,638,478

Thus the year being ended, the reservoirs do not contain 8,000,000 cubic feet conjointly, ready for service, although they had three months' supply poured into them to start with; and it is obviously plain that the only water which can possibly lie in them, will be the excess of the wet quarter, which is to assist the dry seasons, and this excess we will find by deducting the demand from the supply of the autumn quarter.

	Cubic Feet.
The supply is, as we have already shown, for the wet season .	18,321,540
The demand, or rather the regularly assignable portion for ninety days, of 1,070,439 gallons per day, is . . .	14,850,720
	3,470,820

* There are not, however, 1,200 acres for drainage. Upon my survey, I calculated no more than 1,050, and I comprehend a larger practical district.

† Hanson's Meteorological Chart. ‡ Report British Association.

§ Scientific Register.

‖ Those who are not accustomed to observe large quantities of water, are apt to regard evaporation with equal *nonchalance* to that which a coachman views the steaming of his horses. Thus Mr. Leather ADDED THE DEW; stating that the rain was thirty-one inches, and the dew five inches, which equals 36.—*Vide* his Evidence at Westminster.

* Howard's Climates. † This is an extreme quantity.

‡ Mr. Leather's evidence.

But Oldman's reservoir at Weetwood, by the evidence, is to hold 3,500,000 cubic feet to the service pipe, and it will take a further quantity of 4,000,000 cubic feet to fill it; there will be but 4,000,000 cubic feet water at any time for store in the Eccup reservoir.

If there be a shadow of truth, an approximation even to fact, in the foregoing, what can justify the formation of a reservoir covering an area of sixty acres, forty-six feet deep, capable of retaining about 250,000,000 gallons, and costing, if properly constructed, a sum of not less than 25,000*l.*? and what can justify the pledge that 1,200,000 gallons *per diem* shall annually be sent to Leeds? Beyond all, in what way will Mr. Leather convince you that, from the same capacity of source, 2,000,000 gallons *per diem* shall be sent to Leeds when the town demands that quantity? If the Eccup source will supply 2,000,000 gallons in ten years' time, it can do so now. Let it be granted that the next year's rain, instead of the moderate and safe calculation just adopted, mounts up to Mr. Leather's quantity *(but without the dew)* i. e. thirty-one inches daily. Even allowing this, the supply could not be effected, because the amount of rain and springs is then only 73,500,000 feet, and the demand is 70,000,000 feet; but there must be 3,000,000 cubic feet in Oldman's reservoir up to the service pipe, and 7,000,000 in the Eccup, so that a deficiency exists which, without the DEW, cannot be made good, and nothing is left for the reservoirs.

* * * * * * *

I will now briefly sum up the points for which I have begged your attention, in order to show that neither data nor calculation has justified the projected outlay or scheme—that in fact no investigation has been made at all in the matter.

There is no evidence to show that 1,200,000 gallons *per diem* will be sufficient for the town, as a general and universal supply; but, on the contrary, practical experience shows, that if the *poor* are to be supplied, streets watered, and fires extinguished, more than 2,800,000 *gallons* will be necessary.

Mr. Leather states, that in ten years the town of Leeds will require 1,800,000 gallons *per diem*; but, by the same comparative scale, the least required quantity must be 4,200,000 gallons. It has been shown, however, that only 1,031,000 gallons *per diem* can either now, or at any future time, be depended upon from Eccup.

It has been shown that the reservoir at Eccup can never be filled; from whence then, in the first place, is the present supply to be had? and, in the second, in what way is the increased supply to be obtained?

If the source will only deliver 190,000 cubic feet *per diem* in 1837, how shall it deliver 288,532 in 1851,* when the increase will be required? But why, in the face of other towns requiring double the supply alleged to be necessary for yours, do you credit the representation that the less proportion will suffice? Examine this statement of what six of the London Companies supply *per diem*, and judge of its correctness.

Grand Junction, 72½ gallons; Southwark, 31; New River, 48; West Middlesex, 36½; Chelsea, 33⅓; East London, 24 gallons.

The average of these is more than forty gallons *per diem* for each individual, and can you credit that the Leeds necessity, with all its smoke and dirt, shall require only one-fourth of such a quantity?

* Mr. Leather's evidence.

A New System of Scales of Equal Parts, applicable to various Purposes of Engineering, Architectural, and General Science. By CHARLES HOLTZAPFFEL. London: 1838.

MR. HOLTZAPFFEL could not have done a better service for the profession, than turning his attention to the construction of scales suitable for their purposes. The difficulty of obtaining scales, accurately divided, has long been felt. They can only be obtained at a very few mathematical instrument makers, who charge a most exorbitant price for them. To obviate this evil, Mr. Holtzapffel has constructed scales of almost every description on card paper, divided by an engine, and which he is enabled to sell at the trifling sum of ninepence each. He also undertakes, at a small additional charge, to make any single scale, agreeably to order, when it is required for a specific purpose. We have for many years been in the habit of using scales made of paper, both for estimating and drawing, on account of their convenience; the objection to them is the loss of time in making, and also their inaccuracy, in consequence of being obliged to divide them by hand; these inconveniences are removed by adopting Mr. Holtzapffel's scales, which we certainly shall do in future. We have very carefully examined several of the scales, and have much pleasure in testifying their accuracy and utility. We very strongly recommend them to the notice of the profession, who, we doubt not, will very readily adopt them. They are not only made on card paper, but may also be had divided on ivory, brass, or other metal. Mr. Holtzapffel, in the above pamphlet, fully describes the utility of the various scales which he manufactures. We cannot do better than give the following extracts from his work, in explanation of their construction:—

I set out with the determination to economize to the utmost the mere fabric of the scale, by using the card paper which I had found to answer so well; to follow the method of dividing all the scales on their edges, so that there should be no occasion for the use of compasses, to the injury both of the scale and paper, making besides two operations in place of one; and to limit each scale to a single line of divisions, so as entirely to avoid the perplexity and confusion arising from the crowding together of several lines of divisions on the same piece of boxwood or ivory, which tends to distract the mind from the drawing, to which it ought to be exclusively devoted, to the instrument, which should be of no more concern than the fingers.

Card paper, the material selected for the purpose from its many appropriate qualities, possesses but one inconsiderable disadvantage, namely, its trifling change of length from atmospheric influence; as however this *same change* is as constantly going on in the paper to which the scales are applied, it rather deserves to be considered as a compensation than as a defect. But I shall presently speak of this more particularly.

On the other hand, the card scales possess the following advantages. *From the economy of the material*, we may obtain, for the same expense, an increased collection of longer scales on distinct slips, free from all liability to twist and warp; the sub-divisions, which are minute, extending generally over eighteen inches. From the *flexibility of the card scales*, we are saved the continual trouble of shifting the instruments from place to place on the drawing board, to make room for the entire length of the scale at any particular part; this quality likewise admits of their easy application to curved surfaces and lines. *The white card paper* offers the most striking contrast to the black lines, the scales are consequently very legible; and by using various light-coloured cards, different series of scales may be easily distinguished from one another. The nature of the material further admits of the employment of the printing-press or the pen, for any numbers, titles, or explanations; and also of the restoration of the edges two or three times, by careful cutting. *The card scales, being very thin*, offer but little impediment to the drawing squares which may be laid over them; and in shading drawings by means of equi distant parallel lines, this circumstance is very desirable, for regulating the uniformity of the ground. They are portable and compact, a large collection of them can be kept in the paper cases, with separate compartments provided for them, without confusion or injury.

The change of length in the card scales before alluded to, is only a comparative error, as all the materials employed in the construction of scales, and also in their ultimate application, are subject to the same defect.

On the continued examination of several scales, made from different sheets of card, some being exposed in rooms at the ordinary temperature, and others placed in the open air, the atmospheric variation in length was found in general to be about the one-hundredth of an inch in the foot, and in extreme cases three or four hundredths in the foot, from the standard. And on the inspection of a very considerable number of the finished scales, previously to their being made up in packets for sale, this was fully substantiated.

To avoid introducing this source of error during the process of manufacture, it may be observed, that the card is preserved in its ordinary dry condition throughout the same, and that *every individual scale* is ruled in the dividing engine after the figures have been printed.

But we must not forget to observe the variation which is going on at the same time in drawings. This may be easily done by any one. I took a sheet of drawing paper, and placing one of the card scales across the middle of the same, I made, very carefully, with the ordinary drawing instruments, two fine ink lines, partly on the card and partly on the paper, so as to be certain that the space between the lines was in the first instance the same. These lines were marked A A A A; similar lines marked B B B B, were made on placing the card at right angles to its former position; and the same thing was done with a wood scale, employing the letters C, D. The lines were about one foot asunder, and the papers, &c. (as I used several, marked in sets 1, 2, 3, &c.) were placed under the same circumstances for the twenty-four hours previously to making the test marks, to bring them to the same condition.

On exposing them alternately for a day or two to the damp open atmosphere, and to the dry air of a warm room, the lines made on the paper and the paper scales, in which the materials were similar, approached very considerably nearer to agreement than those upon the dissimilar materials, the paper and wood.*

We add the compensation balance to a watch, to adapt that measuring instrument to the change of circumstances under which it is placed; should we not, by parity of reasoning, employ a compensation scale, for the measurement of our drawing papers, one similarly influenced to the thing measured, from the identity of its fabric?

I am satisfied that a fair examination of all the circumstances, for and against the new card paper scales, will show them to be fully entitled to an extensive employment.

Two useful elementary works, written in a plain and intelligible manner, easily understood by the uninitiated. They are published at the trifling sum of one shilling each.

ORIGINAL PAPERS AND COMMUNICATIONS.

RALPH REDIVIVUS.—No. 5.

THE CUSTOM-HOUSE.

Like that which formed the subject of my last paper, the building I have selected to speak of in this has undergone a very material change, although but a partial one, the alterations having been confined to the central division, in which is situated the Long Room. But the present case of metamorphose differs considerably from the one before spoken of, being by no means so happy a one. On the contrary, instead of gaining anything whatever, the original design has lost considerably by the transformation that has been made in it; losing, in fact, the only good and redeeming feature it possessed.

Taken as a whole, Mr. Laing's design exhibited very little invention or consistency. The centre, consisting of nine large arches above the basement, filled in with windows, and without any other windows above them, possessed character and propriety, and announced most distinctly that there, on the upper floor, was the Long Room. The large bridge-like arch below, forming the entrance to the King's Warehouse, was also a good feature, while the two long bas-reliefs, in the attic, between a space of equal extent, which was occupied by an inscription, gave an air of dignity and finish to the whole of the centre; which had, moreover, the merit of possessing some novelty of physiognomy. But after this the architect seems to have been quite *au bout de son metier*, being unable to devise anything either better in itself, or more original for the wings, or rather, extremities of his building, than the stale expedient of bedizening those parts with columns, between which are holes in the walls for sash windows. It avails little to urge that those columns, being copied from a pure Greek specimen, the Ilyssus Ionic, are beautiful, because all the merit a modern architect can assume to himself for such things, which are avowedly not of his own invention, depends upon the felicity with which he can make them in some degree his own, by tasteful appropriation of them in his design, and his rendering all the rest perfectly of a piece with them. Although a beautiful flower, a rose would be an exceedingly ridiculous appendage to a judge's wig, were it stuck upon that very venerable respectable head-dress.

I may be in error, nay, supposing some people to be in the right, most egregiously so indeed; but it certainly does appear to me, that wherever such adventitious decoration—as that of columns, without there is any evident necessity for them—is introduced, it ought, at all events, to seem absolutely called for; not, indeed, by the exigencies of the building, but by the character of the design. As far as that is concerned, they ought to appear essential to it. Instead of which, we more frequently than not find them resorted to, and dragged in for the nonce, as a mere shift—a shift, by-the-by, now sadly the worse for the wear—with the hope of thereby concealing the absolute inanity and poverty of the design itself, and its utter want of all expression and character. To stick up columns, where there is nothing whatever in any sort of accordance with them, is one of the commonest and most vulgar sins of which an architect can be guilty, and that to which dulness is sure to betake itself.

Most certainly, there was nothing in the design of the Custom-house to justify them; on the contrary, they served no other purpose than to throw the whole out of keeping, and to cause what would else have amounted only to plainness, to appear downright meanness of the most shabby and parsimonious kind.

There is no trusting to proverbs, unless they are interpreted with a little *nous;* notwithstanding which, architects are apt to put implicit confidence in the one that tells us, "fine feathers make fine birds." They would act more wisely—I might say they would act less absurdly, than they now frequently do—were they to call to mind the fable of the "Jackdaw in borrowed plumes;" for it cannot be denied that we have many buildings, which, notwithstanding they are bedizened out with columns of most classical cut, cut but a very sorry jackdawish figure themselves, and are some degrees more disgusting, ridiculous, and preposterous than they would be, did they show themselves forth to the world in their native, undisguised cockneyism. Can anything, for instance, be more exquisitely barbarous than the Church of All Saints, at Poplar, which certainly gives the lie direct to the proverb just quoted, proving by ocular demonstration, that Greek columns will not of themselves constitute a Greek portico, but, on the contrary, may be made to stand like sulky appendages to a building in which there is not a single particle of Grecian taste? By what piece of good luck that truly ignominious design happened to escape the pen of Welby Pugin, when hunting about after modern monstrosities, it is difficult to guess. However, I must not permit that egregious specimen to detain me now, but resume my professed subject.

The Ionic columns may, in some degree, be thought an excuse for there being no dressings to the windows, for the simple reason that they leave no room for them, the bare apertures having even now the appearance of being squeezed into the spaces between the columns, and quite cribbed up; yet surely this was of itself a sufficient reason, let alone every other, why there should not have been columns at all; for, surely, if they can neither be made to accord with the plan decided upon, nor be rendered of any value in the design, it is on every account better to omit them, and to have recourse to some other mode of decoration. For what was thus worse than uselessly expended, all the windows, at least, might have been so embellished, as to keep up consistency of character throughout. Matters are made not at all better, but in some respects very much worse, by three of the windows in each of these divisions of the front, namely, those over the doors in the basement, having added to them, by way of ornament or distinction, a mean shelf-like cornice, supported on brackets, but without any kind of architrave around the opening itself; the effect of which is most paltry. Glaring as the solecism is, no doubt it has its admirers who consider it a beauty, since I find it has since been adopted in some of the ginshops about town, and other buildings of that kind. In them it is offensive enough, but here doubly so, because at utter variance with anything purporting to be in the Grecian style, or affecting even the slightest approach to Grecian taste. Our chief consolation is, that after all it merely constitutes an additional defect in what is so radically bad in itself; that a defect more or less becomes of very little importance as regards the building itself.

Let us proceed to examine Sir Robert Smirke's portion of the front, as altered by him, when he was called in to repair the damage it had sustained by the falling in of the Long Room, on the 26th of January, 1825. This middle compartment was, as I have said, by far the very best portion of the whole; it possessed character and propriety. It told plainly enough that there was the Long Room, occupying the whole extent between the wings. Well, what does Sir Robert do? Whether it was that he intended to give us satirical illustration of *reform*, I do not take upon myself to decide; therefore merely say, that if such was his intent, he succeeded admirably. At all events, the specimen he has here given us of architectural reform, is enough to make us sicken at the very name. Not content with removing what was good, he substituted for it a host of incongruities. In its first state the centre of the building accorded with the internal plan, and showed itself to be what it really is, one long and lofty room. It is now made completely to falsify such arrangement, by being subdivided into five portions, consequently suggesting the idea of there being as many rooms on a floor in that part of the edifice. So far, then, the exterior is a mere mask, and one of the least excusable kind, because it substitutes littleness for continuity and grandeur. It exhibits, moreover, that quintuple division of a front, observable in most of his other designs, viz., a centre portico, and an extreme compartment at each end, where the order is again resumed, after being omitted in the intervening divisions—as we behold in the Post Office, Covent-Garden Theatre, &c. Here, too, he has brought out a projecting portico, but with so little regard even to the appearance of utility, as to show that it is of no service whatever, there being no means of access to it from the room behind it, as the windows are several feet above the floor, neither is the centre one carried down externally so as to have the appearance of opening into the portico. From a near point of view, this, it must be owned, is not very discernible, because the bottom of the windows cannot then be seen. Yet then it is equally obvious that if it is not a sham one, but a *bonâ fide practicable* portico, where persons may walk out, they must not venture into it in other than a sober state, there being neither balustrade nor anything else to guard them from falling down. Well, but putting all utility out of the question, is it not a good architectural feature in itself? Verily, I think not; on the contrary, that it betrays much that is decidedly erroneous and defective, even in point of composition. In the first place, the number of columns here does not exceed that in each of the wings, which not only occasions monotony,

but also some degree of anticlimax. This colonnade should at least have been octastyle, if not more, in order to give some little degree of emphasis to the centre. It is true, that although hexastyle, like the other two, this range of columns is somewhat longer. Even this, however, is attended with an obvious defect, because these advanced and perfectly isolated columns are considerably wider apart from each other than those which, being quite close against the wall, would have better borne to be wider apart. In fact, the intercolumniation is not Greek, but is almost *aræostyle*, for the order, as any one may convince himself, by imagining a pediment over the columns, when he would find it much wider in its proportions than almost any other hexastyle portico we have. Let me not be told that the architect could not make his intercolumns narrower, being under the necessity of spacing his columns according to the piers and windows behind. Such a plea is not for a moment available, for, admitting that he could devise no mode of arranging the windows themselves differently, the question then to be answered is, what put it into his head to have columns there at all, since, as has already been shown, that so very far from answering any purpose, the colonnade boldly disavows any kind of utility? After this comes another question—why did not Sir Robert carry up the order here to the top of the building, increasing the diameter of the columns accordingly, and thereby decreasing the width of the intercolumns? Had he done this, and carried his colonnade the whole extent of the Long Room, the centre would then have preponderated, as it ought to do, in the composition. From his not having adopted this course, another grievous defect has arisen, for he has been obliged to introduce a kind of upper story—attic it cannot be called—above the order; so that the Long Room appears to be cut up all ways, horizontally as well as vertically, and the whole centre to be depressed by an excrescence on the top of it, quite as ugly as that on the top of the Mansion House, and not even one hundredth part so picturesque.

All this, it must be confessed, is exceedingly provoking and vexatious; the only consolation in the whole matter, is to discover how cheaply the reputation for classicality of taste may be earned, and how more cheaply still it may be maintained. Nothing whatever of the spirit of Grecian architecture is discernible throughout the whole; and what is still worse, we have nothing as an equivalent in lieu of it. On the contrary, there is a most puerile affectation of Greekism, which the architect has dragged in, without satisfying any demand of beauty, at the same time that he has violated common sense. Besides the reasons already adduced for the omission of columns, one very sufficient one was, that the colonnade must come where there would be windows behind it, unless he had chosen to light, if not the whole, the centre of the Long Room from the ceiling. Any man who understands anything of Grecian architecture, must also know how next to impossible it is to keep up its character, if windows must unavoidably be introduced within a portico or colonnade, and will therefore take care never to put a portico where he cannot get rid of windows. But, even, in the management of his windows, Sir Robert has committed a most egregious solecism, for while he has bestowed cornices upon those within the portico, he has left the three on either side of it comparatively bare and unprotected, having merely architraves; the consequence of which is, that this front to the Long Room, now cut up into five divisions (containing thirteen windows, instead of nine, as originally) looks all the more disconnected. In fact, it appears to have been a design for an entire front, taken and inserted between Laing's wings. Nevertheless, Mr. Wightwick says,—at the same time qualifying his opinion with a "perhaps"—"that the new centre gives a more harmonious character to the front as a whole;" adding, however, "but that the old centre, individually considered, was a far superior composition—simple, grand, and characteristic." Most undoubtedly, therefore, the best luck that can now be wished to Sir Robert's piece of architecture is, that it may take example by that of its predecessor, and fall down—yea, "leave not a wreck behind."

ON BUILDING MATERIALS.

No. I.—STONE.

It is reported that the Commissioners of Public Works are about to open a Museum, containing a collection of the various kinds of stone and other materials used in building, for the inspection of those architects or engineers who may be employed in the erection of public buildings. The importance and utility of such a measure cannot for a moment be questioned, and I trust that its advantages will not be limited to the architects engaged in national works alone, but that every professor of the science will be allowed the opportunity of inspecting the collection, and thereby becoming practically acquainted with the internal resources of his own country; indeed, when we consider the great importance of a thorough knowledge of the various materials used in the constructive arts, it becomes a matter of some astonishment that this plan should not have been adopted by the Institute of British Architects, or of Civil Engineers, long ere this, especially as such a collection might be made with but little comparative expense, and would soon be increased to a considerable extent by the donations of its various members. How little knowledge is to be obtained from books, and how few publications consider the value of this kind of information, is well known to the profession; and yet what numerous errors into which the young practitioner has frequently fallen, may be attributed almost solely to a deficiency of knowledge on this point. Until very lately, our architects and engineers have seldom extended their inquiries beyond the limits of their own immediate neighbourhood, and even those whose practice and experience have rendered them eminently qualified to give information upon those branches of their profession, have seldom communicated them to the world with sufficient clearness to enable others to profit by their superior knowledge. It is these considerations which have induced me, in the few following observations, to attempt a short description of the principal kinds of stone, which, in the course of practice, have come under my own notice; trusting that this example may induce others of superior knowledge and greater experience to communicate their more valuable information upon subjects connected with building materials generally. I shall attempt no geological classification, but shall confine myself to that style which is simple and intelligible to the humblest reader, while, at the same time, it will not (I trust) be quite valueless even to the most talented or experienced.

The great importance of stone in building may be inferred from the fact, that few if any nations have attained superior excellence in architecture where this material has not abounded; and it would not perhaps be too much to say, that had it not been for the granite rocks of Egypt, and the marble quarries of Pentelicus, we should never have had either the temple of Apollinus Magnus or the Parthenon; and there remains but little doubt, that the plentiful supply of these materials was one great cause of the superiority of those nations in the constructive arts. Great Britain abounds with almost every variety of this valuable material, from the hardest granite to the finest and softest limestone. In London indeed for many years Portland stone was almost the only kind used in building; Bath stone was afterwards introduced, about fifteen or twenty years back; and subsequently Park Spring, Bramley Fall, and many kinds of granite became common. But there still exist, in various parts of our island, vast quarries of different kinds of stone which are even now but little known beyond their own immediate vicinity. In the western parts of Kent, and the eastern parts of Sussex, sandstone abounds in great quantities; but it was not until Mr. Decimus Burton commenced building at Tunbridge Wells, that it became an article of general use. Within the last twelve years, the new churches of Tunbridge Wells and Southborough, the whole of Calverley Park, together with some hundreds of private buildings in that neighbourhood, have been erected of this stone; and although of an inferior quality, its introduction has greatly improved the character of the architecture of that locality. This stone is of a warm yellow colour, interspersed with streaks of deep brown or red, and sometimes curiously grained like mahogany. It is fine in texture, and stands frost tolerably, but absorbs moisture considerably. It does not become harder by exposure to the air, and is too soft to bear a very sharp arris. In building with it, it is usual to line the interior of the walls with four-inch brickwork, to keep them dry. This stone extends over a great part of Sussex, and is frequently found in vast fragments, presenting the most curious and grotesque forms.

In the more eastern parts of Kent, Kentish rag has been for many years the chief stone employed in building, and the excellence of its quality may cause some surprise that it has not been more extensively used. It is of a dark grey colour, of very firm texture, and great durability. The Asylum, the New Prison, and the New Church at Maidstone, have all been erected with it; and when well burnt, it produces a lime but little inferior to the Barrow lime of Leicestershire.

Proceeding from the south to the northern parts of Great Britain, we shall find still larger quantities of this useful material. In the county of Lancashire, the Runcorn stone was formerly much in use. Most of the public buildings of Manchester and Liverpool are built of this stone, which is of a pale, and sometimes of a deep red colour, coarse in grain, and frequently very soft. It comes principally from Runcorn Gap, Cheshire; but its use has lately been superseded by the introduction of the Huddersfield stone, from Huddersfield, in Yorkshire. This stone is of a very superior quality, and was used in the erection of the Royal Institution, the Infirmary, and many of the public buildings in Manchester. Its colour is light grey, its texture fine and compact, it stands the weather well, and bears a very sharp arris. Another variety of this stone, called the White Huddersfield, is used principally for inside work, and, in appearance, resembles the Block fire-stone, from Ryegate, Surrey. It is extremely hard, and fit for the finest work, but does not resist the action of the atmosphere so well as the former; it is

frequently used for window-sills and copings, but is most usually for stone-staircases, hearths, chimney-pieces, &c. The Alderley Edge stone is another variety, which has latterly come into great use in Manchester and Salford. This is a sandstone of excellent quality; its colour is a warm yellow, its texture uniform, and although not very hard, it will bear a very sharp arris. I employed it in the erection of several buildings in Manchester, and although not equal to the Huddersfield, it gave great satisfaction. It is principally procured from the quarries of Sir J. T. Stanley, at Alderley Edge, in Cheshire, about ten miles from Manchester.

Near the same spot are quarries of a coarse sandstone, called Summet stone. In appearance this stone closely resembles the Bramley Fall, which has lately come so largely into use in the metropolis; but it is more loose in grain, and although capable of resisting the weather to a great extent, is apt to split with frost. It is very useful for gate-piers, copings, &c.

Derbyshire alone abounds with vast quantities of almost every kind of stone necessary for the architect, the engineer, or the sculptor, from the coarse hard sandstone, almost equal to granite, to the fine-grained limestone, which will bear a polish nearly as perfect as marble. I have now before me no less than ten distinct varieties of Derbystone stone, all of which are excellent in quality, and as various as the names by which they are designated. The neighbourhood of Chesterfield abounds with various kinds of sandstone, the chief of which is of a reddish white, and sometimes of a deep red colour. The grain of most of these is coarse, but exceedingly firm and compact, and they stand the weather well. Of these kinds, the new church at Chesterfield, and many of the bridges of the North Midland Railway, are now erecting. Another variety is of a yellowish brown colour, much finer in grain than the former, and more suitable for nice work, but not quite so durable. In Darley Dale are quarries of limestone, from which vast masses almost of any required dimensions can be procured. Its colour is a light grey, and its grain exquisitely fine and hard. I am informed that the Birmingham terminus of the London and Birmingham Railway is about to be erected of this stone. In the more central and southern parts of Derbyshire are vast quantities of limestone, of the finest quality, and superior, I think, to that of Darley Dale. The neighbourhood of Matlock, Ashover, and Middleton, and many parts of the High Peak country, present immense rocks of this beautiful material. It is nearly white, and as fine as Italian marble. The Derbyshire shell marble is of this quality, and is thickly embedded with marine shells, and when polished, is equal in beauty to many foreign marbles, although so plentiful in Derbyshire that it is used to mend the roads, or is burnt into lime. I never remember seeing but one specimen in London, which forms the top of a table in the British Museum; although at Chatsworth, the beautiful seat of the Duke of Devonshire, some very elegant columns, &c. are formed of it. In some parts it is of a deep red colour, but most commonly grey and white, and is much used in the neighbourhood for chimney-pieces. Black marble likewise abounds in Derbyshire, but its quality is somewhat inferior.

C. L. O.

HAGUE'S PATENT HYDRAULIC MACHINE.

Specification of the Patent granted to John Hague, of Cable Street, Wellclose Square, in the Parish of St. George in the East, in the County of Middlesex, Engineer, *for Raising Water by the Application and Arrangement of a well known Power, from Mines, Excavations, Holds of Ships or Vessels, and other Places where Water might be deposited or accumulated, whether from accidental or natural Causes, and also applying such Power to, and in giving Motion to certain Machinery.*—Sealed May 9, 1836.

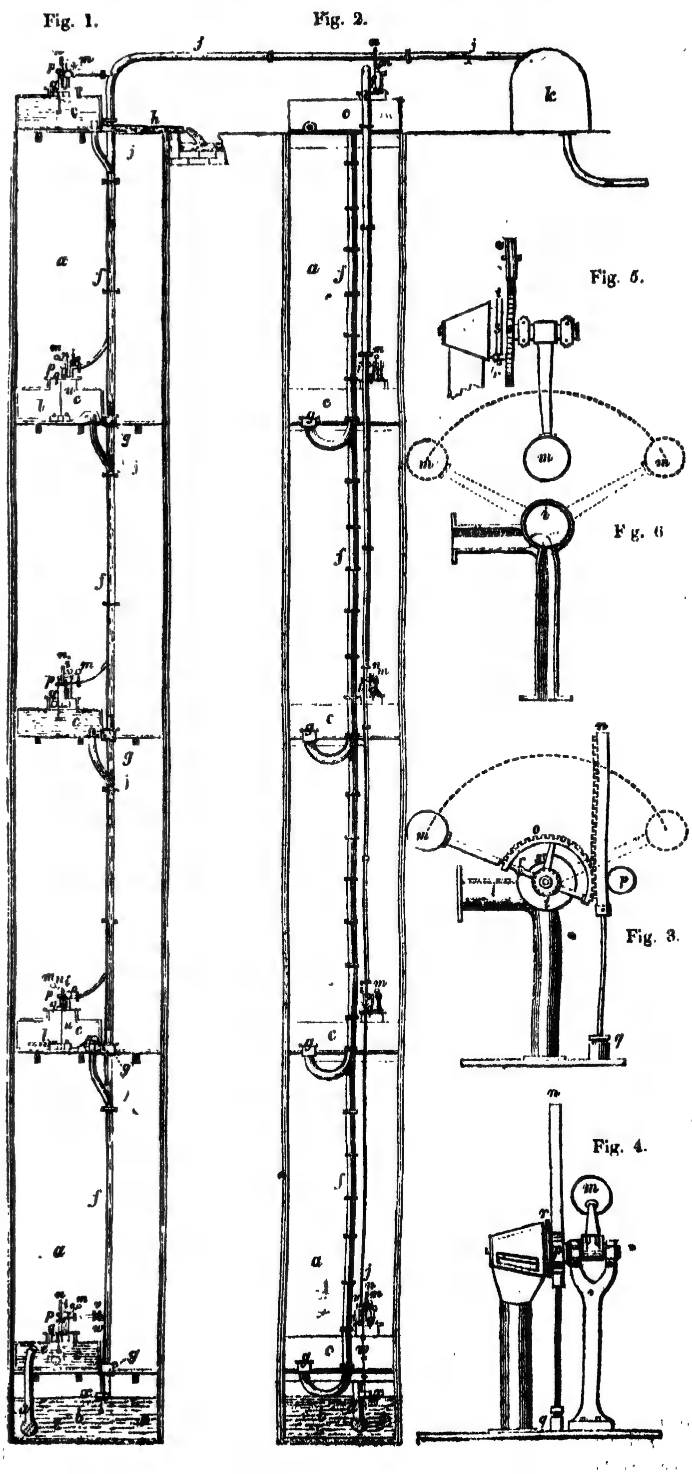
To all to whom these presents shall come, &c. &c.—Now know ye, that in compliance with the said proviso, I, the said John Hague, do hereby declare that the nature of my said invention, and the manner in which the same is to be performed, are fully described and ascertained, in and by the drawings hereunto annexed, and the following description thereof (that is to say):—

DESCRIPTION OF THE DRAWING.

In the said drawing,

Fig. 1, is a vertical section of a pit or shaft of a mine, with my machinery affixed therein; and,

Fig. 2, an end view and section of the same apparatus. The letters of reference indicating the similar parts in both figures. A A, represent the pit or shaft. B, the water accumulated at the bottom of the shaft. C C C C C, close or air-tight vessels, tanks, or cisterns; these may be placed above each other at any distance under the atmospheric pressure, and may be made of any convenient shape or form suitable to the purposes required; they may also be made of cast-iron, or wrought iron, or of copper, wood, or any other fit and proper materials, which may be best calculated for the purpose, but I prefer cast-iron. D, is a metal pipe or strainer, which is also termed a suction-pipe or wind-bore, being perforated all over its lower part with holes to admit the water, but to prevent the passage of large bodies into the pipe. On the end of this pipe, D, is placed a valve, E, opening so as to suffer the water to flow into the tank or cistern, but also closing when the cistern is full, to prevent the return of the water. F F F F, are four pipes or rising-mains, the lower end of each being connected with a valve-box, G G G G, placed at the bottoms of the tanks or cisterns; their upper ends passing through the bottoms of the cisterns above them, and rising a little above the said bottoms. The valves in the boxes, G G G G, open forwards to allow the water to ascend through the pipes, F F F F, but close to prevent it from returning into the tanks or cisterns. From the uppermost tank or cistern, a spout, H, with a valve at its end opening outwardly, proceeds to discharge the water so raised to the surface: I I I I I, fig. 1, represent five three-way cocks and their appendages. These cocks are mounted in branch-pipes, which proceed from a main exhausting or vacuum-pipe, J J J J, which is connected with an air-



vessel, or receiver, K. This main exhausting-pipe is better seen, at J J, in fig. 2. The conical plugs of these three-way cocks are put into motion, in the following manner:—L L L L L, fig. 1, are five hollow copper boxes or floats of sufficient buoyancy to raise the balls of the tumblers, M M M M M, from their state of rest past their centre of gravity, and as shown on a larger scale in fig. 3, by the dotted lines. These floats are caused to slide freely upon metal rods, which are passed through holes formed in the centres of the floats. At the lower ends of these rods are formed stops, for the floats to rest upon when the water in the tanks or cisterns is discharged. At the upper ends of these rods are affixed toothed racks, such as that shown on a larger scale, at N, in fig. 3. These racks act in toothed sectors, similar to that shown at O, in fig. 3, and are kept in geer by the guide-rollers, P, at their backs. The rods pass through stuffing-boxes, mounted upon the tops of the cisterns, and as shown, at Q, in figs. 3 and 4. The tumblers, M M M M M, are each mounted upon a separate axis, turning in bearings, mounted upon standards or pillars, and as shown more clearly in fig. 4, upon each axis is also affixed the toothed sector, O, as is shown in fig. 3. Upon one of the arms of this sector, O, is affixed a pin, R, which projects within a circular gap, S, in the plate or flanch, T, affixed upon the conical plug of the cock, I, as shown in fig. 3. At each end of the gap, S, are stops, against which the pin, R, falls, when the tumbler, M, has passed its centre of gravity. Besides the stops at the bottoms of the rods, upon which the floats rest, there are also others affixed at a proper distance above, as shown at U U, in fig. 1. When the water is rising in the tanks or cisterns, the floats rise with it, and acting against the stops, U U, carry the rods upwards with them, and also the toothed racks at their upper ends, which, acting in the toothed sectors, O O, cause the tumblers, M M, to pass their centres of gravity, and fall against one of the stops in the gap, S, and turn the plug, I, of the cock, so as to shut off the vacuum and open the passage to the atmosphere. When the water is discharged from the tanks, the floats by their weight, and being lodged upon the stops at the lower ends of the rods, cause the tumblers to again act in the reverse way, and re-open the cocks, so as to shut off the communication with the atmosphere, and open the passage to the main vacuum-pipe, and as shown at fig. 6.

Fig. 3, is a front view of the cock and appendages.

Fig. 4, a side view of the same.

Fig. 5, a top view thereof, showing the tumbler by its pin or stud, R, acting upon the plug of the cock; and,

Fig. 6, is a section through the barrel and plug of the cock and the vacuum pipe shown upon a larger scale. The air-vessel or receiver, K, is connected or united with an air-pump or pumps, which is or are worked either by steam, water, wind, animal, or other power, or hoist mover. This receiver, K, may be placed at any convenient distance from the mouth of the pit or shaft, and be connected with the vacuum-pipe, J J, by extending that pipe accordingly. Or it may also be made to connect with several vacuum-pipes by similar means. At the lowest tank or cistern, C, of fig. 1, V, is a cock mounted in the branch-pipe, leading from the cock, I, to the main vacuum pipe, J. To a lever mounted upon the plug of the cock, V, a rod, W, is affixed at its further end. This rod descends through two guides affixed on the outside of the tank, C; it has a stop at its lower end, and another at a proper distance above it; upon this rod and between the stops a hollow copper float, X, is mounted, which can slide freely up and down between the two stops. This float lies upon the surface of the water in the pit or shaft, rising and falling with it. When the water gets so low as to allow the float to rest upon the stop at the bottom of the rod, the weight of the float shuts the cock, V, and prevents the suction-pipe, or wind-bore, D, from drawing air. When the water in the pit or shaft accumulates it raises the float, X, until it acts against the upper stop on the rod which re-opens the cock, and puts the machinery again into action, and which continues until the water again falls too low as above-mentioned. In case of a steam-engine being employed as a first moving power, an inverted syphon, filled with mercury, may be connected on one side with the main vacuum-pipe, leading from the air-pump, and have a float resting in the mercury in the other leg from which a rod may proceed; connected with a lever, mounted upon the axis of a throttle-valve placed in the pipe, which brings the steam from the boiler to the engine, and thus, by regulating the supply of steam, retards or accelerates the motion of the steam-engine. Although the pit or shaft may be miles distant from the steam-engine, yet the float, X, in the water at the bottom of the pit, becomes the regulator of the motion of the steam-engine. In case of having to raise water from excavations, holds of ships or vessels, or where the depth is not so great as the atmospheric pressure, one lift will be found sufficient, and the air-pump may be frequently worked even by hand, or by the power of horses. To apply my said invention to give motion to certain machinery, such, for instance, as whimsies, for raising coals, or ores, or other substances from pits or shafts, and also for actuating stamping mills, crushing or grinding mills, cotton or woollen machinery, gunpowder mills, towing of canal boats, locomotive carriages on common and rail-roads, ploughs, thrashing machines, rolling-mills for metal, and other substances, paper-mills, turning and boring lathes, blowing-engines, and saw-mills, I cause the vacuum to act upon one or both sides of the pistons working in cylinders, after the manner of steam-engines, in the same manner as described in a patent formerly granted to me, for working cranes and tilt hammers, or forge-hammers, and which, therefore, need not be more particularly described here. I do not mean, or intend, hereby to claim, as my invention, any particular forms or arrangements of machinery, nor any of the parts herein shown and described, which may have already been used, but only in connexion in the manner herein shown and described. But I do hereby claim as my invention, the raising of water without its entering the working-barrels of pumps. I do not mean, or intend, hereby to confine or limit myself to the employment of any particular material or materials, in the construction of the different parts of the apparatus, but to employ any which are fit and proper for the purpose.—In witness whereof, &c.

Enrolled November 9, 1836.

[The general arrangements of this invention are very similar to an apparatus described in "Gregory's Mechanics," page 210, vol. ii., for raising water to a great height for irrigating land, in a situation having the advantage of a small fall of water. It is, in fact, Hero's fountain reversed. There is no doubt it would answer the purpose, and in some situations would be very valuable, where a central engine might drain several pits, situated in difficult situations, as the pipes might be carried through the workings of a mine, where pump rods could not be passed, excepting at great expense. Last, and not least, the air entering the boxes as the water is discharged, may be the foul air of the mine, and thus ventilation and draining may be carried on by one operation, and at an expense due only to the latter.]—EDITOR.

ARCHITECTURAL PRACTICE.

SIR,—A short time ago we were induced to purchase your journal at the solicitation of a friend, who recommended the work, as being the only medium for acquiring correct architectural information. It is unnecessary to state more, except, that after carefully examining several numbers, we were struck with the *fact*, that many important communications were passed unnoticed by the majority of your readers; for instance, in your number for *December* last, we find an article upon *Competition Estimates*, which is a subject of interest not only to the architect and builder, but also to the public at large. This letter, we believe, has never been commented upon, nor any *practical hints thrown out*, by your numerous correspondents. Under the impression, then, that the following *system* may be deemed worthy of consideration, or at all events call forth the talents of those who, from longer practical experience, are capable of *judging* of its working, we gladly take the opportunity of briefly stating our method of conducting contracts in Liverpool.

In the first place, we are careful that our *working drawings and details* are complete and perfect, so that it is unnecessary to furnish *more* during the execution of the building. We then print the specification, after which the whole matter is given into the hands of an acknowledged *measurer*, who takes out the *quantities* upon his *own* responsibility. We then *advertise* in the usual way, except that we inform the parties tendering, that printed copies of the quantities may be obtained from the surveyor, without any *charge*, in the first instance; but, should the builder be successful, he pays *one half* the fees of measuring, and the proprietors or committee the *other half*. This we find to save a considerable time in the first place; and, secondly, the printed *schedule* is filled up in *detail* by the contractor, with the prices of each *article per foot, lineal, superficial, &c. &c.* This list is deposited *with us*, and becomes the standard for all *extras* or *deductions*, and, we must say, is the best arbitrator we have yet met with. *Should* it happen that the proprietors make extensive alterations, we then employ the surveyor to measure the extras, and we ourselves fix the price from the *list* above-mentioned. It is proper to state, that we are not aware of this *plan* being adopted by any other member of the profession in this place; indeed, we are sorry to acknowledge, that in almost every instance the architect has the whole business of measuring, calculating, &c. This you will be aware is a most ruinous proceeding to all parties concerned, besides placing the architect in a *subordinate* situation, and without that independence of action which is so necessary in a professional man. We hope and trust, however, that in London you have a better state of things, or, in truth, your correspondent "*J. J.*" may affirm, that contract work is never so well done as it ought to be. We intend shortly to forward you a short account of some of our new buildings in this place, should you think it worth while. We remain, in great haste, yours, &c.

Liverpool, April, 1838. C. & H.

[Our correspondents' practice nearly agrees with that which is adopted by the architects in London, excepting that instead of one surveyor being appointed, there are two nominated, for the purpose of taking off the quantities; one by the architect, and the other by a majority of the builders who intend to send in tenders. The two surveyors take off the quantities together, and check each other as they proceed, in the dimensions, abstract, and bill of quantities. The successful party, whose tender is accepted, has to pay the surveyors their charges, which are generally added to the amount of tender by all parties alike, the surveyors previously informing them of the amount.

We feel obliged by our correspondents' offer, and shall be most happy to hear from them again.]—EDITOR.

DRY ROT IN TIMBER.

Extracts from the Fifth and Concluding Lecture on the Qualities of Timber, delivered before the Royal Institute of British Architects, by ROBERT DICKSON, M.D., F.L.S., *on Monday, March* 26, 1838. EARL DE GREY, President, in the Chair.

THE most effectual means of preserving timber from decay, is a subject of vast interest and importance to the engineer and architect. It will be admitted by all, whatever they may think of the probable success of Mr. Kyan's

mode of seasoning timber, and insuring it particularly against the ravages of dry-rot, that the operations of the Company engaged in working out his plan are affording us, on a grand scale, that experience which must be the ultimate test of the value of such an invention. It is not a short series of years that can convince the world of the complete success of his process, in eradicating an evil, which itself comes on silently and slowly. His earliest experiments are perhaps not sufficiently widely known to satisfy all; but now the operations are carried on so extensively, it is so generally known that various great public works are executing with timber prepared under his patent, that all have the means of judging for themselves of the efficacy of the plan. Time alone will show what is the value of the invention. In the meanwhile Mr. Kyan's method receives every encouragement in the countenance of the numerous eminent professional men and great public companies who are adopting the process; and the public may be greatly assisted in forming their judgment, and disabused of some prejudices on the subject, by the interesting and useful lecture from which we proceed to give extracts. Though one of a series, it is complete in itself; it has for its subject *the causes of decay in timber, and on the most effectual means of preventing it.*

"The utility of timber, when employed in the construction of edifices and other arts of life, is greatly lessened by its perishable nature. In all cases where wood is wished to be durable, it must be submitted to processes which have hitherto been tedious, and attended with the loss of capital, thus rendered inactive during the years which were required for their completion. These processes are termed seasoning and drying; which are accomplished either by the natural powers of the air, to take up and carry off superfluous moisture from any body which will readily part with it; or by immersing the timber in water, which dissolves out the mucous and other viscid soluble principles which have a tendency to retain much of the moisture, and thus permit the more speedy evaporation of the watery part, upon the removal of the timber to a dry atmosphere, where there is a free circulation of air, by which the process is expedited; or, to render it still more expeditious, recourse is had to boiling or steaming, the higher temperature rendering the solution of many of the principles more easy.

Of all these means, steaming appears to be that which facilitates the process to the greatest degree, 'the seasoning going on more rapidly after the piece is steamed than when boiled.'—*Barlow on the Strength of Timber*, p. 14. By all of them a loss of weight is occasioned. Steaming, or boiling, 'impairs the strength and elasticity of timber;' but Mr. Tredgold thinks 'it gives another property, which for some purposes is still more desirable than strength; for boiled or steamed timber shrinks less, and stands better than that which is naturally seasoned.'—*Carpentry*, p. 157. The most expeditious of these processes still requires months for its completion, and the wood is generally squared before even commencing them, by which a large quantity of timber is rendered useless for the purposes of construction.

The object of all of them is to counteract, or, more properly speaking, to postpone the operation of those causes of decay which are inherent in wood and all organized bodies. They effect this, however, in the majority of cases, in a very limited and inadequate degree; for still decay occurs, and succeeds in reducing these structures to dust and ashes. Decay may occur while the tree is yet standing, and is indicated by the death of the main-top, which is generally the result of the infiltration of water into the interior of the tree, by natural cracks or accidental openings, which gradually affects the internal part of the wood, and occasions its decomposition. This extends from the heart outwards; the external or young parts resisting for a longer time—and hence those shells of ancient trees which we frequently meet with. The progress of this kind of decay undoubtedly continues after the tree is cut down, and even fashioned, and applied to use: the order of march, however, is still the same; the layers, or circles, successively becoming decomposed, according as they are near the centre. The whole process is slow in its operation, often requiring forty or fifty years to destroy a beam of moderate dimensions:—though this kind of decay is important, it is not necessary to speak further of it, as there exists so simple and effectual a remedy, viz., cutting down the tree before it shall have passed its zenith.

The other kinds of decay to which timber is liable, are termed the common rot and the dry-rot. 'The former,' Sir John Barrow considers 'to be occasioned by alternate exposure to the vicissitudes of the weather—to moisture and dryness, and to heat and cold—hence, frequent at the point where a pile is between wind and water, or where a beam enters a wall: in the latter case, the progress is from without inwards.'—*Supplement to Ency. Brit.*, Dry Rot. As the causes here are extrinsic, protecting the wood against them is often sufficient; for this purpose, painting, coating with tar, &c., are had recourse to.

Widely different is the case with the dry-rot, the causes of which are inherent in the timber, and only require the concurrence of a few external conditions to come into action. It has been, with propriety, proposed to designate this malady sap-rot, since the elements of it chiefly abound in the outer layers of wood, and, when its direful action has begun, proceeding from the more external to the internal layers, the entire structure, however, soon becoming involved. The reasons of its commencing in the sap-wood are to be found in an attentive consideration of the nature of that part of the vegetable fabric."

Dr. Dickson next proceeded to describe the growth of timber, its constituent parts, and the cause of their decay by fermentation.

"The sap-wood is the part in which the decomposing operations commence; and hence the propriety of the term sap-rot. With regard to the share which each of the destructive agents has in the whole series of actions, it is enough to state that the fermentation excited by the albumen is the primary and essential, the agency of insects and fungi being only accessory. Insects attack vegetable structures, both living and dead, chiefly for the saccharine or mucilaginous principles which they contain, and aggravate the evil, principally by hollowing out the substance, and permitting the access of air and moisture; but the part performed by fungi is more obscure, and hence numerous erroneous notions exist respecting them. Some have thought that they were examples of equivocal generation—an opinion which receives no countenance from any one who has carefully studied their nature, or the mode of their production. The minuteness of their reproductive matter allows them to escape observation when scattered; but this is always prepared in definite and fixed parts of the structure of those already existing, as much so as that of the seed of a rose or of an apple; but their number surpasses that probably of any other vegetables,—while their sporidia, or reproductive particles, can retain the power of vegetating as long probably as any seeds.

The albumen of the wood must be in a fluid state, or capable of becoming so, before it can enter the tissues of the fungi; for they cannot, any more than other vegetables, by their roots, take up even the proper materials of their food, unless it be in a state of solution. The germs of the fungi are roused into activity by the heat accompanying the fermentation of the albumen, and other fermentable principles, just as mushroom spawn is developed by the fermentation of the dung, &c., of a mushroom bed.

The abundance of fungi in autumn, while the earth and air are still warm and much vegetable matter is going to decay, shows how far heat aids in their development.

It appears, therefore, that the whole theory of any successful plan for the prevention of the dry-rot must resolve itself into the *solidifying or coagulation* of albumen. This will at once prevent the commencement of the fermentation, which decomposes the original structures of the wood, and the development of fungi; which are neither the cause of dry-rot, as held by some, nor the effect, according to others, but the incidental accompaniment, when their germs happen to be present in the tissues of the wood.

Now, this is precisely what is effected by the method of Mr. Kyan, and it matters not whether he invented it or merely extended a plan in use before or suggested by others; for, though it was suggested, both by Sir Humphry Davy and Mr. Chapman, before he brought his publicly forward, yet he who by his energy and perseverance brings the method into use, deserves to be regarded as the inventor."

The lecturer then described the method adopted by the ancient Egyptians for the preservation from decay of the dead bodies of their deceased friends. The agent employed by them has been discovered to be *creosote*, which is now extensively employed for the preservation of animal structures for anatomical purposes, as it coagulates the albumen. Anatomists have long employed corrosive sublimate to preserve their preparations, even the most putrescible.

"The collateral evidence of the utility of coagulating albumen, as a means of ensuring the preservation of the substance, seems ample enough.

We must now inquire how far this method confers durability upon timber for practical purposes. We know the extremely long period which some timber will last; but we also know how liable much of it is to decay; and, as no one can be sure that any given piece of timber which he intends to use possesses the qualities requisite for durability, it seems desirable to have recourse to some means which will confer an equal degree of durability upon all the timber employed in the construction of an edifice. We are, I think, warranted in anticipating that such will be the result of Mr. Kyan's plan; which effects the solidification of the albumen, more particularly of the sap-wood; thus preventing it being liable to fermentation, or capable of being dissolved to furnish a pabulum to fungi.

As the depth to which Kyan's solution penetrates has been made the subject of careful investigation, by Professor Faraday and others, I refer, on this head, to their evidence; and rather touch upon some other points."

It appears from experiments which have been made to ascertain the comparative strength of wood prepared by Mr. Kyan's process, and unprepared wood, that the preparation makes no change in its strength.

Dr. Dickson made some remarks, to show that the small quantity of mercury contained in the wood was not injurious to the health of the inhabitants of houses, or ships constructed with prepared timber.

"Holding the question of the preventive power of Kyan's plan to be settled in the affirmative, as far as the dry-rot, in the strictest sense of the term, is concerned, it may be proper to adduce some proof of its preservative effects against insects and fungi. Mr. Curtis, the distinguished author of the 'British Entomology,' has informed me, that since *palings of prepared wood* have been used in the Regent's-park, he can no longer find those insects which formerly abounded there. Farther, the Rev. Miles Berkeley, author of that part of 'Smith's English Flora' which treats of fungi, and who publishes 'Fasciculi of Dried Fungi,' in illustration of that volume, having been annoyed by a fungus called Thelephora puteana springing up in a cupboard, which it rendered constantly damp, he applied a solution of corrosive sublimate to the woodwork; and so effectual did the application prove, that he cannot now procure a single specimen of that fungus, though it would be invaluable to him for the completion of his work.

Having the evidence of so many different individuals in favour of this plan, none of whom have any pecuniary interest in its being adopted, we must either question their competency to judge of its merits, or admit its validity; since we may well ask—

'Or how, or why
'Should all conspire to cheat us with a lie?'"

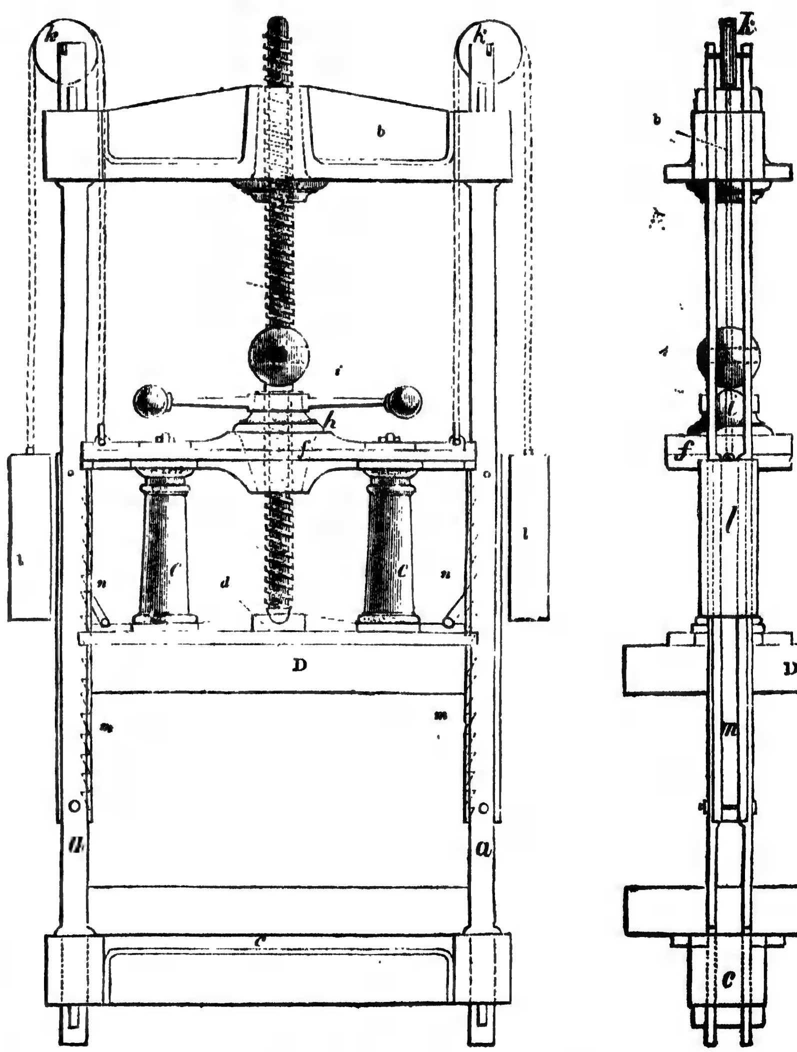
The lecturer concluded by reading the following certificate from Mr. Beazley, the architect:—

"March 24th, 1838.

"Sir,—At the commencement of the year 1836, I surveyed and accurately examined the posts and paling in the Regent's Park, for the purpose of ascertaining the comparative states of those timbers which had been prepared by Kyan's Patent and those which had not been submitted to the process of solution. In my report of that period, I stated that indications of decay were already perceptible in most of the unprepared timbers, both at the bottom of the posts, and in those arris edges and ends of paling which were placed in or had come at all in contact with the earth, while those timbers which were marked as having passed through the solution were quite free from any such symptoms. I now beg leave to state that I have this day, after a lapse of two years and a quarter from my previous survey, agaain ccurately examined several of the same posts and paling, digging away the earth from the foundations for that purpose; and find that the symptoms of decay, mentioned in my preceding report as having commenced in the unprepared timber, have so considerably increased, as to have rendered the bottom of the posts completely rotten, to a depth of from one to two inches, and that, in several instances, fungi have been the consequences of the decay; while I find the prepared timbers which are in the earth sound and in the same state, with the exception of mere discolouration upon the surface, probably arising from the damp state of the earth at the time of its removal. As a farther proof of the difference existing between the unprepared and the prepared timber, we could cut, with the greatest ease, large pieces from the former with the spade, without using any force, while it required great exertion to chip off very small pieces from the latter. I have the honour to be, &c.

To Wm. Morgan, Esq. SAMUEL BEAZLEY, Architect."

CURTIS'S SCREW PRESS.



The important character of this press is, that in the first instance it compresses the goods subject to its actionin a rapid manner, and afterwards by a slower and more intense pressure. In the common screw, an intense power can only be obtained by either a very fine screw, or a very long lever; but in this case a power, however great, can be obtained by a screw, however coarse, and a lever, however short; it is only necessary that then, to procure an infinitely high power, the difference between the two threads of the screw should be infinitely small, although the pitch of the screws may be individually, however, coarse.

The principle upon which the screw acts is similar to Hunter's screw, described in most elementary books on mechanics; but for all practical purposes that screw is useless, and totally different to mine. It will be seen, upon reference to the plate, that the screw is double: the upper part, working in the head of the press *b*, is, for example, three quarters of an inch pitch; and the lower part, working in the loose nut *h*, is five-eighths of an inch; the difference therefore is one-eighth of an inch; so that when the screws work in concert, it is equivalent to a single screw of one-eighth pitch.

The mode of operation is as follows: When the goods are placed in the press, the screw is brought down, and the toe of the screw enters the step *d*, fixed upon the follower D; it then acts by the upper screw alone, and is the same in this case as any other screw press; but when the goods are compressed as far as the power of the workman can by this screw compress them, the palls *n n*, connected with the upper part of the follower *f*, are thrown into the ratchet sides *m m*, fixed in the sides *a a* of the press; these ratchets hold down the follower, whilst the screw is screwed back as far as it can be towards the head of the press *b*, then the moveable nut *h* is brought down upon the head *f* of the follower, and the screw again screwed down upon the goods; but now the two screws act together, and the space through which the follower moves is one-eighth of an inch at each revolution of the screw. When the screw has reached the step *d*, the palls are again thrown into the ratchets, and the screw drawn back as before, so that by this means the follower can be advanced a distance by the higher power of the screws equal to the screws' length; *c*, is the base of the press; *e*, the columns supporting the head of the follower; *i*, the handle and balls, connected with the loose box *h*; *k*, wheels, over which pass the chains connecting the counter-balance weights *l l*, with the follower D. A press of 100 tons' power may be seen at Messrs. Rennies; it has been proved in various ways; and from the circumstance of its extreme simplicity, and not *giving* under the pressure, is, in every sense of the word, superior to the hydraulic press. For the purposes of the manufacturer, it is decidedly to be preferred; its cost is less than the hydraulic press, and it is liable to no accidents; and for the colonies, and the packing of cotton, &c., its use will be invaluable.

W. J. CURTIS.

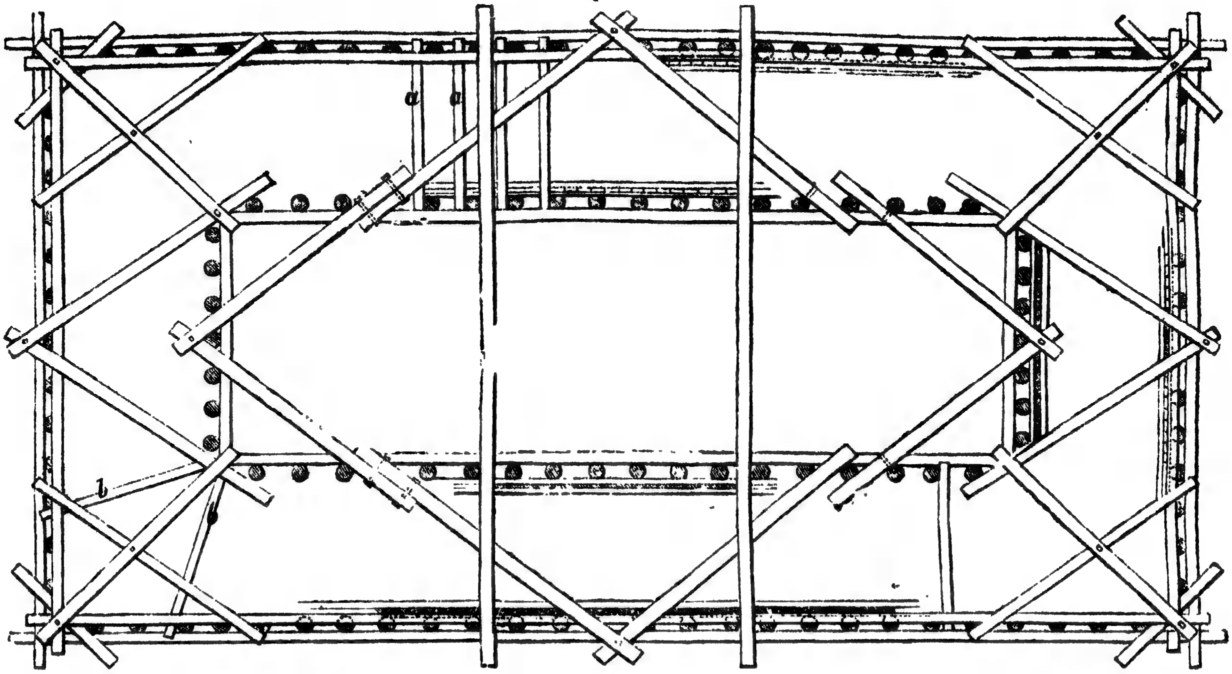
POTOMAC AQUEDUCT.

(Continued from page 160.)

Fig. 6.



Coffer Dam, Pier No. 1.

June 14th, the oak piles of dam No. 2, being all driven, preparations were made for building one for the pier (No. 1.) next the Virginia shore, upon the site that had been occupied by the circular coffer-dam of Messrs. Martineau and Stewart; this dam was upon the same plan as that of the dam for pier No. 2.

It would have been well if we could have waited to profit by the experience to be gained in employing No. 2, but it was then believed that two piers might be built within the year, and we had to proceed with both. Our experience, however, had taught us to guard more effectually than heretofore, against the expansion of the clay puddling, which tended to force the outer and inner rows of piles apart. Ties were therefore placed at every oak pile, and they were notched on to the string pieces, and were rag-bolted to the stringers and oak piles.

Large timbers (14 inches square) were laid from the centre of the outer row of the sides of the dam, crossing the corners to the centre of the outer row of each end, and they were notched on, and bolted to every timber they crossed; these ends, too, were made to cross, and were halved into each other, and were secured by a bolt. Two long tie pieces were then placed entirely across the dam, dividing it into three equal parts, and notched and well secured.

The up-stream ends of this dam were left square, great difficulty having been experienced in cutting off the corners of the other dam, and the angles were secured by a second set of stringers placed upon the tie pieces of the outer and inner rows of piles, and bolted to the oak piles, they passed and were halved into each other at the corners of the dam; these stringers were continued entirely around the dam, and a piece was also placed at each corner, to connect the exterior and interior pile of the angles, as in figure 6.

Pumping and Excavating Coffer Dam No. 2.

The puddling of dam No. 2 was then brought up to a level with the tie pieces, and two pumps were placed in the down stream end of it, they were octagonal shaped, and were shortened to conform to the then depth of water, and were placed in the dam for experiment; they were found, however, to be quite sufficient to discharge the water as low down as the original surface of the mud.

On the 2nd of September a trial was made of the pumps, which did not prove to be very satisfactory, owing to the stretching of the ropes and the breaking of the straps, &c. &c. (leather straps being first used for the buckets, for which chains were ultimately substituted). On the 3rd of September another trial of the pumps was made, more successful than the first, although the machinery still worked imperfectly.

The pumps were worked by ropes passing over grooved sheaves eighteen inches in diameter, attached to a drum four feet in diameter, on the steam-engine; the drum, by a reciprocating motion, caused one bucket to rise while the other descended. The length of the stroke of each pump was six feet, and the engine, at first, made twelve strokes per minute, and lowered the water in the dam at the rate of two feet per hour. The speed of the engine was then increased to fifteen strokes per minute, and was continued at that speed for one and a half hours, in which time the water was lowered one foot ten inches more.

The dam being now in some danger from the pressure from without, the pumping was discontinued, and additional shores were placed against the stringers, and preparations were made for placing a second tier of shores eight feet below high-water mark.

On the 6th, after some further alterations, and the ropes being well stretched, another trial of the pumps was made, and in fifty-six minutes time the water was lowered three feet, but still the discharge was only 4.1 cubic feet per stroke of six feet, while the capacity of such a stroke was in fact 8.2 cubic feet, a diminution of one-half, being attributable to the leakage of the pumps, and the imperfect working of the buckets. On the 8th of the month, the second tier of shores being prepared, the water was lowered two feet in one hour and eight minutes, so as to admit of their being placed, and they were placed on that day, the carpenters working until ten o'clock at night.

On the 9th, the water was lowered two feet six inches in forty minutes, and it being now nine feet six inches below the high-water level, the weight of the puddling was such as to cause the sheet-piles to spring inwards, short pieces of timber were therefore wedged in between the oak and sheet-piles, extending from oak pile to oak pile to support the sheeting.

On the 10th, the water was reduced in depth two feet in forty-five minutes, and on the 11th, four feet in fifty minutes, the pumps discharging 6.87 cubic feet per stroke, working at fourteen strokes per minute; the leakage of the dam at this time was observed to be one inch per hour.

So frequently were accidents happening to the machinery and pump gearing, that the time of pumping in each day rarely exceeded the time above noted.

The dam being now entirely emptied of water, a third tier of shores were placed this day at the surface of the mud.

The excavating machine was put into the dam. This machine consisted of an endless chain of buckets, working vertically over and under square drums of cast-iron, fixed at top and bottom in a frame of four upright pieces of timber forty-five feet long, this frame was suspended on a moveable axis, resting upon a carriage which was moveable on a railway crosswise of the dam; and this railway was upon a carriage likewise moveable upon a railway lengthwise of the dam; the breadth of the sides of the square drums corresponded with the length of the links of the chain. See figs. 1 and 2, p. 147.

Upon the axle of the upper drum, a cam and near it an open box or hod was fixed (see figure 10) to receive from the buckets, and discharge into an inclined trough, the matter brought up by the machine. See fig. 2, p. 147.

This contrivance worked well, and preserved a constant communication between the buckets and the scows which were stationed under the lower end of the trough and along side of the dam.

The excavating apparatus was worked by an endless rope passing around a drum on the steam-engine scow, a bevel gear (fixed upon the carriage which moved lengthwise of the dam) changed the direction of motion by another endless rope passing around a drum upon the machine itself.

This machine being in readiness, a trial was made of it on the 2nd of Oct., which was not very successful, for it was found to be a very difficult matter to give to the endless chain its proper degree of tension; it broke on the first trial from the great resistance it met with in dredging.

On the 3d and 4th it was tried again, but it still worked indifferently, and it was found to be extremely difficult to be moved upon the railways, owing to its very great weight, and especially when it became clogged with mud.

To move it from space to space between the shores, where only it could operate, it was necessary to lift it over the shores, and this was attended with very great delay.

The intention of using it as an excavator was therefore abandoned, and it was fixed within a few feet of the pumps, and used as an elevator, labourers with shovels being stationed in the dam to fill its buckets. As an elevator it proved to be useful, although it was yet not without its inconvenience, the men were sometimes unwilling to work under it, as they often were exposed to the falling mud and water.

In addition to this machine, a windlass was erected across the dam near its upper end; it was also worked by the steam engine, and was capable of raising four buckets at once, each containing 4.6 cubic feet. The horse pile drivers were stationed at the centre of the dam, and were also used for hoisting out mud. See figures 1 and 2, p. 147.

By these means six feet depth of mud was removed by the 22nd of October, notwithstanding the frequent interruptions from the machinery getting out of order.

At this period it was discovered that several oak piles on the south side of the dam were broken, and that the great pressure had caused the braces at the end to crack; this created great alarm among the labourers below. Immediate steps were taken to secure the work by doubling the number of shores at the original surface of the mud, and by placing another tier (4th) at its then surface; but before this could be fully accomplished, viz., on the 30th, a leak occurred in the north-east corner of the dam, which soon filled it. This leak was caused by the great weight of the column of water on the outside forcing the mud from beneath the puddling into the dam under the foot of the "montant" piles, which, as before remarked, were not driven to the rock. The puddling soon after settled down and stopped the leak, and the vacancy at top was filled up.

The following day the pumps were at work again, and had lowered the water eight feet, when the crank wheel of the engine broke, principally, no doubt, owing to the smallness (18 diam.) of the sheaves over which the pump ropes moved, too great a strain being thus brought upon it; these sheaves were taken out, and others of three feet diameter were substituted. The crank wheel was replaced by a new one, November 1st, and on the 2nd all the water was pumped out of the dam, and the carpenters resumed the business of shoring.

The dam was not now so tight as it had been heretofore; several small streams of water came in around the down-stream end, notwithstanding which, one pump was found to be sufficient to keep down the leakage, and enabled the carpenters to work with comfort.

During the night of the 3rd, while the pumps were at work, a large leak opened at the south-east corner, from the cause heretofore mentioned, and filled the dam, no workmen being in it at the time; the leak was not discovered soon enough to stop the pumping before the sand had accumulated above the heel of the pumps. The increased strain thus brought upon the pump ropes, broke the crank shaft, and this derangement of the engine caused the breaking of the flange of the fly-wheel. On discovering the condition of the work, the pumps were hoisted out of the dam and cleared of sand; the repairs of the engine were immediately commenced, and an alteration was made in the pumps by cutting holes in them for the discharge of the water a few inches above the level of the dam; heretofore it had been discharged at their full height.

On the 5th the pumping was again resumed, and 17 feet 4 inches depth of water was discharged by two pumps in 4 hours 32 minutes working time, or at the rate of 3 feet 10 inches per hour.

The puddling which had settled down five feet was replaced, and this increased weight of clay caused the stringers of the outer row of piles to break, and the wall of the dam of course to spread a little.

It was now that the long ties, heretofore described as extending entirely across the dam, were put in.

The weather having by this time become very cold, and indicating an early winter, it was thought prudent to make preparations for protecting the dams against the floating ice which the freshets might carry against them. Accordingly an ice breaker was commenced a short distance in advance of each of the dams.

Although the intention of emptying dam No. 2, and commencing the masonry, if possible, this year, was by no means abandoned; on the contrary it was resolved to prosecute the work night and day, and on the 8th the excavation was resumed; some delay was caused, however, by the last incursion of sand which had accumulated about the pumps, so that the water could not be entirely pumped out, and it had also buried up the lower buckets of the mud machine; these were soon relieved, however, and the machine was actively at work until the afternoon of the 10th, when the crank shaft of the engine working the pumps was again broken; the other engine working the mud machine was kept at work raising water only, and it was found sufficient to keep the leakage under, so that the carpenters could work below.

The crank shaft of the broken engine was replaced that night, and a gang of labourers were employed also during the night in removing the sand from around the pumps. On the 11th the pumps were lowered, and the dam was entirely drained of water. The windlasses for raising mud at the upper end of the dam were again put, and continued in active operation, although frequent interruptions were caused by the breaking of the pump ropes.

As the height to which the water had to be raised increased, these ropes were found to be too weak, and their size was increased to six inches.

At this time, W. M. C. Fairfax, Esq., the engineer of the Alexandria Canal Company, who had been heretofore associated with me on the work, acquainted me with his intention to retire from the service of the company; a resolution which I learned with much regret, as he was a well-informed and very efficient engineer, and our intercourse had been always characterized by much harmony of opinion and feeling.

The excavation went on very actively and without interruption until the 15th, when the leak sprang again in the south-east corner; the water rushed in very copiously till it reached the lower tier of shores, when the puddling on the south side settled down two feet below the tie pieces, for two-thirds of the whole length of the dam, and the leak then diminished.

The weather being at this time very stormy and cold, the labourers were very reluctant to work, and, in the afternoon, one-third of their number refused to return to it; those who did, were employed in replacing the puddling; but that night not a labourer could be induced to turn out.

The superintendents, carpenters, and blacksmiths, were therefore sent on the dam to hoist the pumps out of the sand, and at midnight one pump was at work.

The next morning, there being no abatement of the storm, the labourers still refused to work, and the mechanics were again sent in their stead to raise the other pump, and this was done during the day, and the dam was then drained as low as the last incursion of sand would permit.

One pump, which was sufficient to keep down the water, was kept at work during the night, in the hope that the weather on the ensuing morning would be more favourable; but the storm still continued, and snow having fallen previous to the rain, there could be no doubt but that there would soon be a freshet in the river. It was therefore thought prudent to secure every thing about the work, and as labourers could not be procured for that purpose, the mechanics again cheerfully undertook this duty also. The current already in the river being too strong to attempt the removal of the steam scows, scope was given to their fastenings, and they were allowed to swing under the lee of the dams.

The pile driver scows, the large crane scow, and some of the smaller scows, were moored under the lee of the causeway of the aqueduct; but after six hours' exposure to a pelting rain, which froze as it fell, and in the night too, we were forced to return to the shore, and leave the others to take their chance, secured to the dams as well as they then could be.

During the night, several of the scows were swept from their moorings and driven ashore, and, as had been foreseen, the freshet rose over the sunken puddling, and filled the dam.

Nov. 18th. The weather cleared off, but the labourers did not return to work at the usual hour; but during the day, a small force was raised and set to work to get off the scows that had been driven ashore. On the 19th, this force was increased, and employed in boating clay to replace the puddling which had sunk in the dam.

On the 20th, a large force of labourers was raised, and employed in boating clay; and at noon the repuddling was completed, and the pumps were in readiness for work.

The dam was pumped out during the night; but on the morning of the 21st, the leak in the north-east corner opened again, and spouted copiously for a few minutes; the puddling then settled one foot, and the leak ceased. The weight of the puddling on the south side caused the dam to spread a little more, and additional long ties were therefore placed across it.

The pumping was continued during the night of the 21st, until the segment wheel of the pump gearing broke; but it was soon replaced by the one from the other engine, and the pumping continued.

In the afternoon of the 22nd, the leak in the north-east corner increased, the dam filled, and the puddling settled* two feet.

I had been much disheartened by these frequent leaks and incursions of sand; but it had now become very apparent that the whole mass of mud and sand underneath the puddling would be washed into the dam, and that, on its being replaced by the clay puddling, the dam would become tight.

But notwithstanding this conviction, it was not very pleasant to recollect that the other dam (No. 1) was constructed upon precisely the same plan as this, and that consequently the same difficulties might be reasonably anticipated with respect to it. But I now felt quite convinced, that by perseverance all difficulties could be overcome, and the ultimate success of the work ensured. I was very much encouraged also by the confidence of the president and directors, and their advice to persevere.

Sunday, November 23rd, was very boisterous, and it was with great difficulty that clay could be boated to the dam, especially with so small a force as could be induced to attend; one pump was at work, and at four o'clock in the afternoon, the water was down to the lower tier of shores, when the crank shaft of the engine broke; during the night it was so stormy that it was impossible to keep lights to hang the crank wheel upon another shaft.

These frequent *fractures* of the machinery were attributed, and I think with reason, to the intensity of the frost.

On the 24th, the water in the dam had risen but twenty-two inches in fifteen

* At sunset the pumps were at work again, and the water was lowered very rapidly; but during the night, the dam again filled, and another settlement of the puddling took place.

hours, during which time the pumping had been suspended, the crank shaft was replaced, and the pumping was resumed, but the weather was so boisterous and cold that the labourers could not be persuaded to go into the dam. On the 25th, in the afternoon, four men were persuaded by the offer of high wages to go below and clear the sand from around the pumps, but working at night was entirely suspended, by the difficulty of procuring labourers.

On the 26th, the labouring force was increased to eight men, who were employed clearing away the sand from the pumps and in throwing it to a convenient place, to be raised by the machine. The force was increased gradually, and the excavation now progressed very well. On the 3rd of December, the rock beneath the mud was touched by one of the shovellers about the centre of the dam; at dark, when the labourers left off work, the dam was perfectly dry, it was examined all round and no appearance of a leak was discovered. At nine o'clock a noise was heard, of which no notice was taken by those who attended the steam-engines and pumps, but at one o'clock in the morning, the superintendent of pumping discovered that the dam was full of water, a leak having opened in the up-stream end, and that the puddling had settled down five feet. The next morning the whole force was employed in boating clay to renew the puddling, and the pumps were tried, but without effect; the tide ebbed and flowed in the dam. At two o'clock, P. M., the puddling was raised nearly to the tie pieces, and the pumps were tried again with better success than in the morning. The water was lowered six feet four inches in one hour and forty-five minutes; the pumping was continued during the night, and on the 5th, the dam was entirely free of water, and the windlasses at work hoisting out mud; this last incursion of sand and mud was comparatively small, it was all removed at noon; but whilst the labourers were at dinner, the leak opened again, and the dam filled; the puddling settled below the tie pieces, but it did not stop the leak; the pumps were tried at intervals throughout the night, but without effect, and the tide continued to ebb and flow in the dam until the 8th, when the puddling at length settled down, and the water was pumped out.

On the 9th, soundings were taken to determine the quantity of mud yet to be removed, and it was found to be 350 cubic yards, the surface of the rock very uneven.

The excavation progressed very well until noon the next day, when several leaks occurred at once on the south side, and the dam filled. On the 11th the puddling, which had sunk, was replaced, and the dam pumped out again.

The excavation was resumed, and all the sand that had been washed in under the "montant" piles was removed.

It was ascertained that this last incursion of sand came from the outside of the dam, as well as from underneath the puddling, and that the outer row of piles had settled down five inches, whence it plainly appears, that the outer as well as the inner row of piles ought to be driven to the rock.

The dam was now tight, and the excavation continued until the 19th, with occasional interruptions from the breaking of the machinery, which we attributed to the frost. On the 14th, the puddling on the south side settled three feet, but this caused no interruption to the work.

On the 15th, the river was covered with ice, the water in the supply-pipe of the engine was frozen, and the flanges of the steam-pipe broke. These were soon repaired, and, in the afternoon, the windlasses were at work. On the 17th, a large force was employed at the excavation, and both the machines and the windlasses were at work until noon, when the loss of steam occasioned by the break in the steam-pipe rendered the engine incapable of working, and the excavation was consequently suspended. While the engine was being repaired, another set of shores was put into the dam.

On the 19th, the repairs to the steam-engine were completed, and the windlasses at work; the rock, for several feet at the upper end of the dam, was entirely laid bare.

A small leak was observed on the south side, near the upper end, but it soon ceased. Orders were now given for a boat load of stone to be brought alongside of the dam, and other preparations to be made for commencing the masonry the next day. A small force of labourers were persuaded to remain through the night to wash off the rock, and have everything in readiness for the masons in the morning. But at 11 o'clock, the leak which had threatened us in the morning, burst in with great violence, and the dam was filled with water in twenty minutes' time; the puddling then sank down four feet.

On the 20th of December, the whole of the force was employed in boating clay to replace the puddling; the pumps were also tried, but without effect.

At 2 o'clock, P. M., the puddling was raised sufficiently high to keep out the tide. At ebb-tide the water remained at a higher level in the dam than in the river, consequently the leak was stopped.

The pumps were now started again, and at the expiration of one hour, the water was lowered 2 feet 11½ inches, and the pumping was ordered to be continued during the night; but at 10 o'clock the connecting-rod of the engine broke, and caused some delay.

On Sunday, December 21st, the water in the dam was lower than the lower tier of shores; but the segment wheel of the pump gearing breaking, and another leak having sprung on the north side, the dam filled again.

It had been in contemplation, and arrangements had been making for some time past, to alter the mode of pumping, by taking out the drums, and substituting a crank motion.

All the fixtures for this purpose being in readiness, that alteration was now made.

December 22nd, the puddling was replaced, and the tide shut out at low water, and the tide did not rise in the dam. But the alterations of the engine, and the consequent changes in the sheaves for the pump ropes were not completed until midnight of the 23rd, at which time the pumps were put in motion. The new crank worked very well, but the pumps were soon choked with sand, and it became necessary to hoist one of them out.

On the 24th, the pumps were at work again, but the weights attached to one of the buckets broke off.

The other was kept at work, and the water was lowered rapidly, showing the dam to be tight.

On the 25th the dam was entirely free of water, and the excavation with the windlasses was resumed, and the carpenters were employed in placing another tier of shores near the surface of the rock.

The weather being very stormy (December 29th, seventeen inches of snow fell), but a small force of labourers could be kept at work, and they were employed in assisting the carpenters with the shoring.

January 1, 1835, the weather having moderated, the mud machine was set to work again, and we were enabled to lower down the pumps so as to drain the upper end of the dam to the bottom, and clear off the mud.

January 2nd, the men who were excavating around the foot of the pumps touched the rock with their shovels.

The dam being now in very fine condition, preparations were again made for commencing the masonry, and on the 3rd the mud was entirely washed off the rock for one-half of the length of the dam; the surface of the rock was seen to be extremely irregular, as if it had been worn into deep cavities; on this day, also, the masonry was commenced.

The pumps were lowered so far as to rest upon the rock; the mud machine, too, was lowered to its utmost extent, but was found to be too short to reach the bottom, being over a deep cavity in the rock; there remained in the dam, however, but a very small quantity of mud in the cavities of the rock; it was determined to remove the machine, and that the windlasses should take its place.

About fifteen cubic yards of masonry were laid this day in hydraulic cement, and the pumps were not worked during the night, that the masonry might be covered with water, although there was no apprehension of its being affected by frost at so great a depth. The night proved to be extremely cold, and on Sunday, January 4th, the river was covered with ice sufficiently strong to bear a man.

Being thus cut off from a supply of stone, a stop was put to the masonry and all our other operations.

Every effort was now directed to the removal of the machinery, and to placing it in a state of security. The steam scows, pile drivers, mud scows, &c., were removed, and they were drawn upon the flats under the causeway of Analostan Island, and under the lee of the causeway of the aqueduct. The pumps, mud machine, and windlasses were taken on shore.

The dam, No. 2, was covered with sheet plates treenailed to the ties and shores, with an inclination down stream to facilitate the passage of the ice over, and to prevent its falling into the dam, should the freshets rise to that height.

The puddling of dam No. 1, was brought up to the level of high water mark, and the ties, shores, &c., secured.

The ice breakers to both dams were completed. This being done, the campaign of 1834 closed.

1835.—Although the winter had been extremely rigorous, and a great quantity of ice had formed in the river, it passed off without the slightest injury to the coffer-dams, which were therefore in good condition for recommencing the work early in the season.

The campaign, however, did not open until the latter end of April; Congress having declined further aid to the work, funds were raised by individual enterprise.

The citizens of Alexandria, with their usual public spirit, subscribed the amount required by the engineer for the operations of the year, and on the 21st of April, the board of directors ordered the work to be resumed.

On the 22nd of April, a small force of carpenters and labourers were engaged in stripping dam No. 2 of its winter covering. The pumps were put in place, the steam engines were brought back to their positions at the dam, and windlasses were erected for hoisting out the small quantity of mud remaining in the dam. The railways were laid, and a double derrick, for hoisting in large stone, was placed upon them. See figures 1 and 2, p. 147.

These arrangements being completed, the pumping was recommenced on the 14th of May, and the dam was entirely freed of water to the rock in ten and a half hours, with only two pumps, and it was found to be perfectly tight.

It is worthy of remark, as a proof of the tightness of the dam, that for a space of nearly four months, the water inside did not reach the level of high-water mark by twenty-two inches.

Foundations.

On the 15th the windlasses were at work hoisting out mud, and the masonry was begun. The stone laid in the winter was found to be very solidly united, the cement having a most excellent set. To insure the safety of the dam, the masonry was now extended to the oak piles, so as to cover the entire space within, excepting a few feet at the down-stream end, where the pumps were placed.

On the 17th the mud was all removed, and the rock entirely bare. The windlasses were now removed, and the railway extended to receive another double derrick.

The railways were constructed thus: twelve-inch square timbers, of heart pine, were placed parallel to each other over the heads of the inner row of oak piles, and firmly secured to them lengthwise of the dam; flat iron rails were placed on the inner edges of the timbers, and upon these were placed two carriages of timber. One end of each carriage projected ten feet beyond the dam

over the scows ladened with stone, these ends were stiffened with braces of iron; iron rails, the profile of which was a semi-circle, were laid upon the carriage, and upon these the double derricks, which moved on grooved wheels fixed under each foot. Level with the base of the pyramid or derrick, a platform was extended, upon which the winch for hoisting was placed. The derricks were each worked by four men and a boy; the men at the cranks and the boy at the slack of the rope to take it up as it wound upon the drum. Stones, weighing from three to four tons, were by these means hoisted up and lowered into the dam with great ease.

I am indebted to Lieutenant Bartlett, of the Corps of Engineers, for the plan of the wheels on these derricks.

The maximum number of masons capable of working to advantage was now employed, and their confidence in the strength of the dam was such, that they worked without the slightest apprehension of danger, and the pier rose rapidly under their efforts.

A spectacle so unusual as that of men busily at work so far below the surface of the river, seemed to interest the public exceedingly; but to the engineer, whatever might be his confidence in the ability of the dam to resist the immense weight, which he knew to be constantly pressing upon it in the most insidious form, the sight was one which filled him with anxiety, and urged him to the most unceasing watchfulness.

The masonry was carried up perpendicularly until it reached the second tier of shores from the bottom, where it was made to assume the shape and dimensions originally designed for the pier.

It being considered too hazardous to take out the lower tier of shores, they were built in with the masonry, but as the masonry reached successively the shores above, the sides of the dam were braced against the wall, and the shores taken out.

The greatest pains were bestowed in tempering the cement, and ascertaining the proper proportion of sand; care was taken also in selecting stone of good quality and of large size; none were admitted whose beds did not exceed the faces at least four to six times, not only on the face of the work but entirely through it. No small stone were used, except to fill up the spaces formed by the irregular shapes of the larger ones; and the whole was well bedded in cement, no grouting was permitted. Cement was used to the height of two feet above high-water mark, and above that common lime mortar; the whole was pointed with cement.

The ice breaker at the head of the pier is of cut sienitic granite, from Sandy Bay, Massachusetts. The two lower courses, commencing five feet below high-water mark, were twenty two inches thick, and the remainder ten feet above high-water mark, were eighteen inches thick, no stone being of less size than twenty cubic feet, and the whole was laid in cement.

On the 21st of June, the masonry was on a level with the top of the dam. The derricks, railways, &c., were then removed, and two booms were substituted for them, to raise the masonry to the intended height, twenty-nine feet above the plain of high water.

Notwithstanding a delay of some days, occasioned by a breach in the canal, which cut off the supply of stone, and the time occupied in removing the derricks and railways and erecting the booms, the pier was completed on the 1st day of August. As the masonry advanced the pumps were but seldom used, the water being allowed to rise with the masonry, in order to give a set to the cement; and when there was no longer a necessity for pumping at dam No. 2, the engines, &c., were removed to dam No. 1, arrangements for the pumping and excavation of which having been in progress for some time.

The machine used last year, for raising mud, proving to be so unwieldy, it was determined not to use it again, and in its stead windlasses were erected over the centre of the dam, lengthwise of it. They were worked by the steam-engine, and were capable of raising nine buckets at a time; they were found to be much more expeditious in raising mud than was the machine, and they were much less liable to get out of order.

The puddling, which was left last year on a level with high water, was filled up to a level with the ties at the top of the dam. The shoring required for the depth of water was arranged in the dam, ready to be fitted and keyed up as the water lowered them to their places.

On the 20th of June, the President of the United States, and the members of his Cabinet, having honoured the work with a visit, the two pumps in dam No. 1 were set to work, and performed admirably, and lowered the water very fast; but it being intended merely as an exhibition of their powers, the pumping was not continued long, as the shores were not quite ready to be keyed up.

On the 23rd, the water in dam No. 1 was lowered to the level of the second tier of shores. The oak piles being very irregular, a great quantity of blocking was required between them and the sheet piles; the blocking was also necessary to bring a proper bearing upon the stringers of the shores, which in consequence of the want of bearing were not keyed up until the day after that work was done.

On the 26th, the water was pumped out to the mud, and the third tier of shores were placed.

This dam did not prove to be so tight as was No. 2; at this stage of the work, several small leaks were observed around it, and one pump was constantly required to keep down the water.

On the 27th, the shores of the third tier were keyed up, and the excavation was commenced. The machinery of the windlasses, however, soon required overhauling and arranging, but on the 29th the excavation was continued.

On the 30th, the leaks increased, and the excavation was discontinued. The labourers were employed in boating clay to replace the puddling, which had settled a little.

July the 1st, the excavation was resumed, but the leaks increased beyond the capacity of the pumps, and the dam filled.

The difficulties encountered in this dam presented themselves at a much earlier period than our experience in dam No. 2 could have led us to expect, and they were of a much more serious character. This is attributable mainly to the fact, that the puddling, a very tenacious red clay, had been in the dam so long as to become too compact to settle down and fill the cavities formed by the water which undermined it.

The first leaks that occurred were through open joints in the sheet piling Various expedients suggested themselves for stopping these leaks; the first was to drive a sheet pile through the puddling to cover the open joint, but it was foreseen that the "montant," or sash pieces, resting upon the mud, would prevent the pile from coming in contact with the sheet piles to cover the open joint; it was therefore not tried. The next was to turn the pumps upon the puddling, so that by softening it, and increasing the weight somewhat, it might the more readily settle.

This process succeeded for a time, but it soon became necessary to excavate the puddling over the open joint, as low down as we could, and then with a heavy piece of sheet piling, used as a ram, to force the puddling down; this succeeded also for a time, but as the excavation of the mud advanced, and the leaks forced their way under the "montant" piles, more effectual means were required, and the puddling was therefore excavated from fifteen to twenty feet in length, over the leak, to a depth of eight or ten feet, a bank being left on the outside to keep out the tides. By keeping the pumps in motion, the water inside could now always be kept down within certain limits. A smooth pile, eight or ten inches in diameter, was then selected, and driven through the puddling to the cavity underneath; the pile was then drawn (the clay being so stiff that the aperture formed by it remained open), and a communication was thus opened with the leak. The period of low water was seized upon, the pumps were turned upon the puddling, and a head of water was created over the opening made by the pile. Dry powdered clay, previously prepared, was thrown in, and being carried down by the force of the water, it filled the cavity below, and stopped the leak.

This expedient, like the others, had its limits, for as the excavation of mud went on, the weight of water increased from without, and it became impossible to create a sufficient head of water to counteract it.

The method of driving piles was nevertheless continued, and they were known to have pierced the leak, by the water following them when drawn. The pumps were not used, but fine clay was poured down the opening until it was filled; a pile, square at the lower end, was then inserted, to force down the dry fine clay. This was a very slow operation, but still it succeeded.

At first these piles were driven by a heavy block of timber, worked by hand over a sheave, suspended at the end of a crane, but the leaks were of such frequent occurrence, and it being apparent, also, that the whole of the puddling must be packed down in this way, a light pile-driver was constructed especially for that use.

By constantly persevering in this method, we finally succeeded in reaching the rock at one end of the dam, but not in time to clear it off and commence the masonry before the winter set in.

Southern Abutment.

Early in the season preparations had been made for constructing a dam for the southern abutment, and it was commenced on the 1st of July, with such modifications and improvements as the experience gained on the 1st and 2nd dams suggested.

The abutment being 34 feet long, and 21 feet thick, with circular wing walls 13 feet average thickness at base, and 69 feet long, the dam was formed so as to enclose the area of the abutment, and leave a small space between the interior of the dam and the masonry.

The interior framing of the dam, as low down as the surface of the mud, was built upon the shore, and was then launched and floated to its position. The framing was as follows:—The lower stringers to rest upon the mud, timbers 18 inches square were laid upon the trace, and simply halved and bolted together at the angles; upon the inside of these, posts 18 inches square and 16 feet 6 inches long, were erected, 8 feet 6 inches apart from centre to centre, in the main body of the dam, and in the wings they were arranged to divide the space uniformly.

These posts were notched on to the stringers, and against the posts were placed the shores, 15 inches square timber. The shores were cut bevelling at the ends, and corresponding notches were cut in the posts, with oak wedges underneath the shores, for the purpose of relieving them when required to be taken out.

The posts and shores were secured to the stringers by two iron straps, with an eye in one end, let into the stringer by a mortise, through which a bolt was dropped by a hole bored from the top. The opposite ends of the iron straps were secured to the shores by a gib and key passing through a mortise in the shores and straps.

Above these, 4 feet 6 inches in the clear, was placed another set of stringers and shores, the stringers 16 inches, and the shores 14 inches square, arranged and secured as those below. Nine feet above this, the top tier, on a level with high water, was placed. The stringers of this tier were 13 inches square, and the shores were 12 inches square. The shores of this tier were not bevelled at the ends as the others, but were set square against the posts, and secured simply by a frame bolt passing through the stringer and post into the ends of the shore.

The ends of the dam were braced by timbers the same dimensions as the shores in each set, let into the stringers with a bearing joint, and secured by

a bolt. The frame was then braced to prevent its wracking, by pieces of sheet piling placed diagonally on its sides, and bolted to the posts on the inside.

The outer side of the stringers were dressed, and each set placed fair above each other.

This framing was floated to its position on the axis of the aqueduct, and was made to sink in the water by proper weights, until the lower stringers rested upon the mud. The pile drivers were placed upon opposite sides of the frame, each with a sheet pile suspended in the planes, and as soon as the frame was arranged in its place, the piles were dropped, and driven and bolted to the stringers, thus securing the frame in its position. The sheet piles were then driven all around, resting against the faces of the stringers, without "montants" or other guides, and *every* pile was driven to the rock. With respect to the outer rows of piles of this dam, they resemble those heretofore constructed, with the exception of the "montants," which were dispensed with, and in their stead temporary guides were used and withdrawn as the sheet piling progressed. Every oak and sheet pile in this row was also driven to the rock. The stringers and ties were all of white oak. The stringers were bolted together, and the joints were covered by short pieces that embraced each, five to seven oak piles. The ties were placed at every other oak pile. Before we enumerate the advantages of this *new* mode of construction, it may be permitted to point out what we consider defects in the old. In the first place, then, the interior row of oak piles used in dams No. 1 and 2, were found to be not only *useless*, but *pernicious*, inasmuch as they cannot be procured of precisely similar diameters, and they could not be worked to *pattern* without great expense, and even then, it was nearly impossible to drive them in so great a depth so accurately as to preserve the alignment all the way down.

Secondly.—The irregularity of the oak piles then affected the sheet piling, because the guides by which they are driven rested against the oak piles; the sheet piles were thus often made to pass each other, and leave open joints.

In dam No. 1, a badly driven oak pile which projected very much into the dam, was cut out, and others that were out of line required to be notched, and of course much weakened, in order to place the stringers for the shores in line: nevertheless, the stability of the dam did not appear to be at all effected. Hence the opinion that these oak piles were both useless and embarrassing.

Thirdly.—The montant piles were found to have caused nearly all the leakage in dams No. 1 and 2. It was under them that the sand and gravel and water found their way into the dams.

Fourthly.—The water in the first dams required to be pumped out to certain depths before a tier of shores could be placed, and when it was pumped out, the space between the oak and sheet piles allowed the sheet piles to spring inwards, by the weight of the puddling, before it was possible to block in between them all around.

Another objection is, that the length of each stringer and shore has to be determined, framed, and fitted before they can be keyed up, and this not for one tier only, but in fact every tier has to be so framed and fitted inside of the dam—an operation involving great inconvenience and delay. All these objections, and they are serious ones, are believed to be obviated in the mode of construction ultimately adopted.

In it, every pile being driven to the rock, the only apprehension of leakage will arise from open joints of the sheet piling, and if this should occur, and it may, by the point of a pile being turned by an obstacle in driving, the joints can be sufficiently closed by driving another pile to cover the opening, there being no montant or sash pile to prevent it.

The inner row of sheet piles being in immediate contact, or resting against the stringers of the shores, there can be no possibility of their springing with the weight of the puddling or pressure of the water, without crushing the shores.

And the shores themselves are made to act as ties, by means of the iron straps at their ends, and prevent the dam from spreading from the weight of the puddling, and of the water in the dam as the tide ebbs (the dam being tight, and having been filled by high water flowing over the top, or by other causes).

The dam, as soon as it is completed, can be pumped down to the surface of the mud, as also the shores required above the mud forms part of the frame work of the dam. Again, the shores and stringers required below the surface of the mud can be framed and fitted upon the sand, inasmuch as we may assume the interior of the dam to be some definite figure, and its dimensions therefore known. In this manner has the dam for the southern abutment of the aqueduct been constructed, and it is a matter of great regret that it could not have been altogether completed and tested this season; but a force of mechanics sufficient for the purpose could not be obtained; another extensive work in the vicinity being in progress at the same time, the demand for labour was very great. Previous to the commencement of this dam, a saw-mill had been contrived by Mr. B. F. Miller, the master carpenter and superintendent of the work, an experienced millwright, and a man of great mechanical ingenuity. It was erected upon the float of one of the steam scows, and was driven by the steam engine at work upon the pumps.

This machine not only saved great expense to the company, but it enabled us to execute much more accurate work, that could not otherwise have been done. By this machine two saws trimmed at once both edges of a sheet-pile perfectly parallel, and enabled us to obtain joints more perfect than we could either by hewing or planing. There was attached to the machine a circular saw also, which was used for cutting out oak wedges and other small pieces.

The work done by the circular saw alone, would nearly have covered the entire cost of the mill in one season. With it, one carpenter and one labourer performed, in one day, the work which last year required from ten to twelve carpenters.

On the 7th of December the winter set in, and the campaign of 183 closed.

Lieutenant M. C. Ewing, of the fourth regiment of artillery, has served wit me during the whole period as my assistant, in whose zeal and industry combined with his theoretical attainments and practical experience, I hav great confidence.

Lieutenant R. S. Smith, of the second regiment of infantry, was temporarily attached to my party, and rendered very efficient service.

Accompanying this report, are detailed drawings of all the machinery used and of the work itself, and also detailed statements of the expenditures of each year, including the cost of machinery, &c. &c.

All of which is respectfully submitted, by

Your very obedient Servant,

W. M. TURNBULL,

Captain and Assistant Top. Eng

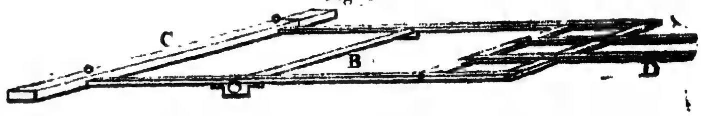
ROAD ROLLER.

Sir,—I beg to enclose you a drawing and description of an improved Roller for consolidating new materials on the public roads, recently purchased by the Surveyors of the parish of Lambeth. It not only act beneficially in common with all other Rollers, but from the compactness o the frame, and the facility of turning sharp round, is available in narrow streets, without inconvenience to passengers and carriages.—Yours, &c.

6, *Chryssell Road, North Brixton.* STEPHEN MUNDY.

N.B.—This is not the first on this construction which has been made, bu it is the largest.

Fig. 2.



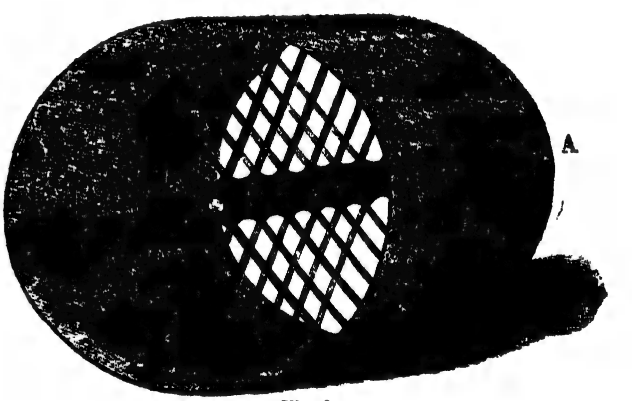


Fig. 1.

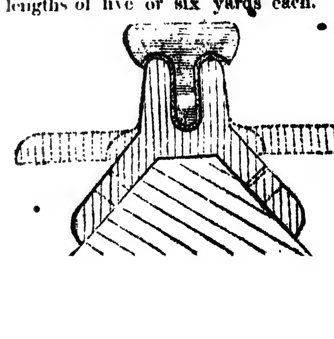
Fig. 1.—A. The Roller, consisting of seven distinct cylindrical wheels wit spokes and boxes, and fitting close to each other at the edge. They are o cast-iron; five feet in diameter, and four feet wide; and weigh three tons.

Fig. 2.—B. Wrought iron axle, engine-turned; three inches diameter.— C. Balance weight to the shafts;—necessary from the weight of the shafts and frame—and forming a shifting scraper to remove stones or rubbish sticking on the roller when in work.—D. Wrought iron frame and shafts.

RICHARDSON'S PATENT COMPOUND RAIL.

This rail is considered by its contriver as possessing advantages over othe rails in common use, in point of economy. Several patterns of it are constructed, some designed for chairs, others for continuous bearings, for which latter plan it is thought to be more particularly applicable. We have accordingly figured one of the latter forms, which is explained in the following description. The dotted lines which we have added, show the form o another pattern, adapted for bearings flat at the top. The figure is drawn to a quarter of the real size.

The top rails are of wrought iron, and weigh from twelve to twenty pounds per yard, and are rolled in lengths of five or six yards each. The lower rails are of cast iron, and can be made of such strength and weight, from one to two yards long, as may be suitable for the traffic which the line is intended to convey.



The wrought rail is bedded in the groove of the cast rail, with compressed felt, and connected together by wrought iron cotters (with allowance for expansion or

to allow of the wrought rail being reversed or exchanged when found necessary from wear, without disturbing the cast rail. The cast rail can be fixed to the blocks or bearers with the patent vertical ties, chairs, and traverses, or in any of the usual ways.

HARPER AND JOYCE'S STOVE.

We have been favoured by a correspondent in Paris with the following important extract from a French journal, which we are happy to lay before our readers in a translation. As containing the opinion of Gay-Lussac, the most eminent French chemist of the day, on the above stove which has excited so much curiosity of late, we hope it will be both interesting and useful. Relying on this most respectable authority, we feel it our duty to caution our readers against the use of these stoves, at least until the inventor has rebutted the heavy charge of M. Gay-Lussac.

It will be seen, that the invention *does not completely obviate* the fatal effects arising from the use of charcoal in close rooms—a practice, the dreadful consequences of which every winter proves, and few more fearfully than the last, recording the sacrifice of four lives in this way, at the seat of General Wyndham. We know not what is the use of a Board of Health in this country, if they do not interfere in such a case as this; and recommend the government to refer the invention to some eminent chemist, that his opinion may be formally given upon it, and officially made public.

"The attention of the Parisian public has been greatly occupied by the announcement of a new species of combustible, or fuel, which gives out neither smoke nor vapour of any kind; and which may be used in stoves, not merely portable, but capable of being carried from one room to another with the same ease as a chair, stand, or similar piece of furniture. This valuable substance is to enable us to warm apartments of any size, at a comparatively trifling expense! and without subjecting us to any of those numerous inconveniences attending open fire-places, which frequently annoy us with smoke, in spite of our best chimney doctors; or else emit heat very imperfectly from the logs of wood consumed in them. After having taken out its *brevet d'invention* in Belgium, it has come to display its marvels here in Paris! and completely revolutionize our domestic economy. An apparatus of the kind is now in use in the Hall where the Academy of Sciences holds its meetings, heated by the wonderful substance alluded to, which is *said to be* free from all impurity, and to give out sufficient warmth without the least smoke or other exhalation. All this was well calculated to excite strong curiosity, which looked impatiently forward to an explanation of the mystery—a solution of the grand problem; for the Academy of Sciences being a temple of science, and not a bazaar for new inventions and contrivances, it is not in the habit of receiving partial confidences in regard to scientific discoveries; but requires that the communications made to it, disclose every thing, without the slightest reserve. Its office is to diffuse light—not to keep it hidden under a bushel. With the schemes and interests of individuals it has nothing to do, but looks only to the advancement of science and the welfare of society; it therefore affords no countenance to discoveries, which are not completely revealed to it. Nevertheless, in this instance, the usual course of the Academy was departed from: M. Delessert who submitted the apparatus to the Academy, explained its contrivance, and exhibited it with the fuel in a state of ignition; but he did not explain the composition of the latter. Without doubt he was not authorized by the inventors to reveal any thing further; but then they evidently committed a mistake, and must have supposed that the Academy of Sciences was just the same as a Society for the Encouragement of Arts and Mechanical Inventions; whereas they ought to have known that, by making a mystery of their contrivance, and not acting conformably with the regulations of that body, they forfeited its favour. In so acting they were very ill-advised, since they could hardly expect that their secret could remain concealed from so many scientific men. In fact, within less than a quarter of an hour it was detected; therefore their caution had no other effect than to deprive them of the merit of frankly disclosing it, which they might have done with perfect security, their property in it being guaranteed to them by the patent they had taken out. In regard to the invention itself, it is far from perfect: while ingenious in its idea, it is apparently very immature in execution, though possibly something really useful may eventually result from it.

The apparatus presented to the Academy consists of two cylinders, the first or outer one being fitted up so as to resemble a sort of elegantly-shaped vase. This cylinder contains within it another, perforated with holes, for the admission of air, and holding the combustible matter; which is neither more nor less than well calcined charcoal, prepared after a particular manner, with the view of preventing the formation of carbonic acid gas, which, as is well known, becomes highly dangerous when the air is strongly impregnated with it. It appears that the formation of this gas is hindered by saturating the charcoal with soda or potass, whereby as quickly as the gas is generated, during combustion, it is absorbed by the base and combines with it, forming a carbonate of potass or soda, which remains in the ashes. Nevertheless, the gas is not so completely absorbed but that some portion of it escapes, as was evident enough at once, on an experiment for that purpose being made. At the same time, there was the principle of an application which may in time be rendered exceedingly serviceable, *when it shall be brought to perfection.*

As to the economy of such an apparatus; it may be easily conceived, if we take into account not the first cost of the combustible material, which is by no means cheap, but the use made of it, whereby none of the heat produced is lost or wasted. It is ascertained that from the fire-places we now make use of, we do not obtain above five per cent. of the caloric supplied by the wood consumed in them; while in this new apparatus, which being free from smoke or vapour, may be placed in the middle of a room, there is not the slightest loss of heat.

Such was the opinion we at first formed; but our opinion is now altered, and we are enabled to speak more positively as to the real value of this pretended discovery, thanks to M. Gay-Lussac, who has considered it his duty to put the public upon their guard in respect to it. And that eminent chemist deserves their thanks for having condescended to examine into its merits; in doing which he has acted as becomes the member of an Academy of Sciences, professing to propagate truth, and expose and dispel error.

Having examined the charcoal imported from England, M. Gay-Lussac found it to consist of light and well-burnt wood; but with regard to the alkaline substance, soda or potass, with which it was supposed this charcoal was saturated, he could detect so very slight (minimum) a portion of it, that he very much questions whether the charcoal had undergone any preparation of the kind at all. In fact, the charcoal does not contain more than a four-thousandth part of such alkali, which is about the proportion every other species of charcoal naturally possesses; so that quite as much carbonic acid gas escapes during combustion as from an ordinary charcoal fire. Consequently this new apparatus cannot be made use of without incurring precisely the same dangers and risks that attend the others. And this is what it is highly important the public should be aware of.

Regarded in the light it must now be, after what M. Gay-Lussac has stated relative to it, this apparatus loses even the merit of novelty; because, with the single exception that it is more elegant in appearance, it is nothing else than the *brasero* of the Spaniards; or, as M. Thénard remarks, the common charcoal-pan used by our retailers in the open streets. But in order to make use of this English warming apparatus with any safety, within doors, it would evidently become necessary to *keep our windows open!* and such being the case, it is far better to adhere to the stoves *(poeles)*, employed by us at present, which give out about nine-tenths of the caloric from the wood burnt in them."

BLASTING OF ROCKS BY GALVANISM.

That gunpowder may be fired by the action of a galvanic battery, is by no means a new discovery; nor that this may be effected at a very considerable distance. We are not, however, aware of this power of the galvanic fluid having been extensively applied to practical uses; and as it appears to be capable of such applications, we feel it a subject of interest both to ourselves and our readers, to state what *has* been done, and to give a guess or two as to what *may* be done with this comparatively new power.

The inefficiency of the common modes of blasting under water, and the danger attending their use in mining operations, are well known. Col. Pasley stated, at a meeting of the Institution of Civil Engineers, on Tuesday, April 10th, that for blasting under water, Pickford's fusee cannot be calculated upon with certainty, except at moderate depths. Mr. Bethell, who for some years past has been engaged in inquiries and experiments on diving, and is the patentee of an improved diving dress, favoured the Institution on the following meeting, April 24, with the result of his practical experience of the effects of a blast ignited by galvanism. This he had been led to devise by having frequent occasion to blow off the decks of sunken vessels, in order to enable the divers to reach the cargo. We will first describe the usual mode of conducting this operation, which is as follows. The charge of powder is enclosed in a tin canister and deposited in the requisite position in the wreck. It is lighted by means of a sort of quick-match, made of cotton steeped in spirits of wine and gunpowder, and then dried. This match is protected from the sea-water by an Indian-rubber tube inclosing it, and inserted water-tight into the canister. These precautions being carefully taken, the fire is conveyed with tolerable certainty to the charge; but as it runs along, it of course blows up the Indian-rubber tube;—a very expensive process when the depth of the water is considerable.

We will now proceed to describe Mr. Bethell's mode of effecting the same object: we could have wished to illustrate it by a sketch, but are unavoidably prevented by want of time. We will, however, undertake to render the matter clear to any one who has ever seen a galvanic battery in action;—perhaps to some others besides. It is well known that a piece of platinum or iron wire, when made to connect two copper wires leading from the two poles of the battery, instantly becomes red-hot, and capable of igniting gunpowder, or even of lighting a spirit-lamp. The problem for Mr. Bethell to solve, was just this: to introduce this same piece of platinum or iron wire into his charge of powder, and keep open when placed in its situation under water, its connexion with his galvanic apparatus in his boat above. This object he effected as follows. To consider first his canister;—in the top is fixed a cork coated with sealing wax, through which descend, water-tight, two vertical copper wires reaching into the middle of the charge. These are separate during their whole course except at bottom, where they are connected by a piece of platinum or iron wire; and at top they rise a little way above the cork, and are curled round into two distinct loops. After the charge is introduced, the top is cemented on the canister with putty. This then being all ready for the explosion, let us consider, secondly, Mr. Bethell's chain of communication. Now, here the difficulty is, that we must have not only two wires, but two wires *insulated*, kept totally distinct as far as their power of communicating the galvanic action is concerned. For this action is wanted *in the canister*; not in the boat, nor in the sea-water. For this purpose, Mr. Bethell coats the wires with a non-conductor; the best he considers to be the caoutchouc solution or varnish prepared by Macintosh and others. His wire is about as thick as common bell wire, and wrapped round with cotton thread, like the wire which the ladies use for millinery. Two of these cottoned wires are

coated with the varnish; when dry they are connected together by thread, and form a galvanic rope which may be laid by for use, in coils of any necessary length. The wires in the canister are likewise separately covered with cotton, and coated with the varnish; except at the two ends, at the one end of which they touch the platinum connecting wire, and at the other the galvanic rope leading from the boat.

And now, his apparatus being ready, see Mr. Bethell proceed to his operations. He has in his boat his galvanic apparatus, coils of rope ready prepared, and canisters ready charged. He takes out a coil; untwists the end for a short distance, removing also the cotton and varnish; he then twists the ends of the two wires one into each of the loops projecting out of the canister-top. The ends of the wires and the loops, both of which we have stated to be without varnish, are then coated separately with sealing-wax —a non-conductor likewise. Thus Mr. Bethell obtains what he wants; a double chain of communication, properly insulated, from his boat to his charge of powder in the canister. He has then only to send down a diver to lodge the canister in its proper place, letting out the galvanic rope as he descends; and on the return of the man, all is ready. The two wires are separated at the end of the rope in Mr. Bethell's hands; he brings one into connexion with each pole of the galvanic apparatus: the galvanic fluid finds an unbroken chain of communication down to the platinum wire in the canister: quick as thought the platinum grows red hot, and the explosion takes place as was desired.

Repeated experience has proved the efficiency of Mr. Bethell's contrivance. He has used a battery of six cells, and has found it sufficiently powerful for his purpose when using a galvanic rope of 100 yards. But so long a rope is seldom necessary in practice; for a charge of two or three pounds of blasting powder is found to produce no other effect than a wave on the surface, when exploded 30 feet under water. Mr. Bethell states, however, that one of Professor Daniel's six-cell batteries will ignite a charge at the distance of 3 or 400 yards. This would insure the safety of the operator in most cases where danger arises from the common modes of blasting; and with more powerful batteries, the effect might be produced at much greater distances;—miles off, says Professor Daniel. The same method is of course applicable to the blasting of rocks under water, an operation frequently necessary in the construction and improvement of harbours, and in other marine works. For these purposes also, Mr. Bethell's improved diver's dress, before alluded to, will be found of great service.

The economy of Mr. Bethell's process is very great. In all cases, the canister is of course blown up: by that which we have been describing, instead of an Indian rubber tube reaching from the boat to the charge, there is destroyed only about six inches of the galvanic rope;—about a foot of common copper bell wire saves, shall we say 50 yards of Indian rubber tube?

Mr. Bethell's improved process is plainly capable of application to all cases where blasting is used. In military engineering for example, it offers the grand advantage of enabling the officer himself in safety and at a distance, to apply the match (as he would say) to a number of mines almost simultaneously, and blow up the enemy with the utmost precision. A galvanic battery indeed would at first amuse both officers and men; but as the novelty wore off, it would take its place among the paraphernalia of war, and make itself respected. It is the frequent fate of useful inventions to be first laughed at, then tried, then used,—and last of all—praised.

We confess, however, that we have always far greater pleasure in witnessing the application of new discoveries in science and ingenious inventions in the Arts, to the pursuits of peace, than to the deeds of war. Man ever appears in the noblest light when employing his intellectual endowments in directing the powers of nature rather to the preservation than the destruction of life. And we do hope that great good will arise from the application of Mr. Bethell's process of blasting to the purposes of mining. Lay in a mine as many blasts as you please;—you may then call off all your miners and place them out of the reach of danger, and explode the whole at once. The superintendent of the mine in his office, or the proprietor in his parlour, may fire all the blasts:—the miner may lay the charge; but let him try to light the copper wires as long as he pleases,—the platinum remains cold till the galvanic fluid darts into it and fires up the explosion at once.

In conclusion, we heartily congratulate Mr. Bethell on his past success,—a success visible, tangible, practical: we bid him hope well for the future; and trust he will not resttill he has convinced the mining world especially, of the great advantages to be derived from the adoption of his invention.

JOINT STOCK COMPANIES.

During the last month there have been numerous companies projected, whose objects are immediately within the province of our Journal, therefore it behoves us to ascertain a few particulars regarding them, that we may be able to put our readers in possession of their merits or demerits. In our present Number we will confine our remarks to two companies of kindred objects—the French Asphalte, and the British Asphaltum Companies; and in a future Journal we will consider the others.

The first company to which we have to call the attention of the profession, is "Claridge's Patent Asphalte Company," formed for the purpose of introducing into this country the Asphalte in its natural state from the mine at Pyrimont Seyssel in France. As we gave some account of this material in our Journal, No. 4, page 60, it is unnecessary for us now to give any particulars of its nature; but we shall confine ourselves to the method of using the material, for the purpose of foot pavements, as lately adopted in Whitehall. The Commissioners of Woods and Forests being desirous to give it a fair trial before they sanction its general introduction, gave directions for the foot pavement to be taken up between Whitehall Chapel and Whitehall Place, and to be replaced by Claridge's Patent Asphalte, which was executed in the following manner. The stone paving was taken up and all the loose rubbish below, to the depth of 6 inches from the surface of the paving; it was then levelled and covered with concrete 6 inches thick, composed of Thames ballast and stone lime. The surface was floated, and then allowed to remain for three days to harden or set; at the end of which time, preparations were made for laying on a coat of the Asphalte. The mineral was brought to the spot in its natural state; it was then melted in portable furnaces with iron pots, similar to portable brewing coppers, out of which it was ladled while hot, and poured over the concrete to the thickness of five-eighths, or three-fourths of an inch. A screed or lath had been previously fixed, extending the whole breadth of the foot paving at distances of two feet, forming a gauge for floating or regulating the surface. As the Asphalte was poured out, one man with a trowel and gauge smoothed the surface, and another sprinkled upon it small pebbles passed through a sieve, which stuck to the surface and formed a protecting coat. As soon as the Asphalte was set (which was within an hour or two after it was laid on), the foot pavement was thrown open to the public. From the *present* appearance it would seem fully to answer the purpose intended; the surface is very hard and even, and is not affected by the wet. Nor do we anticipate that the heat of the summer will have any effect upon it, as it requires a temperature of 560° to melt it, which is about that of melted lead. The same Company have also substituted the Asphalte for the Dutch clinkers in the pavement of one of the stalls of the stables at Knightsbridge Barracks, in which has been placed a very restive horse. These two experiments we consider will give the material a fair trial; it appears to us that it is well adapted for basement floors, vaults, and cellars, both as a substitute for paving, and for covering the top of the arches to render them impervious to wet; as also for lining of tanks, troughs, and drains. But we do not consider it an advisable material for lining floors and roofs, or for any purpose requiring it to be laid on timber, as the material is inflammable, and would burn in a flame in case of a fire occurring in premises in which it was used. Nor can it be employed in London for roofs, without a special Act of Parliament, as the clauses contained in the Building Act will prevent its use for that purpose. We are not aware whether it be intended to submit the material to the severe test of covering the carriageways of London with it; we think the Company will do wisely not to hazard it. We understand that it has been applied for that purpose in Paris; but the traffic of Paris is so widely different from that of London, that what would answer in the former city is no criterion for the latter.

The next material, which we shall now briefly notice, is that of the British Asphaltum and Patent Coal Company. This company have not yet put their material to the test, otherwise than in specimens, which we have seen, and which promise to be good. We have inspected a table top made of the material, which was of a very close, black texture, hard, and difficult to make an impression on with the nail; the surface appeared capable of receiving a polish. There was also a specimen of three hard stock bricks united at the joint by this material; a similar specimen was thrown from the top of a house 40 feet high;—the bricks were broken by the fall, but the joints remained perfect. The British Asphaltum appears to be adapted for the same purposes as we enumerated above; and we are informed that the materials are indigenous to this country. From the statements of the officers of the company it appears that the Asphaltum can be furnished at a very low rate; that the company can lay it down as a substitute for Yorkshire pavement at about 4d. per foot: but this remains to be proved.

We shall continue our remarks on the newly projected companies, in the next Journal: in the mean time, we shall be happy to receive the opinions of our brethren in the profession concerning them; for it is our earnest desire, free from all bias, to form and express an impartial judgment on all new inventions and improvements in the Arts.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL SOCIETY.

A description of a *new Tide Gauge*, constructed by T. G. Bunt, and erected on the eastern bank of the river Avon, in front of the Hotwell House, Bristol, in 1837. The principal parts of the machine here described, are—an eight-day clock, which turns a vertical cylinder, revolving once in twenty-four hours; a wheel, to which an alternate motion is communicated, by a float rising and falling with the tide, and connected by a wire with the wheel, which is kept constantly strained by a counterpoise, and a small drum, on the same axis with the wheel, which, by a suspending wire, communicates 1-18th of the vertical motion of the float to a bar carrying a pencil, which marks a curve in the cylinder, or on a sheet of paper wrapped round it, exhibiting the rise and fall of the tide at each moment of time. The details of the mechanism, illustrated by drawings, occupy the whole of this paper.

INSTITUTION OF CIVIL ENGINEERS.

Mr. Mushet presented some specimens of malleable iron, in his opinion peculiarly adapted for railway purposes. The feature peculiar to this iron is, the omission of the refining process in its manufacture. The valuable properties of malleable iron being fibre and hardness, Mr. Mushet considers

that these are but imperfectly secured by the present process. Iron, as at present generally manufactured, receives the fibre from repeated heatings and rollings; but fibre thus acquired, is obtained at the sacrifice of hardness. The fibre of malleable iron may be injured by over-heating, by adding in the smelting furnace ores rendering the iron cold, short; or by the use of cinders, which, when in excess, cause the fibre to crystallize and produce brittleness. Some irons, however, are so exceedingly fibrous, that they admit of a limited use of cinders without deterioration. By omitting the refining process, a greater mass of fibre can be produced than in any other manner; and this fibre, in consequence of the iron not being exposed to so severe a degree of decarbonization, is stiffer and harder than that acquired by repeated heatings and rollings. The iron used for railways should be from good grey mine pig-iron, as the source from which the hardest and strongest fibre in malleable iron is derived. The use of cinder-pig should be excluded, on the ground that the quantity and quality of the fibre is injured; and if in the state of grey iron, its fusibility is so much increased, as to occasion great waste in the puddling and subsequent re-heatings.

Paper on the Canal Lifts of the Grand Western Canal, by James Green.

These lifts are not intended to supersede the use of locks in all cases, but in those in which a considerable ascent is to be overcome in a short distance, and in which the water is inadequate to the consumption of a common lock, or in which the funds are inadequate to the execution of the work on a scale adapted to such locks. These lifts are forty-six feet in height, consisting of two chambers, with a pier of masonry between them, similar to those of a common lock, and being of sufficient dimensions to admit a wooden cradle in each, in which the boat about to ascend or descend floats. The cradle being on a level with the pond of the canal, a water-tight gate at the end of the cradle and of the pond of the canal is raised up, and leaves the communication betwixt the water in the canal and in the cradle free, and the boat swims into or out of the cradle. The cradles are balanced by very strong chains running over three cast-iron wheels, and are so arranged that the water in the upper cradle is about two inches below the level of the water in the pond, the consequence of which is, that the upper cradle has a slight preponderance, just sufficient to set the machinery in motion; the weight of this additional water being generally about one ton; it may, however, be regulated at pleasure. The principle of action in always maintaining the equilibrium between the cradles, is the well known one, that a floating body displaces a volume of fluid equal to its own weight. The cradles, when full of water, or when either or both of them contains a boat, will balance in any position; an additional weight of water in the descending cradle being necessary just to overcome the friction and the vis inertiæ of the machinery and cradles. It is obvious that the weight of the additional length of the suspending chains on the side of the cradle which is the lowest must be counterbalanced; this is effected by attaching to the under side of each cradle a chain of equal weight per foot with the suspending chains; and this, elongating under the ascending, and shortening under the descending cradle, removes the disparity in weight. The strength of materials is the great desideratum in machinery of this nature; and though the lifts here described are but forty-six feet, and the boats about eight tons, yet the same method is applicable to much greater heights and much heavier tonnage. The advantages of these lifts over common locks are great economy of construction and great saving of time and water, the time occupied in passing one boat up and another down this lift of forty-six feet being but three minutes, whereas in common locks to pass the same height would occupy thirty minutes. Also the quantity of water consumed is about two tons for eight tons of cargo, whereas in common locks it is about three tons of water per ton of cargo.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

Amongst the many proofs of an improvement in our social state, we have to observe the greater frequency of conversazioni given by members of the higher ranks of society, distinguished for their taste and learning, to the professors of the liberal arts. An invitation of this agreeable nature was issued for the 2nd of last month by the Noble President of the Royal Institute of British Architects, Earl de Grey. To the interest afforded by the display of the beautiful works of art in the possession of his lordship, was added that of many highly interesting productions in history, landscape, and architecture, by eminent living artists, many of whom were present. Amongst the company were several noblemen and gentlemen, distinguished lovers and encouragers of art and science; and the charm of the evening was rendered complete by the presence of several ladies of rank, whose appreciation of the various works, flatteringly evinced to their authors, formed a very pleasing feature in this conversazione. The magnificent suite of rooms presented a very brilliant appearance, and the numerous attractions which they contained had the effect of retaining the company till a late hour.

The following distinguished noblemen and their ladies were present:— The Duke and Duchess of Sutherland, the Marquis and Marchioness of Lansdowne, Lord and Lady Burlington, Lord and Lady Lyndhurst, Lord Aberdeen. The family of the noble host, Earl de Grey, also graced the party by their presence. There were present also the following gentlemen, distinguished in the scientific world:—Sir Edward Cust, Sir Henry Halford, Sir Richard Westmacott, Sir William Newton, Sir Francis Chantrey, Sir John Rennie, Sir Jeffery Wyatville; numerous members of the Royal Academy; the President and several members of the Institution of Civil Engineers; of the Architectural Society, and of other scientific and learned bodies in the metropolis.

At an Ordinary General Meeting of the Members, held on Monday, the 9th of April, 1838,

P. J. Robinson, Esq., V.P., in the Chair,

His Grace the Duke of Northumberland was elected an Honorary Fellow.

The following gentlemen were elected as Associates:—Andrew Moseley, of 21, Lincoln's-Inn Fields; Edward Charles Hakewill, of 8, Kent-terrace, Regent's-park.

A letter was read from M. de Lassaulx, of Coblentz, acknowledging, with thanks, his election as Honorary and Corresponding Member.

Several donations were announced as having been received.

Mr. A. H. Renton read a paper "On the nature, properties, and elementary principles of Iron," in continuation of his course.

Mr. Britton, Honorary Member, read a very interesting paper, on the architectural characteristics of the *porticos* of Greek and Roman temples, and the *porches* of Christian churches. He commenced by some judicious observations on the necessity of adapting and applying designs to the climate, peculiarity of situation and destination of a building; and on the misapplication of the forms of ancient architecture to modern and trifling purposes: and further rebuked the enthusiastic admiration which is so constantly manifested, for every thing of Grecian origin. In the eastern parts of the globe, it was remarked, where architecture was at an early period advanced to high perfection, the climate impelled builders to provide a shelter from the heat of the sun, rather than from the violence of wind and storms. Hence even in the extremely ancient temples of Egypt, and the excavations of Hindostan, an anterior space was covered in, and fronted by a range of columns, forming, if he might be allowed to say so, a sort of architectural parasol. This arrangement he illustrated by referring to some beautiful drawings of Ellora in India, and Appollinopolis-magna at Edfou in Egypt, which, with many others subsequently noticed, were suspended in the room. In Greece, a similar appendage was universal; with an inclination of the roof, which produced the pediment, and thus completed the architectural composition of a portico. Mr. Britton proceeded to define the different parts, and the most common varieties of ancient porticos; illustrating his remarks by reference, first to the principal temples of Athens, Pœstum, and other Greek designs; and next to those of ancient Roman buildings. In noticing that of the Pantheon he cautioned the young architect against trusting too implicitly to the hyperbolical language of encomium used by Mr. Forsyth in his description of that portico; and passed censure upon the injudicious combination of curved and straight lines which it presents. Proceeding from the *portico* to the *porch*, Mr. Britton pointed out the occasional variation in the form of individual examples of the *porch*, its peculiar adaptation to the exigencies of a rigorous climate, and the circumstance of its forming more an object of utility, and less of paramount beauty, than the portico. That decoration, however, was by no means neglected in the porch, was proved by the drawings exhibited. Being so well suited to the climate of this country, it was not surprising that England presented an infinitely greater number of porches than any other part of Europe; it was indeed one of those members of ancient architecture which might be said to be indigenous to this country. The earliest examples remaining, were of the Anglo-Norman era. Mr. Britton entered into a minute description, referring to drawings, of those at Malmesbury Abbey Church; Southwell Collegiate Church; St. Margaret's Church, York; Bishop's Cleeve Church, Gloucestershire; Barneck Church, Northamptonshire; and Durham Cathedral (the Galilee); all of this early period. The fourth of these (at Bishop's Cleeve) has never been engraved, and from the sketches exhibited, it appears to be one of the most interesting porches now left; exhibiting a variety of ornamental mouldings, intersecting arches, and other curious features. The porches of Wells, Ely, Hereford, Lincoln, Salisbury, and Peterborough Cathedrals, particularly the two latter, afforded good examples of the earlier and middle periods of pointed architecture; those of a subsequent date being for want of time deferred till another evening.

At an Ordinary General Meeting of the Members, held on Monday, the 23rd of April, 1838,

J. B. Papworth, Esq., V.P., in the Chair,

Several donations were announced as having been received.

Mr. Renton continued his course "On the nature, properties, and elementary principles of Iron;" illustrating his observations by drawings, exhibiting the comparative advantages of various forms of section.

A paper was read by R. W. Billings, Associate, "On the plan and decorations of the Temple Church, London: particularly with regard to their typical signification in reference to the doctrines, customs, and ceremonials of the Knights Templars."

ARCHITECTURAL SOCIETY.

The above Society held a Conversazione at their Rooms, Lincoln's-Inn Fields, on Monday evening, April 9th. It was attended by a very numerous company of the profession, and patrons of Architecture; amongst whom we had the gratification of observing the noble Earl de Grey, President of the Royal Institute of Architects. A letter was read by the President, W. B. Clarke, F.A.S. &c., stating that his Royal Highness the Duke of Sussex, the Patron of the Society, was prevented from attending by indisposition. Numerous donations were then announced by the Secretary, from C. Manby, Esq., C.E., and J. Nash, Esq., Amateur Members; and from several other

members; after which the President delivered an address, of which we give the following abstract.

He began by briefly adverting to the first rise of the Architectural Society, and the objects for which it was formed—the obtaining of knowledge by the co-operation of the members, and the affording to their younger brethren of the profession such advantages as they themselves possessed; thus exhibiting the laudable character of the Institution, and disclaiming all feelings of rivalry with other and posterior institutions. He proceeded to notice, with much satisfaction, the honour and benefit conferred upon its members by the patronage of his Royal Highness the Duke of Sussex. On this noble prince, a high and deserved encomium was passed, for his constant readiness to further, by his countenance and support, the interests of science and art. After alluding to the interest felt by the late venerable Sir John Soane in this Society, whose direction the infirmities of age alone prevented him from assuming, the President proceeded to notice the advantages derived by the Fine Arts, and especially Architecture, from the patronage of a wealthy aristocracy. Referring our present advance in the Fine Arts to the encouragement of George the Third, as the original exciting cause of the genius of our countrymen, he anticipated great further improvement, especially in Architecture, from the increased diffusion of taste, and particularly of architectural knowledge, among the masses, both educated and uneducated; and this advance of taste and science was stated to be one of the leading objects of the Society. The address concluded with an expression on the part of the President, of diffidence in his own qualifications, and of an earnest desire to give place to some distinguished professor of Architecture.

The Rooms were hung with numerous designs, by members, of buildings now in the course of erection under their superintendence. Amongst these we observed the names of T. H. Wyatt, V.P.; George Mair, V.P.; George Moore, William Grellier, E. H. Browne, T. T. Bury, T. L. Walker, B. Ferry, &c. &c. Several portfolios were on the tables; that of Mr. Jos. Nash, Honorary Member, afforded great and deserved gratification. The drawing of the Weedon Aqueduct on the Birmingham Railway, by Mr. Dodsworth, excited considerable attention, from its great merits. Some drawings by F. Arundall likewise were the cause of much admiration. We must also remark that the window of stained glass, tastefully lighted up in the room, exhibited a remarkably fine specimen of that art; it is the work of Hoadley and Oldfield, of the Hampstead-road. The company separated at a late hour, evidently much gratified and interested by the entertainment afforded.

THE MANCHESTER ARCHITECTURAL SOCIETY.

The fifth *conversazione* of this Society took place in their Rooms, Mosley-street, on Wednesday evening, April 4th. There was a numerous attendance of the members and their friends, and the *soirée* was of a very delightful and instructive nature. Amongst the works of art exhibited were drawings by Prout, Stanfield, Cattermole, Aspland, Crouch, and R. Lane; two clever drawings by J. W. Hance, one a view of Windsor, the other a design for a new Exchange; several very spirited female heads by C. A. Du Val, &c. There were two cabinet pictures by Bradley, one by Liverseege, a fine landscape by J. W. Frazer, Esq., and a very clever painting ("a boy selling fish") by C. A. Du Val. George Peel, Esq., contributed three exquisite bronzes; and Messrs. Agnew, Grundy, and Zenetti, also furnished numerous works of art.

The Society being desirous of exhibiting the designs lately sent in competition for the Catholic Church in Manchester (under the impression that public examination is the most effectual mode of insuring just decisions in competitions), such architects as were candidates are invited to forward their designs as early as possible to the Society's Rooms, 45, Mosley-street, where every information relative to the proposed exhibition may be obtained.

LAW PROCEEDINGS.

VICE-CHANCELLOR'S COURT, *March 10th and 12th.*

HEATHER AND PRITCHARD *v.* POSTLEWHITE AND DAY.

This was a motion on the part of the plaintiffs, the contractors for building a new Roman Catholic Chapel, at Hereford, against the Reverend Mr. Postlewhite, and his architect, Mr. Day, for an injunction to restrain them from proceeding to finish the Chapel, which had been partly erected by the plaintiff.

The affidavits on the part of the plaintiffs stated, that in July, 1837, they entered into a contract with the defendant Postlewhite, to erect the chapel in question, under the superintendence of Mr. Day, for the sum of 5,681*l.* The defendant Day had power to dismiss the workmen, to remove such parts of the works as he should disapprove of, and employ other workmen in case of any negligence on the part of the plaintiffs. It was also agreed, that whenever the defendant Postlewhite received a certificate during the progress of the works from Day, that the amount of the works therein specified had been completed to his satisfaction, Postlewhite would, within the space of fourteen days, pay to the plaintiffs a sum of money equivalent to two-thirds of the value of the work done, and mentioned in the certificate, and pay the balance within one month after the whole was certified to have been completed. No certificate was to be given for a less sum than 750*l.*, and all moneys payable for any default of the plaintiffs, was to be deducted therefrom.

The plaintiffs' affidavits further stated, that the plaintiffs proceeded to execute the works in a proper manner, conformable to the specification—that during the progress of the works the defendant Day acted in an arbitrary, tyrannical, and capricious manner—that the plaintiffs verily believed the object of defendants was to get the chapel built at the expense of the plaintiffs, without paying for the same—that the defendant Day had refused to grant certificates, although work to a large amount had been done—that the defendant Postlewhite was a priest of the order of Jesuits, and had made a vow of poverty, and the plaintiffs believed he was unable to pay for the work—that notices were given from time to time by Day, and his two clerks of the works, which were capricious and unreasonable—that although the plaintiffs had put up sufficient scaffolding, Mr. Day had, without cause, objected to it as insufficient—that he had also complained without cause of the bricks, sand, and mortar, and had required more men to be employed on the works than were necessary—that on the 31st October they wrote a letter requesting a certificate—that in answer thereto they only received a letter, saying, Mr. Day would not be trifled with—that by reason of Mr. Day refusing to grant certificates, they became unable to proceed with the works for want of funds—that the plaintiffs wrote several letters to Mr. Day, and were answered by notices to proceed with the works—that upon the 7th of December the plaintiffs received notice to move their bricks and materials, and were excluded from the works. The plaintiffs' affidavits contained a variety of other statements, having for their object to show that the works were done by the plaintiffs in a sufficient and proper manner, and that there was no just cause of complaint.

The affidavits, on the part of the defendants, denied in the most positive terms the fraudulent intention suggested by the plaintiffs, of procuring the chapel to be built without paying for the same. The affidavits further stated, that it was well known to the plaintiffs that Mr. Postlewhite was a Roman Catholic priest, and that up to the time of the filing of the plaintiffs' bill, no doubt was ever suggested by them as to Mr. Postlewhite's ability to pay. Mr. Postlewhite's affidavit stated, that he had ample funds under his control to meet the payments of the contract. Mr. Day also denied, in his affidavit, the imputation on his conduct made by the plaintiffs, stating that he had no interest in the chapel, further than his professional employment as the architect, and that he was only desirous to do justice between the parties.

It further appeared by the affidavits, that Mr. Day had from time to time, during his absence from Hereford, received letters from Trow, his clerk of the works, and from Thornton, who succeeded Trow (which were set forth in the affidavits), complaining in very strong terms of the conduct of the plaintiffs and their workmen, in disobeying the directions and notices given, doing the works improperly, and using improper materials—that Mr. Day, finding it necessary to dismiss Trow, the plaintiffs immediately took him into their employ, and employed him upon the works until Mr. Day compelled them by a notice to remove him—that the plaintiffs disobeyed the notices of Mr. Day and his clerks of the works—that at the time when he received the plaintiffs' letter of the 31st October, he also received a letter from his clerk of the works, complaining of the works being done in a very improper manner and contrary to orders, and adding, that he was put at open defiance by the contractors. That in consequence of this conduct, the works were in the beginning of November suspended—that on the 10th of November the plaintiffs and their sureties, and Mr. Day, had a meeting, at which the plaintiffs undertook to provide proper scaffolding to Mr. Day's satisfaction, and to resume the works as soon as possible afterwards—that scaffolding having been erected, the plaintiffs resumed the works on the 21st of November—that Mr. Day was then absent from Hereford—that Mr. Thornton, his clerk of the works, discovered that the plaintiffs, instead of using bricks, the produce of the best kilns, as the specification required, were using clamp-burnt and inferior bricks—that in consequence of the complaints of Mr. Thornton, disputes arose, and the plaintiffs, on the 25th of November, quitted the works, and never after resumed them—that Mr. Day, on the 27th November, having been informed of these proceedings, went to Hereford, and in consequence of the plaintiffs having quitted the works, he afterwards, under the powers given by the contract, employed other persons to proceed with them, having previously given the plaintiffs notice to resume the works—that on the 30th of November the plaintiffs, instead of resuming the works, served him with a demand for a certificate, to which Mr. Day gave the following answer:—"In answer to your application for a certificate, I have to state, that in my judgment you are not entitled to one, and I therefore for the present refuse to grant it. When you shall have resumed the works which you have discontinued, and I am satisfied that the works done shall entitle you to a certificate, it shall be immediately granted for such a sum as in my judgment I shall think sufficient and proper." That the plaintiffs never did resume the works as required, and that it was questionable whether the works done were sufficient in amount to secure the due performance of the contract without calling upon the sureties. The affidavits, on the part of the defendants, stated a variety of instances in which the contract had been departed from, and amongst others, that although the contract provided that the plaintiffs should make no sub-contracts for any of the works, without the consent, in writing, of the architect, the plaintiffs had, without his knowledge, made sub-contracts for the plumbers', painters', and glaziers' works.

Mr. Knight Bruce (with whom were Mr. Jacob and Mr. Stuart) stated the case for the plaintiffs. Mr. Bruce said—The question which the court was now called upon to decide, was whether the defendants were to have the full benefit of the heretical bricks and mortar, the heretical timber and labour of the plaintiffs, without paying one single farthing for them? The court would have to decide whether this Jesuitical chapel was gratuitously to belong to the defendant, the Rev. Joseph Postlewhite. By the deed, Day became sole arbitrator between the parties, and supposing him capriciously or

corruptly to refuse to give any certificate, and declare the work not done to his satisfaction, the plaintiffs were concluded by his award, and deprived of their right at law to recover one farthing under the terms of the agreement. A court of equity would not however, he hoped, hold that a person who had given both his time and labour in a just and proper compliance with the stipulations of a solemn contract, should be deprived of all just remuneration by the capricious, corrupt, or even erroneous judgment, by which an arbitrator thought proper to withhold his certificate. It might happen, that an arbitrator, acting fairly and honestly, might arrive at an erroneous conclusion, and that great difficulties might thereby arise, which the court would find it difficult to correct; but before the court came to a conclusion of that description, it ought to satisfy itself that in the position in which Mr. Day was placed between those parties, he had acted impartially and judicially.

After a variety of other remarks, the learned counsel submitted, that the court ought to extend its protection to the plaintiffs. He said, that the court in this case could pursue no middle course; it must either consider, by the terms of the contract, the plaintiffs were entitled or not to receive a certificate, at the mercy and capricious will of Day, without his giving any reason. The injunction which the plaintiffs asked, was to restrain the defendants from proceeding with the works, the plaintiffs not objecting to waive the agreement, if the court would prevent its being set up in a court of law against an action to be brought by the plaintiffs for the work and labour actually done.

The Solicitor-General, Mr. Wigram, and Mr. G. Richards, appeared for the defendants; but

The Vice-Chancellor, without hearing the counsel for the defendants, proceeded to give judgment as follows:—

I shall not hear the other side. The question is not before me whether the plaintiffs shall be paid anything or not, or what shall be paid; that is a question which can only be decided at the hearing: but I am asked now by the plaintiffs in effect to prevent the progress of the building of that chapel, which is the subject of the contract, and which chapel, as I understand it, was by the contract to be completed on or before the 1st of November, 1838.

Now it really appears to me that it will be a very arbitrary and very tyrannical thing, after the course of conduct that has been pursued by these parties towards each other, for the court to say, that in effect the building shall not be completed; and that would be the effect of granting the injunction.

The right of the plaintiffs to be paid on the principle of *quantum meruit* for what they have done, remains unaffected if I refuse the injunction; but if I was to grant the injunction, it would be putting the defendants in a situation in which, according to the simplest view of the contract, and even the view taken by the plaintiffs themselves, they ought not to be placed.

I am desired to interfere on the ground, as it is alleged, of the arbitrary, oppressive, and tyrannical conduct of Mr. Day. Now, for aught I know, there may have been some instances in which Mr. Day may have been misinformed, and there may have been circumstances with respect to which he has formed an erroneous judgment; but I find in his affidavit, more than once, that he does positively, in the most express manner, deny that he has acted in any such spirit as arbitrator in a vexatious or tyrannical spirit; and I do find this, about which there is no dispute; that, in the first place, it was one of the things plainly specified, that all the bricks should be *kiln-burnt bricks*; and it seems to be admitted as a fact, that the bricks were *not* kiln burnt, but that, in effect, they were what are called *clamp-burnt bricks*. The allegation of the plaintiffs is, not that they were kiln burnt bricks, but that, with some exceptions, they were as good as kiln-burnt bricks: there is one plain violation of the specification; there may be a qualification of the violation, but the specification has been violated.

Then there is that said with regard to the iron tie, which in effect so far as there was, in the first instance, a making of the work according to the specification, clearly has been omitted; *that* is plain on the affidavit, which has been put in by way of reply to Mr. Day's affidavit. Mr. Day states what took place circumstantially; in some respects he is contradicted, but the substance of the fact, that there was a deviation from the specification, is admitted.

Then it should be observed, that Mr. Day of necessity could not constantly be on the spot. But what do you find? Why, you find that so long as Mr. Trow was the clerk of the works for Mr. Day, he writes the letters to him, stating the improper species of conduct on the part of the plaintiffs, and upon that, it appears that Mr. Day's mind was so much excited, that he came himself to Hereford and looked at the works; and then, though complaints had been made to him by Trow, that the plaintiffs had not been properly carrying on the works, he was personally satisfied in his own mind that Trow had himself not been sufficiently vigilant, and for that reason he dismissed him—that was on the 4th of October, 1837. Then it appears that Thornton was appointed to succeed Trow, and Thornton came to Hereford, and began his superintendence as clerk of the works on the 26th of October, 1837; and then we find that, from that time, Mr. Thornton is continually making representations to Mr. Day, by letter, as to the improper conduct on the part of the plaintiffs.

I admit it is exceedingly possible that in many of those representations made by Trow and made by Thornton there might have been something erroneous. But what was Mr. Day to do? It appears that Mr. Day made several journeys to Hereford on purpose himself to superintend what was going forward, and that it had been stated to him, both by the person whom he dismissed and by the person whom he subsequently appointed, that there were improper courses adopted;—then when he comes on the spot and sees what is going forward, am I to assume, because his judgment coincided with that of Trow and Thornton, that he has acted in an arbitrary, tyrannical, and capricious manner?

It appears to me, that though he may have been mistaken, and though perhaps he may have acted in a pettish manner with regard to the words he used, or with regard to the language he inserted in his notes, it is too much, upon these affidavits, for me to say he has acted in such an improper manner, that I am compelled to go against the language of the contract, which, as I understand it, does authorize his employing other workmen than those of the plaintiffs for the purpose of completing the works;—and that is the sort of very imperfect step towards an ultimate relief which the plaintiffs say they are entitled to, and to which, for aught I know, they are entitled,—that I am to stop the progress of the works, and that they are not to have the chapel completed by the 1st of November, 1838, if it can be. It really appears to me, I must say, that there is not enough upon these affidavits, as they are laid before me. There is not such a case made out as would justify me in saying that the conduct of Mr. Day has been that arbitrary, capricious, and tyrannical conduct with which he is charged, and which he expressly swears it is not; and it is impossible to say how much of bad conduct is to be passed over, and how much is to be visited with severity. If the plaintiffs had made out that in every instance they had complied with the specification,—there would have been ground for the complaint of arbitrary, tyrannical, and capricious conduct on the part of Mr. Day; that would be a very different case,—but that is not made out on the affidavits distinctly, on their own showing: and my opinion is, I am not at liberty to grant the injunction; and my opinion further is, that the injunction sought for is so little ancilliary to the relief which the plaintiffs asked,—that there is so little ground for asking it,—that I am bound to refuse the motion with costs.

April 19th.

SEMPLE *v.* THE LONDON AND BIRMINGHAM RAILWAY COMPANY.

This was an application to dissolve an injunction which had been granted to restrain the Company from laying down, carting, &c., any clay, &c. on the Commercial Road, which runs between the plaintiff's wharf on the Regent's Canal and the station of the company in the Hampstead Road, and from continuing any impediment to the plaintiff's use of it. The facts were, that a person named Reading, who had contracted with the company to carry 20,000 yards of clay to their station, being on the 1st of March last unable to go along the usual road into the station, by reason of the thaw, carted the clay up the Commercial Road, and deposited fifty-three loads opposite the plaintiff's gates, with the view of wheeling it across planks and a scaffold, erected for the purpose, over the wall into the company's grounds. On the next day he received a notice from the engineer of the canal, not to cart any more, as it caused an obstruction and the road was private: upon this, the scaffolding was taken down; but the clay remaining, the bill was filed on the 10th of March for the injunction, which was granted on the 12th; before it was obtained, the defendants began to clear away the clay, and it was all removed on the 13th.

Mr. Jacob, for the defendants, insisted that the depositing was only a *temporary* measure, and had been done by their contractor in ignorance, who ought to have been a party defendant; that the company had a right of way up the road, and that no obstruction had been created; and that plaintiff knew the clay was being removed when he applied for injunction, and ought to have delayed proceedings.

Mr. K. Bruce and Mr. Stinton for plaintiff, contended that there was an obstruction, and that whether defendants had a right of way or not, they ought not to have obstructed the road. If plaintiff had not restrained them immediately, there might have been a repetition of the nuisance, and then plaintiff would have been told that he was barred by his former acquiescence.

The Vice Chancellor,—There is no doubt in this case that the acts of the defendants were wrongful, and that the deposit created inconvenience, by which I mean considerable obstruction to the plaintiff's wharf, so that it was very difficult to approach it. This is clear from the affidavit of plaintiff, who states that the timber could not pass, and that his horses and carts were prevented turning, so that there was a material obstruction. The defendants were conscious of this, for they took steps to remove the scaffolding, &c., immediately upon notice; and then it is said that the plaintiff ought to have awaited the removal instead of immediately applying for an injunction: but he had a right to apply, especially as it was evidently intended to bring in a much larger quantity. The plaintiff thus stopped any possible ulterior injury. All the clay was not cleared away when the bill was filed, so plaintiff was not bound to consider whether it would take time to remove it, especially as the deposit was made in two days, but five or six were occupied in removing it. The injunction must stand, and the motion be dismissed with costs. A. A.

MEETING OF SCIENTIFIC SOCIETIES.

Civil Engineers' Institute every Tuesday evening.

Royal Institute of British Architects, Monday, May 7, at three o'clock, Annual General Meeting of Members only. Monday evening, May 21.

Architectural Society, Tuesday evening, May 8.

PARLIAMENTARY STANDING ORDERS.

The House of Commons on the 26 ultimo appointed a Select Committee, "to consider the standing orders of the House of Commons, relating to private bills, and to compare them with those of the House of Lords, with the view of assimilating as much as possible the standing orders of both Houses."

We believe we were the first who called the attention of the Public to the evils existing in the present standing orders of the House of Commons; our observations on the subject will be found in our first number, for October, and subsequently, in our third number, for December. As we stated then, we had no objection to the standing orders of the House of Lords; we considered them framed in the best spirit; and we are still of the same opinion. We sincerely hope that the Lords will not consent to alter one of their standing orders, but compel the Commons to frame their orders conformably to them. And we do hope that there will not be any more silly attempts to frame standing orders, to prevent speculation and gambling on the Stock Exchange. If they are not allowed to have railway shares to speculate upon, they will always have others; as at the present time, they have Asphalte and other companies starting up daily.

PROGRESS OF RAILWAYS.

The Hull, Lincoln, and Nottingham Railway.—This line is now in a fair way of going on; it has been taken up with great spirit on the line, and numerous applications have been made for shares. The importance of the undertaking is greater than might at first be thought; but upon a reference to a map, it will be at once seen that this line will be most important, as it will complete a diagonal chain of railways through England, connecting the German Ocean with the Bristol and English Channels, and forming the nearest route from London by forty-five miles to the important port of Hull. It will also be twenty-five miles nearer by this line from Birmingham and all the great manufacturing towns in the midland counties to Hull, thus offering a rapid and cheap communication for the conveyance of the goods from our manufactories for all the northern countries of Europe. The line for many miles will be formed on the present surface, with no other expense than levelling the land, and laying down the rails. Lord Yarborough, and all the great landholders on the line, give it their hearty support, and several of them have offered to take the value of the land in shares: others have offered timber and stone, to be paid for in the same way. This is a spirit which ought to be encouraged by Parliament, and we hope will form an example for other landowners coming forward thus liberally on other lines, instead of driving them off their estates.

The Northern and Eastern Railway.—After a long period of inaction and doubt, the works upon the London and Cambridge Railway have commenced, and are now proceeding with activity. The point selected for the first operation of the contractor (Mr. Mackintosh) is Tottenham Mills, and the facility with which the first mile and a half has been nearly finished in the short space of three weeks, demonstrates the advantages which the company will enjoy, in point of cheap and rapid construction, as compared with all others. The survey between Broxbourne and Royston is now nearly concluded, and the negotiations for the land will immediately commence. In the parish of Edmonton a violent opposition is to be offered to the company's surveyor by the owners and tenants of certain large farms intersected by the line, who have sent in claims of a most preposterous nature, and thus compelled the company to have recourse to so fortunate a circumstance.—*Hertford Paper.*

Manchester and Sheffield Railway.—The works are to be forthwith commenced.

Southampton.—Our railway is progressing rapidly, and it is calculated that twenty-five miles of it from London will be open on the 1st of May.—*Hampshire Telegraph.*

To London in One Day.—In consequence of the opening of the greater part of the London and Birmingham Railway, the journey from Liverpool and Manchester to London can now be performed in one day. Passengers who go from Liverpool and Manchester by the Grand Junction trains at half-past six in the morning, will arrive at Birmingham soon after eleven, and will have from that time till one o'clock for dinner or business, when the trains leave for London, where it is expected they will arrive soon after eight o'clock:—and passengers leaving London by the half-past seven trains will arrive in Liverpool or Manchester between nine and ten in the evening. The arrangements for the conveyance of the mails by the London and Birmingham line, we understand, will not be completed before the 7th of May, after which day the London bags will reach Liverpool about ten o'clock in the morning.

Great North of England Railway.—The works of this undertaking at Northallerton and its vicinity are now in full progress; the foundations of the first bridge, connecting the old Roman camp (over which the railway will have to pass) with the Castle Leazes, were commenced on Tuesday last.—*Leeds Intelligencer.*

Midland Counties Railway Company.—A special general meeting of the proprietors was held at the Bull's Head and Anchor Hotel, Loughborough, on Friday, the 23rd of March, for the purpose of ratifying an agreement entered into by the directors, with the North Midland Railway Company. The chairman, James Oakes, Esq., having explained the object for which they were assembled, considerable discussion ensued, and the utmost unanimity of opinion, as regarded the agreement with the North Midland Company, which is now definitively settled, prevailed. We understand that agreement to be, that the North Midland Company bound themselves for the term of seven years to transfer all their traffic southward from Derby to the Midland Counties Railway; with a power, however, to put an end to it, should any other company, for three successive months, carry their passengers and goods at lower rates, and in the same average time.

Gloucester and Birmingham Railway.—The company is now proceeding vigorously with this important undertaking, and the line between Cheltenham and Worcester bids fair to be completed within the time specified. The contractor who has taken the portion from the depôt to Maude's Elm is advancing rapidly with the works under his direction. Since the severe frost has left us, the workmen have made visible progress at Alstone, and the road which runs in deep cutting under the present Gloucester road, has been sunk down several feet, for a considerable distance through the land near Mr. Prescod's residence. The depôt is to be placed on the Cheltenham side of the Gloucester road not far from the junction of the present Leckhampton tram-road. The company, it is understood, have come to an arrangement with the Cheltenham and Swindon Company respecting the formation of the line hence to Gloucester, and the opposition raised by them to the Swindon amended act, is we believe in consequence withdrawn.—*Cheltenham Looker-on.*

Sheffield and Rotherham Railway.—The directors have let the different works of the Sheffield station to Messrs. L. G. Reed and Co., of Broomhall Street, builders; and the Rotherham station to Mr. Blackmoor, of that town; both are to be completed by the 1st of July next. The entrance for passengers to the Sheffield station will be by three handsome iron gateways—one for carriages and two for foot. They will be erected at the corner formed by the junction of Saville Street with the Occupation Road (now part of the Wakefield turnpike) and will face directly up the Wicker, forming a bold and interesting object of view from that spacious street. A commodious shed, about 200 feet long and a corresponding width, supported on metal columns, will cover the passenger-station and booking-offices. The entrance for goods is proposed to be near the present gateway to Mr. Alfred Sorby's house at Hall Carr. The gate to the coal yards will be a little further on. Here there will be a staith so constructed that coals may be transferred from the railway with the greatest facility. The station in Westgate, Rotherham, will be provided with a shed of similar construction to the one at Sheffield. The branch to connect this railway with the North Midland at Masbrough, has been let to Mr. John Stephenson, the contractor for the main line.

Sheffield and Rotherham Railway.—The works at the railway are proceeding with great rapidity, and are expected to be so far completed in August next, as to enable the directors to make a formal opening of the same. In addition to the locomotive engines previously ordered, Messrs. Bingley and Co., of Harper street Foundry, in this town, have just received orders from the company for engines to be ready shortly after the opening.

Chester and Crewe Railway.—Mr. Stephenson states that the line may be opened to the public in eighteen or twenty months after breaking ground. Satisfactory arrangements have been made with almost all the landowners through whose property it will run.—*Midland Counties Advertiser.*

The Maryport and Carlisle Railway.—At a meeting of the directors held at Maryport, on Saturday, the 17th ult., Sir Wilfrid Lawson, Bart., of Brayton Hall, in the chair, the construction of the first portion of the railway, comprising that part of the line between Maryport and Gilcrux, was contracted for. Mr. Irving is the contractor for the excavations, and Mr. Nelson, of Carlisle, for the erection of the bridges. The work has thus been fairly embarked in, and will, no doubt, be commenced immediately.—*Cumberland Pacquet.*

Sheffield, Ashton under-Lyne, and Manchester Railway.—A meeting of the Board of Directors of the above undertaking was held on Wednesday, the 18th ult., at Penistone, the Right Hon. Lord Wharncliffe in the chair; at which Mr. Vignoles, the eminent engineer of the Company, was instructed to proceed immediately to stake out the line of railway, and prepare for putting the works into active operation. It is expected that the Manchester end of the line, running by Ashton, Hyde, and Mottram, as far as Glossop, will be completed at an early period, by which a large and profitable passenger traffic will be brought upon the railway, whilst the heavier works near the summit are in progress. From the arrangements in contemplation, there is no doubt that the whole of the line will be completed within the time fixed by act of Parliament.

The North Union Railway.—This great undertaking is in rapid progress towards completion, and notwithstanding the many unforeseen and unfavourable circumstances that have, from time to time, retarded the works, the whole line will probably be opened towards the end of August. At the Preston, or north portion of the line, from 120 to 130 men are employed on the bridge, including 40 masons; and not fewer at the cutting beyond the valley of the Ribble. The whole number employed on this part of the line, and at the Preston terminus in Fishergate, and the quarries, &c., may be about 600. Last year, when in full operation, the number engaged on the same ground, averaged from 800 to 850 men; but the works are now considerably narrowed, both in stone work and excavation, so that the same number could not be advantageously employed. Little more than two arches of the bridge now remain to be thrown over. The two on the north side already span, with solid stone, their respective chords; the third is rapidly closing over the centre; the fourth is on both sides considerably above the spring; and the fifth, which is on dry land, will be commenced within a short time; so that the roadway may be available by the period stated, leaving the parapet walls only to be built to complete the whole structure. The "sheeting" planks, or (in Lancashire phrase) the "lagging," has already been removed from the centre on the north side, and the arch stands as firmly as if it were hewn out of the solid rock. The bridge, when finished, and cleared of the vast quantity of timber that now encumbers it, will present a very beautiful and light appearance, notwithstanding the immense weight of the stone, and, when closely viewed, the massy nature of the structure. The Wigan end of the railway is also in a forward state, and the damage occasioned by the flood in autumn last, at Pinnock, is about to be repaired by the construction of a strong wooden bridge.—*Preston Observer.*

Great Western.—It is intended to open the Great Western Railway as far as Maidenhead, a distance of twenty-six miles, on the 1st of June next. The Company have already got upwards of fifty carriages ready for passengers.

The works of the Southampton Railroad are making rapid progress. The first twenty-four miles out of London, being the nearest point on the road to Guildford, will be open to the public on the 14th of May, and upwards of forty miles will be completed early in the autumn.

The London and Birmingham Railway.—On Monday 9th ult., a farther portion of this great line at the London end, and the first portion at the other extremity, were opened to the public. The London train started from the station at Euston-square shortly after seven o'clock in the morning, and arrived at Tring, the former temporary terminus, in somewhat less than two hours. From this point, the line inclines more to the northward, leaving Cheddington and Mentmore to the left. The first three or four miles of the new portion are carried by cuttings to a considerable depth through a loose sandy soil; and thence along a rich agricultural valley to Leighton Buzzard, which is left about half a mile to the right. At this station there is a tunnel of nearly a furlong in length, being the only one which occurs on the newly opened portion of the line. The present terminus is at Denbigh Hall, a little hamlet about two miles beyond Fenny Stratford, on the high road to Stoney Stratford; which is here crossed, at an elevation of about thirty feet, by a lofty and elegant viaduct. The train reached Denbigh Hall at twenty-five minutes past ten—the last stage, 16½ miles long, having been accomplished in fifty minutes. The day was uncommonly fine; and along the line, particularly the newly-opened portion, the crowds were immense, every village and hamlet pouring out its inhabitants, who greeted the novel and extraordinary visitor, as it passed along, with loud and repeated cheering. At Denbigh Hall, the whole population of the surrounding districts appeared to have congregated; and, in default of better accommodation, there being no regular inn or hotel in the neighbourhood, the itinerant vendors of sandwiches, rolls, pies, and other dainties, reaped an abundant harvest. A large tent was erected close to the station, in the event of unfavourable weather; and here the passengers for Birmingham were transferred to coaches and other vehicles, which had been provided

for that purpose. At the Birmingham extremity, the interest excited by the proceedings of the day was, if possible, still more gratifying. The first train started precisely at three minutes past nine, and as it cleared the station, was greeted with hearty cheers by immense crowds of persons who had assembled on every point which could command a view of its progress. At thirteen minutes past nine, the train passed the Yardley viaduct, moving through a beautiful country at a rapid rate—this portion of the line being on an inclination of 1 in 330 inches. Soon after leaving Yardley, a passing view of the village and church of Coleshill was afforded to the left, while the village of Sheldon lay in the valley on the other side. After leaving Sheldon, the train passes Partington, the seat of the Earl of Aylesford. The house or park is not, however, seen from the line, lying at least a mile and a half to the left. At twenty-two minutes past nine, the train crossed under the Coventry turnpike-road, having now accomplished about eight miles of the journey, at the rate of four-and-twenty miles an hour. Passing Bickenhill, which lies to the right, a momentary view is obtained of the spire of the church, as also of the village of Hampton-in Arden. After passing this point, a distant view of the village of Meriden, on a pleasant hill, is obtained to the right, with Barston also on the right. The long embankment of about two miles, after passing Hampton in-Arden, though still on an inclined plane, was crossed with much caution. On reaching the deep cutting at the village of Barkswell, the speed was considerably increased, previous to arriving at which the nearest turnpike-road to Kenilworth is passed, the village, with its celebrated ruins, lying about five miles to the right. After leaving this point, the train proceeds through fertile pastures and well wooded land, and it was not a little amusing to observe the cattle scampering, "tails erect," across the fields, evidently not a little surprised and perplexed at this invasion of their own domain. As the train approached Coventry, numbers of persons lined the embankments on both sides of the road, and the various bridges crossing the line. The train reached the station, eighteen and a quarter miles from Birmingham, precisely in fifty minutes. The station lies to the south side, about a quarter of a mile from the town, at which the train remained six minutes to set down and take up passengers, after which it proceeded on its journey to Rugby. Every elevated point, for two or three miles, from which a view could be obtained, was crowded by multitudes of spectators. The works seem to be progressing rapidly at this portion of the line, where great difficulties had to be overcome, if we might judge from the great depth of the cuttings, and the rocky nature of the ground through which the line runs. From Coventry to Rugby few points of attraction present themselves to the eye of the traveller—"town, village—none are on his track." The general aspect of the country, however, with its rich pasture and undulating land, presents a most pleasing feature, until the train reaches the village of Church Lawton, which lies a little to the right, and a good view of which is obtained from the line. At thirty-two minutes past ten the train reached Rugby, at which place omnibuses and coaches were provided for conveying the passengers to Denbigh Hall. On the return of the trains they were received on entering Birmingham with a salute of twenty-one guns (12-pounders) belonging to the Proof-house. The line may now be said to be open; as passengers are conveyed between Denbigh Hall and Rugby (a distance of about thirty-five miles) by stage-coaches, under a contract entered into by the Company with Messrs. Chaplin and Horne, the eminent coach-proprietors. The line appeared in very excellent order, and was in many parts quite equal to any existing rail way. The stations are nearly complete, particularly the splendid terminus at Birmingham. The buildings here are on a truly magnificent and extensive scale, and when finished will cover an area of about twenty acres of ground. This, however, will comprise a spacious enclosed yard, and stores for warehousing goods, and a large engine-house, capable of holding sixteen engines, with their tenders. At the entrances to this building are two immense tanks, which, when filled, contain two hundred tons of water, supplied by the Birmingham Waterworks Company. There is likewise on this area a beautiful range of booking-offices, with separate waiting rooms at either end, for the passengers by the first and second-class carriages. In addition to these buildings, there is a noble edifice in course of erection at the main entrance to the station, intended as a general office for the meetings of the Directors, and a suite of rooms on the ground-floor, which is set apart for refreshments to the passengers. One of the most striking features at the grand station (which is not more than three parts of a mile from the principal coach-offices and hotels), is the magnificent shedding, supported by elegant pillars, erected by Mr. Joseph Bramah, of Pimlico, the extreme lightness and beauty of which excites general admiration. It is capable of covering not less than sixty carriages, and is built on the same plan as that at the Euston square terminus, but is much more spacious. We understand that the Commissioners of Birmingham intend to clear away several of the narrow and filthy streets in the immediate neighbourhood of the station, forming a grand thoroughfare to the centre of the town; and from the spirit with which the plan is taken up, there is every reason to believe that it will be conceived and executed in a spirit worthy of the body with which it originates, and the great undertaking which called it into existence. To work the seventy miles of road now opened, the Company have already at their command about twenty six powerful engines—a supply of steam power which, there is little reason to doubt, will obviate much of that inconvenience, and prevent many of those accidents, which have marked the working of the Grand Junction line. Availing themselves of the hints which these mishaps have suggested, the Directors have likewise a numerous and effective body of police, who are placed under the direction of an active, experienced, and intelligent superintendent. The men on this establishment have been carefully selected—they are dressed in a green uniform, are remarkably respectful in their behaviour, and are placed along the whole extent of line, almost within hail of each other, so that the slightest obstruction on the rails is immediately detected, and should accident or interruption occur to the trains passing up and down, the intelligence can be conveyed to the next station with a rapidity outstripping even the powers of steam.—*Railway Times.*

ENGINEERING WORKS.

Jetty at Waterloo Bridge.—It is in contemplation by the proprietors of Waterloo Bridge to erect a jetty from the second or third arch of Waterloo Bridge, on the Somerset House side, for the accommodation of passengers who may be desirous of landing there from the steam-boats. The convenience of the plan is obvious, and the public will no doubt avail themselves of the opportunity.

A capacious wet dock is immediately to be constructed a short distance east from the village of Grangemouth. Three hundred labourers will be engaged to execute the work. A number of men are at present employed in deepening the Carron, from Grangemouth to its junction with the Frith, which will afford a safe passage to vessels of any burden. These improvements, when completed, will greatly promote the trade and shipping at Grangemouth, which for some time past has rather been declining.—*Glasgow Constitutional.*

Deal.—It is proposed to erect a commodious pier, for landing and embarking passengers by steam-boats. Sir John Rennie has made a very able report on the project.

Falmouth Harbour.—The inhabitants of this town and neighbourhood having entered into a subscription to deepen the water in the inner harbour at their own expense, measures to accomplish this desirable object (by which means ingress and egress will be obtained at all times of tide for the large class sailing packets and steamers) have been already commenced. The committee of management are about petitioning the Admiralty for the loan of a steam-tug or mud-boat to assist in the undertaking.

Blackfriars Bridge.—The report of the committee was presented to the Court of Common Council on the 13th ult. It stated that the sum of 10,000*l.* was required to prosecute the repairs of the bridge, in addition to the 20,000*l.* already expended in that undertaking, and being part of the 60,000*l.* which the Bank had agreed to advance to the city upon the occasion. The report recommended that the sum required should be granted. Mr. Anderton was very desirous to know whether any one could say when it might be expected the repairs would be completed? He was convinced that a great many felt interested in the matter. Mr. Jones (of Bishopsgate ward) said, in the absence of the chairman, that the committee were doing all in their power to induce the contractor to finish the work, and that the contractor, he believed, was also exerting himself to the utmost. It was, however, impossible to say that the whole undertaking would be perfected before the expiration of a couple of years; for, unfortunately, there was great difficulty in procuring stone adapted to the structure. The court might depend upon the active labours of the committee, the engineer, and the contractor. The report was then agreed to.

NEW CHURCHES.

Staffordshire.—Two new Churches are being built under the sanction of Her Majesty's Commissioners for Churches; one at Upper Gornall and the other at Tifton. Robert Ebbells, Esq., is the Architect for both churches.

Middlesex.—Another new Church is to be built in the parish of Islington, under the joint direction of Messrs. Inwood and Clifton, Architects.

Middlesex.—A new Church is to be erected in Spicer-street, Mile-end New Town, under the direction of T. L. Walker, Esq.

Runcorn New Church.—The sum of 2,800*l.*, we understand, will complete this beautiful and sacred edifice, &c.; and we hope to hear of some good friend to religion and our venerable church establishment enrolling his name among the best benefactors of mankind, by endowing the elegant Gothic structure which is rising into view, to adorn and bless the enterprising little town of Runcorn, with its 8,000 inhabitants. The church is expected to be ready for consecration in the course of two months.—*Manchester Courier.*

PUBLIC BUILDINGS AND IMPROVEMENTS.

The workmen have commenced their labours in Westminster Abbey, preparatory to beginning the arrangements for the approaching coronation of her Majesty, by removing many of the seats and wood-work in the chapel of the Abbey.

Stafford House.—The grand gallery will extend between 300 and 400 feet, and will be a perfect *chef-d'œuvre.* The great banqueting-hall will occupy the whole of the northern side of this mansion, the gallery the eastern, and the drawing-rooms the western and southern. All these apartments will be on the first floor, and it is supposed the mansion will not be finished before the close of the year 1840.—*Morning Post.*

Freemason's Hall.—His Royal Highness the Duke of Sussex, on Wednesday, 11th ultimo, inspected some recent improvements which have been made by Mr. Hardwick, under the authority of his royal highness and the grand lodge of Freemasons, in their splendid hall in Great Queen-street.

Scott's Monument.—The long-continued discussion as to the design of the monument to Sir W. Scott, in Edinburgh, has terminated in favour of the architectural monument by Mr. Kemp, combined with the statue by Mr. Steel, recommended from the first by the sub-committee.

A quadruple row of elms, forming three distinct malls, have just been planted with much taste and judgment at the eastern end of Hyde Park, and will, in a few years, add greatly to the beauty of that favourite resort.

The Royal Exchange.—On Tuesday, April 3, the first day's sale of the materials of the Royal Exchange took place. It produced nearly 2,000*l.* The porter's large handbell, (rung every day at half-past four P.M., to warn the merchants and others that 'Change ought to be closed,) with the handle consumed, valued at 10s. was sold for 3*l.* 3s.; the two carved griffins, holding shields of the city arms, next Cornhill, fetched 30*l*; the two carved griffins, holding shields of the city arms, facing the quadrangle, 35*l.*; the two busts of Queen Elizabeth on the north and south sides, 18*l.*; and the two busts of Queen Elizabeth on the east and west sides, 10*l.* 15s.; the copper grasshopper vane, with the iron upright, was reserved by the committee; the alto-relievo, in artificial stone, representing Queen Elizabeth proclaiming the Royal Exchange, 21*l.*; the corresponding alto-relievo, representing Britannia seated amid the emblems of Commerce, accompanied by Science, Agriculture, Manufactures, &c., 30*l.*; the carved emblematical figures of Europe, Asia, Africa, and America, 110*l.* The sale of the remainder of the materials, &c., it is understood, will take place shortly.

The Nelson Monument.—A meeting was held, March 26, at the Thatched House Tavern, St. James's-street, for the purpose of forming a permanent committee to carry into effect the proposal for erecting a monument to the memory of the great Nelson. Amongst those present were Admirals Fleming, Sir Thomas Hardy, and Sir Thomas Troubridge, Captain Dickenson, Captain Jones, and Captain Codrington. Admiral Sir George Cockburn took the chair, and stated the object of the meeting. He stated that he had received a number of names of influence to form an excellent committee. He should request that Mr. Scott, the secretary, do read the list of those who had consented to attend; and if gentlemen present should, after they had heard the names read, think that any ought to be added, they would be at liberty to propose

them. When the committee had been completed he would say a word about their future chairman. Mr. Scott then read the list, which contained the names of the Dukes of Sussex, Cambridge, Buccleuch, and Hamilton, besides a large number of the nobility and gentry. Among the latter were the names of the Chancellor of the Exchequer, Sir R. Peel, the Sheriffs, and Sir Peter Laurie. After the names of Lord Byron, Sir James Shaw, and others, had been added, the committee was appointed, and the meeting adjourned. The committee have since advertised for designs for this monument, to be sent in, by the 30th of June next. We trust that the profession will come forward to compete for the design in a manner worthy of the occasion ;—*England expects every Architect to do his duty.*

FOREIGN INTELLIGENCE.

A bridge is about to be thrown over the Rhine at Dusseldorf.

Steam Navigation.—The American House of Representatives have voted 100,000 dollars (24,000*l.*) to the heirs of Fulton, the original founder of steam navigation.

The winter palace of the Emperor of Russia is to be rebuilt precisely as it was before, only with some additions that had been proposed and approved by his Majesty, and with some changes in the arrangement of the inner apartments.

Projected Railway in New South Wales.—A company is about to be formed for the purpose of making a railroad from Sydney to Yass, a township on the Morum bidgie river, about 200 miles south-west from Sydney, in the direct line to Port Philip.

Cathedral Church.—A meeting took place at Sydney the 24th October, the Bishop of Australia in the chair, when 4,000*l.* towards the building of a cathedral church at Sydney was subscribed. It was supposed that at least 20,000*l.* would be available for this purpose.—*Australian Papers,* Nov. 9th.

America.—A great design is on foot by the New York legislature, to authorize a loan of 28 millions to prosecute the works of internal improvement now in progress. If such a measure passes, the moneyed men here will have a fine field for the exercise of their philanthropy.—*Morning Herald.*

The King of Greece has appropriated a sum of 120,000 drachmas to the construction of a new lazaretto at Syra, of sufficient magnitude to contain convenient accommodation for upwards of 200 persons, each having a separate lodging. It will be composed of two buildings, comprising magazines, apparatus for fumigation, baths, &c., and a residence for the inspector.

Steam Engines.—The governor of Milan has issued a notice, dated the 18th of January, stating that an imperial decision of the 25th November, 1837, has fixed for the present the duty upon the importation of steam-engines necessary for the government railroads, at 1 per cent. This duty will be afterwards increased 1 per cent. every following year, until it reach 5 per cent. This decision, however, is not to prejudice the arrangement that every machine unknown in the kingdom, and imported for the first time, is to be exempt from all duty. This decision entered into execution on the 1st January, 1838, and the duty is paid exclusively at the principal custom house.—*Mining Journal.*

Belgium.—Besides the theatre at Ghent, which is now in progress, and will, when completed, be an exceedingly spacious edifice, Roelandt, one of the most eminent architects in Belgium, is engaged upon several other buildings, among which are the new Depôt for merchandise, and Palace of Justice at Antwerp, and the Town-house at Awst.

Milan.—Voghera, of Milan, already known to the public by his work on the Antiquities of Pavia, is about to bring out a splendid publication illustrative of the Arco della Pace at Milan, erected from the designs of the late Marchese Cagnola, and after the Barriere de l'Etoile at Paris, one of the most stupendous monuments of its class in modern times.

Railroad from Strasburg to Basle.—We learn from Alsace that the railroad from Strasburg to Basle has been commenced with great spirit; a considerable portion of the land has been purchased; some of the embankments are far advanced, and everything leads to a fair expectation that this line will be completed before its rival, on the other side of the Rhine, is begun, notwithstanding the vote of the chambers of Baden.

Subterranean Travelling.—The line of railway between Lyons and St. Etienne, the largest manufacturing town and richest coal district in France, is only thirty-four miles in length; yet such is the unevenness of the country, and so great has been the anxiety of the engineers to preserve as complete a level as possible, that there are actually no less than twenty tunnels between the two termini! One of these is a mile in length, while another, which is half a mile in length, is carried under the bed of a river which crosses the line.—*Mechanic's Magazine.*

Internal Navigation of France.—The committee charged to examine the bill relative to this subject, will soon finish its work. Of four canals proposed by government, the committee have adopted two—that from the Marne to the Rhine, and that along the banks of the Garonne. They are both considered by the committee as political and international lines. The first will complete the navigation from Havre to Strasburg, and will ensure the circulation of produce from many departments in the east whose manufacture and commerce have no outlet. This line is the most important to France, as the German Powers are occupied with the junction of the Rhine and Danube, which, by means of a projected canal, will open a communication between the Atlantic and the Black Sea. The second of these canals, in effecting the junction of the Mediterranean and Atlantic, will ensure, in case of a maritime war, great advantages to the south of France.—*French paper.*

French Railroads Bill.—The committee on this bill has come to a conclusion unfavorable to the plan of confiding to the government the execution of any other than the great lines; and has recommended that even those shall in preference be intrusted to private companies, unless the latter decline to undertake them. This decision of the committee was adopted by a considerable majority, on the ground of the delay likely to attend the execution of the lines by government, and also on account of the considerable expense in which the ministerial system would involve the chamber.—*Paris paper.*

STEAM NAVIGATION.

The "Great Western" Steam Ship.—This superb vessel left her moorings at Blackwall, on her voyage to Bristol, at eight minutes past six on Saturday morning, March 31, and at twenty-two minutes past seven passed Gravesend, the engine working beautifully, and the progress of the vessel highly satisfactory. At a quarter past eight o'clock a strong smell of burning oil was perceived to arise from the felt clothing of the upper part of the boilers, which soon after took fire, and from the quantity of dense smoke arising from it caused much apprehension; it was, however, soon extinguished by the powerful means on board of supplying a large stream of water. The vessel having during this time been brought to, off Leigh, an examination took place by Messrs. Maudsley and Field, who were on board, who found that the workmen had improperly felted the boilers close up to the base of the chimney, and that the composition of oil and red lead with which the felt was stuck on, had consequently fired, smoked, and finally burst into flame. The origin of this unpleasant occurrence having been thus satisfactorily ascertained, all further cause of alarm was allayed by its immediate removal. Neither boilers nor engines had sustained the slightest injury. The vessel remained on the Chapman Sands until the flood tide lifted her, when she proceeded on her voyage, and arrived in the port of Bristol about six o'clock on the following Monday evening, having completed her voyage round from London, being 670 miles, in 58½ hours, 6½ of which she was detained by her accident, thus clearing very nearly 13 miles per hour. She came to an anchor opposite the Battery, at the river's mouth. She started from Bristol on Monday morning the 8th ult., with but few passengers. We understand that several who had paid their passage, forfeited the fare when they heard of the accident described above.

On Saturday morning, March 31, at nine o'clock, a new steam-boat, called the "Falcon," belonging to the Eagle Steam-boat Company, made its first trip from Waterloo-bridge to Blackwall and Gravesend.

Two more large steamers are to be built at Chatham dock-yard. They are to be the same size as the Hydra, now constructing in one of the docks of that yard.

The "Royal Adelaide."—We lately had the gratification of visiting one of the finest and largest steam-vessels that ever floated at our quays. She is the property of the City of Dublin Steam Packet Company. The "Royal Adelaide" was launched a few weeks since. We examined minutely every portion of this vessel's nautical architecture, and we can safely affirm that we never saw strength and solidity so beautifully combined with purely artistical taste as we found exemplified in the Royal Adelaide. Her engines are 300 horse power, having the advantage of every modern improvement in steam science; her build combines strength and security. The principal saloon is elegant, airy, and roomy, the private cabins are remarkably convenient, and the splendid manner in which they are furnished would surprise any one unacquainted with the style in which passenger vessels are now fitted up. The arrangements for cargo, for carriages, horses, &c., are also most excellent. She is placed on the Belfast, Dublin, London, Falmouth, and Plymouth station, and her first voyage has been unprecedentedly quick.—*Belfast Northern Whig.*

It is said that the directors of the London and Westminster Steam-boat Company, in order to test the plan so strenuously supported by Captain Basil Hall, have ordered one of their vessels to be fitted up with the wheel at the head instead of the stern.

The iron vessels building on the Clyde, and just on the eve of launching, possess strength, safety, and speed, in a greater degree than those of timber hitherto in use, by being divided into five sections, with partitions as strong as the sides of the vessel; they will not only be safer as regards fire, but in the event of striking on a rock or in collision with another ship; for although one or two of the sections were cut and filled with water, those remaining would maintain the vessel afloat. They are made so as to arrive or depart at even low-water at Glasgow; and should they be employed in the Liverpool trade, the communication between that port and Glasgow *via* the Birmingham Railway will not exceed 30 hours.

Starting of the "Sirius," Steam Packet for New York.—At a few minutes after ten o'clock on Wednesday, April 4, the "Sirius" left Cork and proceeded on her voyage, having on board thirty state cabin, twenty-nine fore cabin, and thirty five steerage passengers; accompanied by the "Ocean" steam-packet, which vessel proceeded to the harbour's mouth, to bring back those ladies and gentlemen who remained on board to see their friends to sea. It is expected to make the voyage in twelve days. The "Sirius" is the property of the St. George Steam Packet Company, and was chartered by them to the British and American Steam Navigation Company. It is intended to make two more voyages to America, until the "British Queen," their splendid new vessel, is ready. We understand the "Sirius" will leave New York on the 1st of May.

We understand that a company has been started in Liverpool, under the name of the "Liverpool and New York Steam Navigation Company," who propose to build steam-ships for the purpose of running between Liverpool and New York.—*Liverpool Standard.*

Two fine steam-packets are to run this summer between Rye and Boulogne. They will sail more than ten miles an hour; the voyage will be performed in about three hours and a half.

Glasgow.—A beautiful steam-ship named the "Tarbert Castle" was launched on the 13th ultimo at Messrs. Hedderwick and Rankin's building-yard, near the Broomielaw quay.

The Clyde.—The competition in the steam navigation on the Clyde this season bids fair to be of rather an animated description, from the number of steamers that are making their *debut* for carrying passengers to and from the various watering-places on the coast. A splendid new steamer, the "Argyle," has been built by Mr. Robert Duncan, ship-builder, Greenock, who has devoted himself to the perfecting of the models of river steamers. From the power of her engines, the "Argyle" will be one of the best and swiftest conveyances to Lochfine. No cost has been spared in the fitting-up of the cabins.

Plan for preventing Concussion with Waggons on Railroads.—Mr. R. Ayre, of the Bridge End, to whose ingenious inventions, connected with railroads, we have had frequently much pleasure in calling the attention of our readers, has communicated to us a plan for preventing concussion of the waggons or carriages, on the sudden stoppage of a train. This plan consists of a *cleet* on the one carriage, say the carriage before, and a curved iron, something like a coach-spring, which by coming under the cleet will brake or stop both the fore and hind wheels, the connexion of the cleet and the curve causing brakers at the other end of the curved iron to produce that effect. The result with a long train must naturally be such as to render the expensive *buffers,* at present employed, comparatively useless.—*Tyne Mercury.*

PARLIAMENTARY PROCEEDINGS.

House of Commons.—List of Petitions for Private Bills, and progress therein.

Those marked thus — are either withdrawn or rejected.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 24TH MARCH, AND THE 26TH APRIL, 1838.

JULIUS JEFFREYS, of Kensington, in the County of Middlesex, Esquire, for "Improvements in Stoves, Grates, and Furnaces."—24th March; 6 months.

JOHN CLARK, the Younger, of Mile End, Glasgow, Cotton Spinner, for "Improved Machinery for Turning; some Part or Parts of which may be made applicable to other useful Purposes."—4th April; 6 months.

WILLIAM ANGUS ROBERTSON, of Peterborough Court, Fleet Street, in the City of London, Patent Agent, for "Certain Improvements in the Manufacture of Hosiery, Shawls, Carpets, Rugs, Blankets, and of other Fabrics. Communicated by a Foreigner residing abroad."—4th April; 6 months.

GEORGE BARNETT, of 40, Jewin Street, in the City of London, Tailor, for "An improved Button, for protecting the thread or shank from friction and wear."—7th April; 2 months.

JOSEPH ROCK COOPER, of Birmingham, Gun Maker, for "Improvements in Fire Arms."—10th April; 6 months.

THOMAS WATSON, of Addle Hill, Doctors' Commons, in the City of London, Mechanist, for "Improvements in Stoves."—10th April; 6 months.

DAVID REDMUND, of Wellington Foundry, Charles Street, City Road, in the County of Middlesex, Engineer, for "Certain Improvements in the Construction and Apparatus of Steam Boats or Vessels used for War or Commercial Purposes."—10th April; 6 months.

EDWARD COBBOLD, of Long Melford, in the County of Suffolk, Clerk; and PETER RICHOLD, the Younger, of the same place, Coach Maker, for "Improvements in the Manufacture of certain Pigments or Paints, or such like Substances."—10th April, 6 months.

WILLIAM FOTHERGILL COOKE, of Breede's Place, Hastings, Esquire, for "Improvements in giving Signals and sounding Alarms at Distant Places, by means of Elastic Currents transmitted through Metallic Circuits."—18th April; 6 months.

WILLIAM BARNETT, of Brighton, Iron Founder, for "Certain Improvements in the Production of Motive Power."—18th April; 6 months.

THOMAS MURRAY GLADSTONE, of Bootle-cum-Linacre, near Liverpool, Chain Cable and Anchor Manufacturer, for "Certain Improvements in Ships' Windlasses, which Improvements are applicable to other Purposes."—21st April; 6 months.

EDWARD COOPER, of Haverton, in the County of Wilts, Clothier, for "An Improvement in the Making or Manufacturing of Soap."—21st April; 6 months.

JAMES TIMMINS CHANCE, of Birmingham, Glass Manufacturer, for "Improvements in the Manufacture of Glass."—21st April; 6 months.

JAMES MACNED, Coach Maker, George Street, Edinburgh, for "An Improvement or Improvements in Carriages."—21st April; 2 months.

MOSES POOLE, of the Patent Office, Lincoln's Inn, in the County of Middlesex, Gentleman, for "Improvements in Manufacturing Carpets, Rugs, and other Napped Fabrics. Communicated by a Foreigner residing abroad."—21st April; 6 months.

CHRISTOPHER NICKELS, of York Road, Lambeth, Manufacturer, for "Improvements in Machinery for Recovering Fibres, applicable to the Manufacture of Braid and other Fabrics."—21st April; 6 months.

ROBERT FINLAYSON, of Regent Street, Cheltenham, in the County of Gloucester, M.D., for "Improvements in Harrows."—21st April; 6 months.

FRANCIS POPE, of Wolverhampton, in the County of Stafford, Fancy Iron Worker, for "Certain Improvements in Machinery for Making or Manufacturing Pins, Bolts, Nails, and Rivets, applicable to various useful Purposes."—24th April; 6 months.

THOMAS VAUX, of Woodford Bridge, in the County of Essex, Land Surveyor, for "Improvements in Tilling and Fertilizing Land."—24th April; 6 months.

SAMUEL WAGSTAFF SMITH, of Leamington Priors, in the County of Warwick, Iron Founder, for "Improvements in Regulating the Heat of Furnaces for Smelting Iron," which Improvements may also be applied to retorts for Generating Gas.—24th April; 6 months.

ALEXANDER HAPPEY, of Basing Lane, in the City of London, Gentleman, for "A New Composition applicable to Paving Roads, Streets, Terraces, and other places, which Improvements are also applicable to the different Purposes of Building, and also in the Apparatus for making the said Composition. Communicated by a Foreigner residing abroad."—25th April; 6 months.

RICHARD GOODWIN, of St. Paul's Terrace, Camden Town, in the County of Middlesex, Coal Merchant, for "An Improved Prepared Fuel."—26th April; 6 months.

NOTICES TO CORRESPONDENTS.

The first communication of R. E. did not come to hand; the second was received too late for notice in our last month's Journal.

We have been obliged to postpone, till our next number, the paper by Philotechnicos, the Antiquarian, a description of Collier's Patent Boiler, and some other communications, in order to clear off our arrears.

The next month's Journal will contain a description and drawings of the Blind Asylum; including the apparatus for warming, cooking, washing, &c.—the whole forming, we hope, a very interesting paper.

We have not received any Drawings explanatory of the *New Invented Steam-Engine*, described in our Journal for March last; the paragraph was copied from a Birmingham Paper.

ERRATA IN LAST NUMBER.

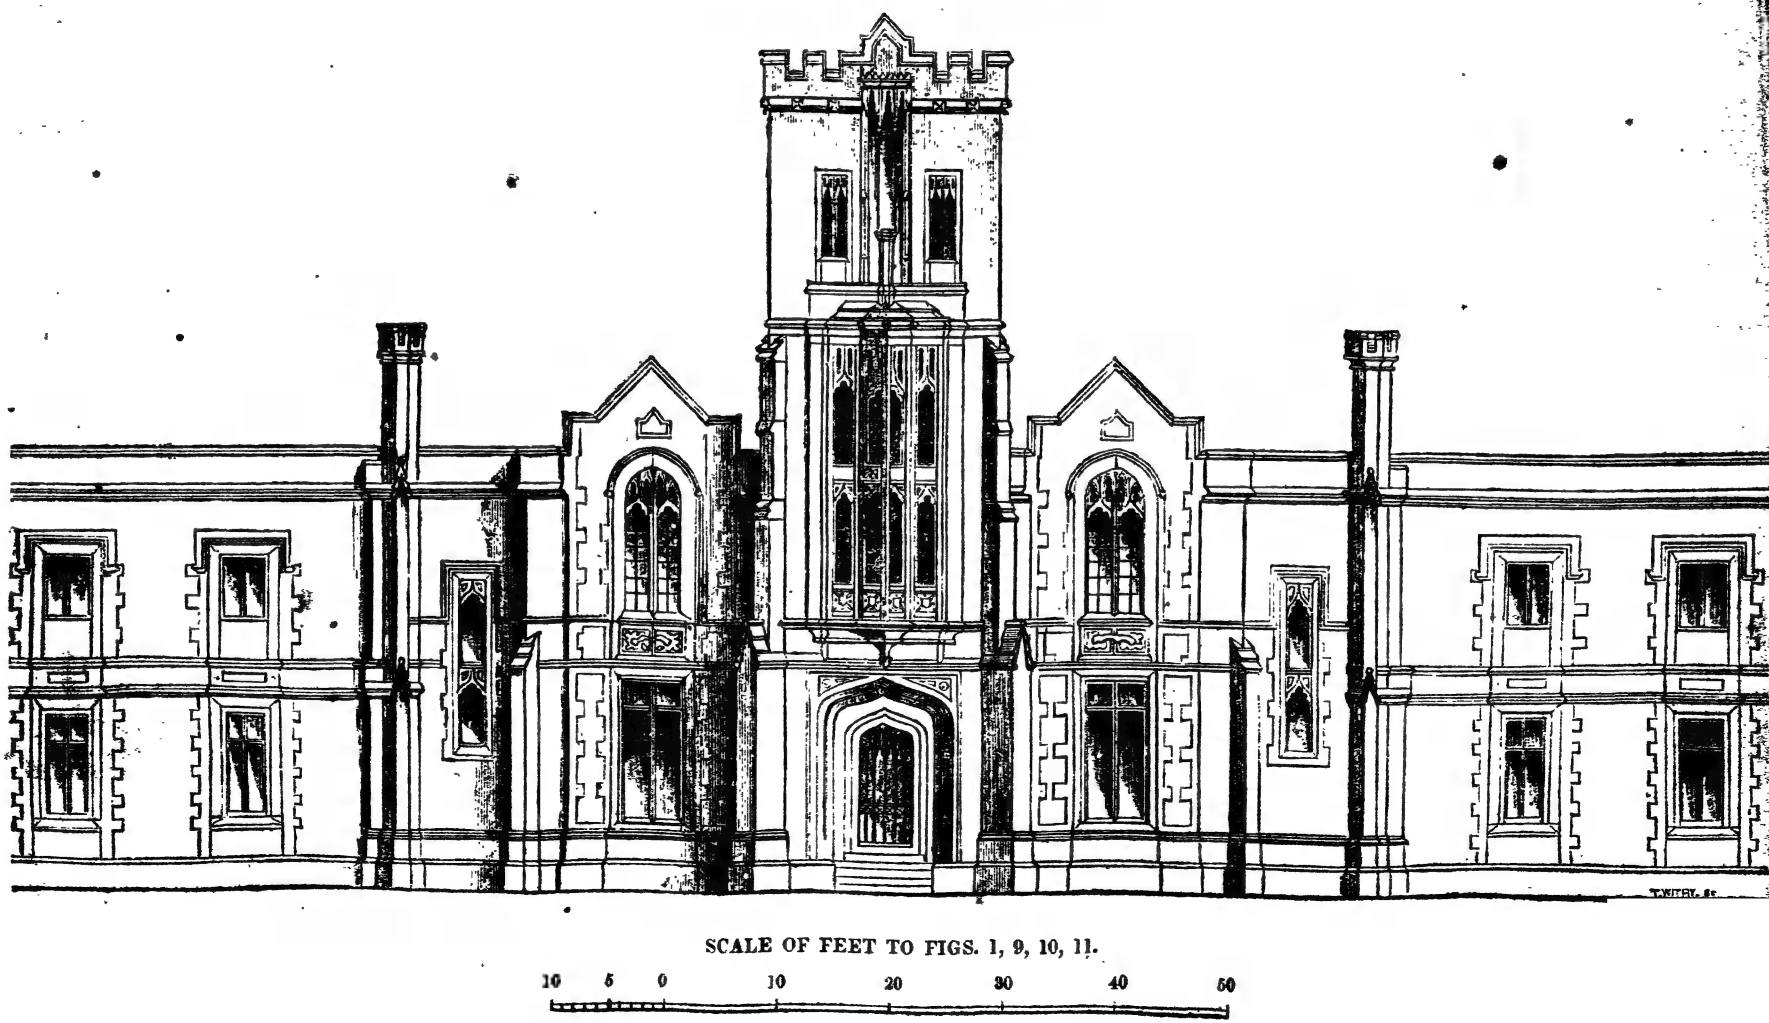
SCHOOL FOR THE INDIGENT BLIND,

ST. GEORGE'S FIELDS.

JOHN NEWMAN, Esq., F.S.A., ARCHITECT.

FIG. 1.—ELEVATION OF THE CENTRE BUILDING.



SCHOOL FOR THE INDIGENT BLIND.

Although this building has attracted very little attention,—has in fact scarcely been mentioned in any way by those who have spoken of contemporary productions of our metropolitan architecture,—it has some claim to notice, if merely on account of its great extent, in which respect it falls very little short of its neighbour, Bethlehem Hospital; its extreme length on the line comprising the fronts of the wings being 550 feet, while that of the other is 569. Whether this silence may not be in some degree attributable to its *out-of-the-wayness* from any fashionable quarter of the town, we pretend not to decide; but certain it is that the building itself does not deserve it. This we think will be allowed even by those whom our wood-cuts now make acquainted with it for the first time; although they show its elevation piece-meal, nor pretend to do justice to the ornamental details, which have not been so carefully attended to as we could wish. We think it but right to state this, lest any inaccuracies and want of spirit observable in the cuts should be imputed to the building itself; and also lest, so judged of, it should not be thought to warrant our favourable opinion of it. There is certainly much happiness of effect as well as novelty, in the diagonal position of the wings, whose fronts, in consequence of being turned thus obliquely, display themselves to greater advantage than they otherwise would do, and at first sight produce an apparent irregularity by no means disagreeable. Their elevations, which are pleasing and in good taste, appropriate in character, simply but judiciously decorated, serve as a counterpoise to the tower and central compartment of the principal or North front, and thus bring the whole into keeping. The abovementioned division of the longer façade is quite of a piece with the end elevations, but treated with greater importance, and on an extended scale. It is exceedingly well composed, and detaches itself effectively from the general line of building, both in its plan and elevation; and owing both to the variety of its outline, and the bold projection of its buttresses, shows itself to advantage even when quite in shade, and before it receives the sparkling lights on its projecting surfaces ere the sun shines fully upon it,—which is only at this season of the year. Yet although there is no want here either of variety or suitable ornament, there is a pleasing degree of unity and soberness. It is full, without being crowded and crammed; and regular, without being formally or monotonously so; for which it is in no small degree indebted to the two staircase windows, which differing so much from the others both in their proportions and position, occasion what may be termed a symmetrical irregularity, the irregularity relatively to one side alone, being counterpoised by the same irregularity in a corresponding situation on the other side of the centre. The rest of this front is treated quite subordinately to its centre, yet not so as to clash violently with it, but rather in such manner as to give it full effect. Did the design terminate with these lateral parts, then indeed the centre tower might be considered somewhat too ornamental, and too strongly marked; but as we perceive that its character is resumed in the front of the wings, the objection that might otherwise arise is obviated. The exterior of the building is of white brick, with Park spring stone dressings and ashlar coins to the windows, and the tower, bay windows, and gateways, are entirely of the latter material. It was erected from the designs of J. Newman, Esq., the architect of the Roman Catholic Chapel, Finsbury Circus.

We hope that the plans of the building which we have given, aided by the explanatory references appended to them, will render the general arrangement of the various parts intelligible. The block plan of the ground floor will show the size and general form of the building; while the enlarged drawings of the centre and wings on both floors, will exhibit the disposition of the rooms in them. We will now give a glance over the whole interior of the edifice on both floors, noticing particularly the principal rooms, and whatever seems most to deserve attention. But first we must observe, generally, of the interior, that it corresponds well in style and character with the exterior; while no unnecessary or superfluous ornament has been introduced, we detect nothing of niggardliness in the design or want of solidity in the execution. The general arrangements are well adapted to the purposes of the establishment, and calculated not solely for its present extent, but for its prospective enlargement. And the whole has been constructed in so substantial a manner, as to promise to be a lasting monument to the munificence of the supporters of the Institution.

On the *first floor* in the centre, is the Chapel or Music room A, fig. 6; it is divided into four compartments by archways which support the tower. In the centre compartment to the front, immediately under the tower, is placed the Organ; on each side of which are ranged seats for the inmates of the establishment. The remainder, forming the largest compartment, is occupied by seats for the public; and in the centre, opposite the organ, is placed the reading desk. The ceiling is flat, formed into panels by moulded ribs with bosses at their intersections, the ends next the walls resting on brackets supported by corbels. The whole is grained in imitation of oak, and has a very pleasing effect, harmonizing well with the character of the building. Adjoining the chapel, are rooms for the linen or wardrobe; and bed rooms for the assistants who are in charge of the dormitories at night. The Dormitories occupy the whole length of the building over the work rooms D and C, as shown in the block plan fig. 2; and more at large at E, figs. 6 and 7, and M, figs. 6 and 8. They attract the eye of the visitor, as remarkable for their large size, and light and airy appearance. Additional height is gained by taking in part of the roof, which is ceiled as shown in fig. 9. The walls are not plastered, but the brick-work is worked fair and coloured; and a stop or fillet is nailed all round the floor and scribed to the walls instead of skirting. The beds are arranged in a double row, divided at the head by a quarter partition boarded on both sides, and about five feet high, running along the centre of the room. A section of this division will be seen in fig. 9; as also one of the iron rods rising to the roof, by which it is kept steady in its place. This arrangement of the beds, we consider admirable, as placing them out of the reach of the draft from the windows. In the Western Wing at the end, are two more dormitories for the boys; and also Linen rooms. In the Eastern Wing is a suite of apartments for the Superintendent of the institution. It contains also two smaller dormitories for the girls; and the girls' Washing room fitted with numerous washing basins, each furnished with a supply of water, and a waste pipe and plug.

On the *ground floor* is the Kitchen, N, fig. 3; most appositely placed between the two dining rooms O and P. It is spacious and lofty; and lighted from the top by a Lanthorn light, the position of which is shown by the dotted parallelogram in the centre, fig. 3, and its form is exhibited in the section, fig. 10. It is furnished with sculleries, R R, one on each side, and all requisite offices. The cooking apparatus is of the best construction, and on a scale adequate to the magnitude of the demands upon it in so large an establishment. It was planned and executed by Mr. Stephen, of Great Russell-street. On the side next to the girls' dining room, O, fig. 3, are placed the roasters, &c., in a recess built for their reception. They will be seen in fig. 10; but very imperfectly, owing to the smallness of the scale. The two side compartments are fitted with Rumford's roasters, heated by the fires of the stewing stoves which occupy the centre compartment. Of these stoves there are three, the middlemost being used when the roasters are not required. In a corresponding recess on the opposite side of the kitchen, stands the range, furnished with back boiler for the supply of hot water to the scullery and kitchen. Over the range is a smoke-jack; and on each side are copper boilers. The Dining rooms, O and P, fig. 3, are furnished with a double row of tables and benches running lengthwise along the rooms; to these are added in the boys' room, P, a supplementary single row along the back wall, with a carver's table in the corner. The remaining portion of the centre building, is occupied by the Hall, Committee room, and apartment of the Matron and Assistants, who are thus advantageously placed for the exercise of control and superintendence over the whole establishment. Adjoining the centre building are the Work rooms: that for the boys is on the right; it is 165 feet long, 25 wide, and 15 high: that for the girls is on the left; it is 147 feet long, corresponding in its other dimensions with the boys' room. The walls of these rooms are not plastered, but finished as described above in the case of the dormitories. In the Wings at each end, there are smaller work rooms; and entrance gateways leading to the grounds. That on the left contains also a counting-house, and a warehouse; and adjoining is the shop, for the sale of the various articles manufactured by the inmates. In the right-hand Wing we find also the boys' Washing room, Y, fig. 5, which exhibits much ingenious contrivance. Round the room are arranged pewter washing basins, each fitted with a supply pipe, and a waste pipe with moveable plug. Along the room are fixed two long tables, with drawers to hold the boys' dressing apparatus: at each end is a large towel mounted on a roller, which is set transversely to the tables and supported by long iron rods. Between these tables is situated a long double trough for feet-washing, with seats on each side between it and the tables. A board about three inches wide and guarded by ledges, runs along the whole length in the middle, and serves as a common soap dish for both divisions of the trough. This trough is of wood, lined with lead; it is supplied with cold and hot water, the latter from the furnace in the adjacent room S. The water is carried off by waste pipes in the bottom, fitted with plugs. The Play-grounds L and I, fig. 2, will when cleared and levelled, be ample in size, and in every respect adapted to their important purpose;—important, as the blind are generally found to need all possible inducements to take the requisite quantity of exercise. The long covered walks, G and H, are likewise admirably suited for places of exercise in wet weather. Their roofs are supported by elegant iron brackets let into the walls, as shown in fig. 9.

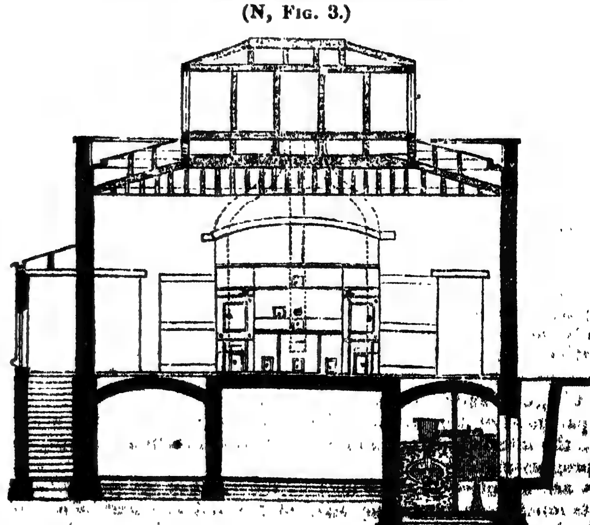

FIG. 11.—ELEVATION OF EASTERN AND WESTERN WINGS.

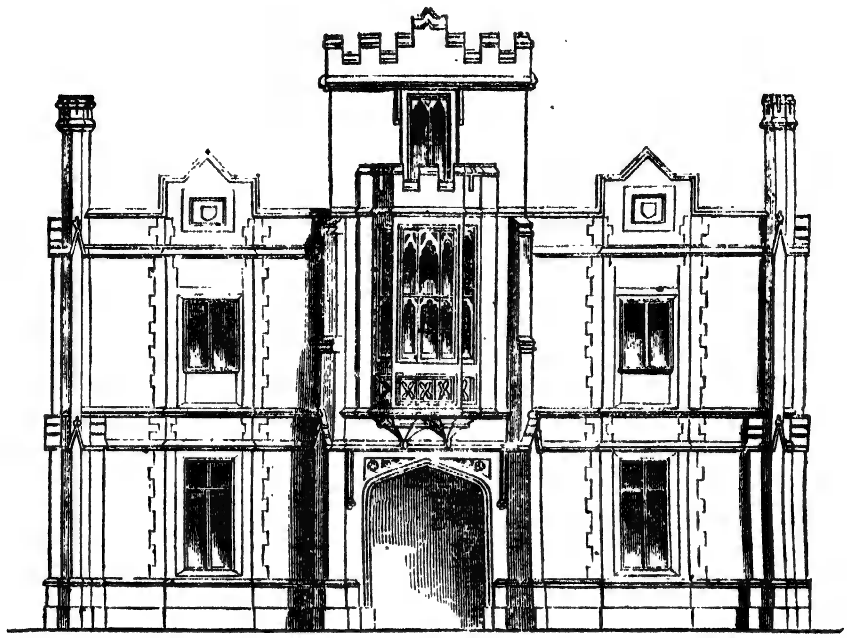
(F and E, Fig. 2).



The ventilation and warming of this building is very complete: the method adopted, is that of Messrs. Price and Manby. We shall give in our next number a drawing of the apparatus, and a description of the arrangement of the flues for the warming of the several rooms. The letters *w* and *v* which will be seen in various parts of the plans, indicate the apertures for the admission of warm air, and for ventilation: the course of the current of air from the stove, is indicated by the arrows.

In choosing this building as the subject of the present article, it was of course our main object to exhibit the architectural character of its elevation, and its various excellent and ingenious internal arrangements. Still, we cannot be content to be altogether silent respecting the nature and the objects of the Institution for which it has been erected. We confess that we see with peculiar satisfaction the forms of architectural beauty and the contrivances of mechanical skill, thus applied to a purpose which we believe to be truly noble and excellent. And we doubt not that our readers will agree with us, that our notice of the building would be incomplete without a short sketch of the nature and objects of the Institution. This we supply mainly from the last report, published in March.

The School for the Indigent Blind, was instituted by private benevolence in 1799. Beginning on a very small scale, it was in the course of a few years sufficiently encouraged, to enable its directors to purchase a part of the land which they at present hold, and to erect the buildings in which the school was till lately conducted;—in which indeed till the new building is completed, its operations are still partially carried on. In 1826, the directors and friends of the Institution were incorporated, under the title of "The President, Vice-President, Treasurer, and members, of the School for the Indigent Blind." The qualification of members is a donation of ten guineas, or an annual subscription of one guinea; a larger amount entitling to a proportionately larger number of votes for the admission of Candidates. The continually increasing support of the public towards this institution, enabled the Corporation in the spring of 1834 to commence the erection of the present building. The Western wing and the Centre were the parts first begun, and they have been for some time in use for the boys' department of the school. The Eastern wing is very nearly finished; the internal fittings and the few last external touches, are rapidly progressing.

Pupils are admitted to the school by the votes of the subscribers; applicants must be between the ages of ten and 25; and none are admitted who have a greater degree of sight than will enable them to distinguish light from darkness. They remain in the school till they have acquired a sufficient knowledge of their trade, which is generally acquired within four or five years, but which necessarily depends on the capacity of the pupil: they then leave the institution, with a portion of their earnings, and a set of tools for their respective trades. They are then able, according to their several abilities, to earn from six to 28 shillings a week. The girls are taught the spinning of fine and coarse thread, the manufacture of a peculiar kind of sash line which is much approved by builders, the netting of bags and reticules, and fine basket making: they are also employed in knitting and needle work. The boys are taught shoe-making, basket-making, and mat-making in various materials both fine and coarse. A large assortment of the articles manufactured at the school is always kept for sale; they will be found both useful and elegant. We may mention here, that the pupils regularly receive as pocket-money, a part of their earnings.

The religious and moral instruction of the pupils is, further, carefully attended to. Such instructions have usually been given orally, in the education of the blind; but we are happy to perceive that the system successfully adopted in America and elsewhere, of teaching them also to read by the touch from embossed books, has been introduced with some success here. We are also glad to find that the type employed is the usual Roman capital, not any arbitrary character. On this subject, and on the objections made to the new practice of of teaching the blind to read for themselves, we quote the following passage from a recent traveller in America.

"The common letters are used; and not any abbreviated language. I think this is wise; for thus the large class of persons who become blind after having been able to read, are suited at once; and it seems desirable to make as little difference as possible in the instrument of communication used by the blind and the seeing. It appears probable that, before any very long time, all valuable literature may be put into the hands of the blind; and the preparation will take place with much more ease if the common alphabet be used, than if works have to be translated into a set of arbitrary signs. It is easy for a blind person, previously able to read, to learn the use of the raised printing. Even adults, whose fingers' ends are none of the most promising, soon achieve the accomplishment. An experiment has been made, on a poor washerwoman, with the specimens I brought over. She had lost her sight eight years; but she now reads, and is daily looking for a new supply of literature from Boston, which a kind friend has ordered for her.

It will scarcely be believed that the objection to this exercise which is most strongly insisted on, is that it is far better for the blind to be read to, than that they should read to themselves. It seems to me that they might just as well

be said about persons who see; that it would save time for one member only of a family to read, while the others might thus be saved the trouble of learning their letters. Let the blind be read to as much as any benevolent person pleases; but why should they not also be allowed the privilege of private study? Private reading is of far more value and interest to them than to persons who have more diversified occupations in their power. None could start this objection who had seen, as I have, the blind at their private studies. Instead of poring over a book held in the hand, as others do, they lay their volume on the desk before them, lightly touch the lines with one finger of the right hand, followed by one finger of the left, and, with face upturned to the ceiling, show in their varying countenances the emotions stirred up by what they are reading. A frequent passing smile, an occasional laugh, or an animated expression of grave interest passes over the face, while the touch is exploring the meaning which it was till lately thought could enter only through the eye or the ear. They may be seen going back to the beginning of a passage which interests them, reading it three or four times over, dwelling upon it as we do upon the beauties of our favourite authors, and thus deriving a benefit which cannot be communicated by public reading.

One simple question seems to set this matter in its true light. If we were to become blind to-morrow, should we prefer depending on being read to, or having, in addition to this privilege, a library which we could read for ourselves?"*

It is with much satisfaction that we find the conductors of this institution expressing an intention to increase their stock of books for the blind (already containing the whole of the New Testament,) by the addition of further portions of Scripture, as well as other useful and instructive books. We wish they would add, entertaining also; for the blind have with the exception of sight, all the capacities of human nature; they have also, all its wants. We would give them all the means of mental and moral improvement which we possess by the use of books; nor would we deny them that innocent and delightful recreation which we derive from works of imagination;—perhaps even more necessary in their case than in ours.

Music, as a means of amusement and improvement, is not neglected. Pupils who show a natural inclination to it, are especially instructed in it, with a view to thus earning their livelihood. We were present at a music lesson given to one of the boys on the organ; and were much pleased with the manner in which he played the Hallelujah Chorus, exhibiting alike his own taste for his art, the excellence of the instrument, and the fitness of the room for musical purposes. We were pleased also with the playing of some of the girls, whom we found practising on the piano. And in the workshops too, a song was started now and then, in which any or all joined at their pleasure, giving a cheerful and happy appearance to their work, which we shall not soon forget.

The school contains at present 60 boys and 62 girls: five more of each sex will be admitted in July, at an election for which there are 49 candidates. The new buildings are calculated to accommodate 100 boys and 100 girls; and as we have seen, will speedily be entirely finished. We trust that public support will go on as heretofore tending more and more towards this excellent institution; and that its managers will soon be able to report their rooms full, and their list of candidates much reduced. We beg to suggest that in one respect this Charity is free from the objection to which some others are liable,—the tendency to produce more misery than they relieve, by offering temptations to imprudence. It most effectually removes the evils attendant on blindness;—but none would, either by design or through carelessness, become blind as a qualification for admission.

We add, in the Corporation's own words, their invitation to the public to come and see for themselves. We hope they will find our descriptions of the building tolerably complete and accurate: we are sure they will find our praises of the Institution itself fully justified by their own observation.

"Such is the nature of the School for the Indigent Blind; a charity which, in no slight degree, improves the condition and increases the comfort of those whose claims to compassion and assistance cannot be disputed. All persons desirous of observing the extent, to which the situation and faculties of the blind are capable of improvement, may satisfy themselves by visiting the School, which will be readily shown to them; they need not be apprehensive of seeing anything which can hurt their feelings;—they will not find the pupils (of a class hitherto considered as doomed to a life of sorrow and discontent) sitting in listless indolence, or brooding in silence over their own infirmities; but they will behold them animated in their amusements, during the hours of recreation, and cheerfully attentive to their work, during those of employment.

The pupils may be seen at work between the hours of ten and twelve in the forenoon, and two and five in the afternoon, on every day except Saturdays and Sundays."

* Retrospect of Western Travel, Vol. III., pp. [illegible]

PREVENTION OF THE DRY ROT.

Dry rot is a misnomer. This disease in timber ought to be designated a decomposition of wood by its own internal juices, which have become vitiated for want of a free circulation of air. If you rear a piece of timber newly cut down in an upright position in the open air it will last for ages. Put another piece of the same tree into a ship or into a house where there is no access to the fresh air, and ere long it will be decomposed. But should you have painted the piece of wood which you placed in an upright position, it will not last long; the paint having stopped up its pores, the intercepted juices have become vitiated, and have caused the wood to rot. Nine times in ten wood is painted too soon. The upright unpainted posts in the houses of our ancestors, though exposed to the heats of summer and the blasts of winter, have lasted for centuries; because the pores of the wood were not closed by any external application of tar or paint, and thus the juices had an opportunity of drying up gradually. If then you admit a free circulation of the air to the timber which is used in a house (no difficult matter) and abstain from painting that timber till it be perfectly seasoned, you will never suffer from what is called dry rot. And if the naval architect, by means of air holes in the gunwale of a vessel (which might be closed in bad weather), could admit a free circulation of air to the timbers; and if he could also abstain from painting or doing with turpentine, &c., the outer parts of the vessel till the wood had become sufficiently seasoned, he would not have to complain of dry rot. I am of opinion, that if a vessel were to make three or four voyages before it is painted or done with turpentine, &c., its outer wood would suffer much less from the influence of the weather than it usually suffers from its own internal juices, which cannot get vent on account of artificial applications to the pores. But still the timber would be subject to the depredation of the insect. To prevent this effectually, Mr. Kyan's process must absolutely be adopted to secure wood from what is called dry rot, in places where a free circulation of air cannot be introduced. I consider Mr. Kyan's process perfectly unexceptionable. The long arrows which the Indians use in Guiana are very subject to be eaten by the worm. In 1812 I applied the solution of corrosive sublimate to a large quantity of these arrows. At this hour they are perfectly sound, and show no appearance that the worm has ever tried to feed upon them.—*Waterton's Essays on Natural History.*

SMOKY CHIMNEYS.

It has often occurred to us that one very common cause of smoky chimneys, where no apparent reason can be discovered, arises from the practice of using boys to sweep them, and thus the sin against humanity is partly punished by a large amount of continuous annoyance. For a flue to draw well, it is essential that there should be only two openings into it—one at the bottom and the other at the top. Now chimney flues are divided from one another by single courses of bricks in width, or half bricks, as it is technically termed. Those flues are built with lime mortar, which is an absurdity in the outset, as the heat of the fire restores the mortar to the state of quick lime, which falls out in powder, and leaves gaping chinks for misdraught between the bricks, destroying the continuity of the flue. To provide in some measure against this evil, the practice is to coat the inside of the flue with a composition of lime-mortar with cow-dung, called "pargetting." This is, in fact, a luting to make the flue air-tight. The climbing boys, by frequent ascents, break the luting away, and the chimney, opening into chinks, produces an imperfect draught. This is an evil for which there is no remedy, except rebuilding the chimney. Were it the practice to use iron tubes built into the thickness of the walls, or better still—as more economical of heat—to introduce hollow iron columns upon the face of the wall, covering them in the apartments with perforated screen partitions, the great source of evil would cease, and the still greater evil—the crime—the degradation of humanity would cease also.—*Note to an able Critique upon Dr. Arnott's Stove, in the Lon. and West. Review, by "J."*

ANTI-OXYDATION OF METALS.

We have been favoured with an inspection of several specimens of copper and iron, prepared by Mr. Wall, with a view to the prevention of the oxydation of metals. We have also inspected a vessel (The "Mary") in Her Majesty's service, now lying in Woolwich Dock-yard, which has been sheathed with Mr. Wall's prepared copper. We have further seen a certificate signed by the Vice-Admiral and other Officers of Sheerness Dock-yard, stating "that the surface resists all action by acids, and that they are of opinion that it will resist any chemical action of the salt water. The test the preparation was subjected to was Nitrous Acid, which the surface resisted without any sensible change."

We have ourselves tested specimens of the prepared copper and iron with very strong Muriatic Acid and Nitrous Acid, neither of which produced any apparent change on either specimen. We consider the discovery of great national importance, as the process may be applied to the surface of all metals at a very trifling expense; we shall make farther inquiries and watch the progress of this invention, and lay before our readers in our next number such information as we may be able to collect respecting it.

REVIEWS.

The Steam Engine; its Invention, and an Investigation of its Principles, for Navigation, Manufactures, and Railways. By THOMAS TREDGOLD. Enlarged and edited by W. S. B. WOOLHOUSE, Esq., F.R.A.S. Part I., with 60 Plates. London: John Weale.

(*Second Notice.*)

IN the present edition, the original text of Tredgold has been reprinted, with corrections by the Editor, particularly in the mathematical formulæ. The additional matter, liberally provided with the view of bringing up the arrears of scientific knowledge on this subject to the present time, is given in the form of an appendix, as we stated in a former number. We proceed to notice in order, the various papers which it contains;—first observing however of the whole, that it embodies a vast quantity of information very valuable to the practical engineer: and that the reading of it has given us much pleasure and satisfaction.

No. 1, consists of observations ON MARINE BOILERS, by Mr. J. Dinnen, Assistant Engineer in her Majesty's Dockyard, Woolwich. From his situation, the author evidently enjoys great advantages for the prosecution of inquiries connected with his subject: and his manner of treating it, especially the amount of valuable experience which he brings to bear upon it, plainly shows that he has made good use of his opportunities of observation. Finding it totally impossible by mere extracts to give an adequate idea of the various matters contained in this paper, we subjoin an abstract of it, pretty fully comprising its subjects: and a few extracts have been introduced to show the author's own style of expressing his observations.

Mr. Dinnen begins with a refutation of the common opinion that the water of the Mediterranean is salter than that of other seas. From various experiments which are detailed, it appears that all sea water (except where exposed to peculiar influences, such as the influx of rivers, &c.) may, for practical purposes, be considered as containing an equal quantity of salt. From experiments made some years since by Messrs. Maudsley and Field, it is ascertained that sea water boiling under the usual low pressure of two pounds and a half on the square inch, will arrive at 226 degrees Fahrenheit in twenty-four hours, at 230 degrees in forty-eight hours, at 232 degrees in sixty hours, &c. At this period it contains $\frac{11}{33}$ of its bulk of salt, saturation takes place, and the deposit of salt on the surfaces of the boiler begins. Sufficient water was supplied during the experiment to supply the evaporation: in the instance alluded to, sixteen gallons per minute. Mr. Dinnen has frequently repeated the experiment and derived corresponding results. As the evaporation goes on, it is evident that the specific gravity of the water increases by the accumulation of the salt: and to raise an equal quantity of steam, continually increasing heat must be applied. Thus the thermometer becomes a practical register of the density of the water; and it may readily be adapted to the boiler for this purpose. The tendency of the continual evaporation being to leave in the boiler more and more salt, it becomes necessary to adopt some means of removing the accumulation; or rather, of removing the brine before it begins to deposit the salt. For this purpose Messrs. Maudsley and Field introduced a *brine pump* to remove from the lowest part of the boilers at each stroke, a certain proportion of the water supplied by the feed pump. In the experiment before alluded to, four-fifths of that water being required for the supply of steam, one-fifth was removed by the brine pump. By this means, the temperature (before shown to be an index of the specific gravity) was maintained regularly at about 226 degrees, six degrees below the point at which the deposit of salt begins. This brine pump Mr. Dinnen recommends for use in land engines, where fresh water is not to be had: at sea it has been superseded by the process of *blowing out.* Of the employment of this latter process, several instances are detailed: in one voyage to the Mediterranean and back, a portion of the water was blown out every two hours: the thermometer was maintained at 215 degrees, and no deposit formed. The same temperature was maintained uniformly in the voyage of the "Atalanta" and "Berenice," sent out by the East India Company, and the delay of blowing out completely every three or four days (the order for which is still in force in the navy) avoided: and this without any ill effect on the boilers.

Mr. Dinnen's experience goes decidedly against the introducing of iron into a copper boiler, as a specific against deposit or chemical action; the only effect appears to be the destruction of the iron, without any advantage. The action of the water alone, appears to have little or no influence on the copper; an incision made in a boiler with a chisel, remained unaltered at the end of three years. It is only when calcareous matter is allowed to accumulate, and adhere to the flues and fire places and even to fill up the water ways, requiring forcible mechanical means to remove it, that damage ensues. Accumulations of soot, salt &c. in the flues are to be guarded against as very destructive to the boiler. The salt comes from water which forces its way through the numerous insignificant apertures which it is impossible entirely to guard against by any care in the construction. The mixture of salt and soot corrodes the copper of the boiler very rapidly; as appears from the fact of copper being precipitated from it on the iron floor of the engine room, where in one instance it lay nearly two days. The defects alluded to, existing exclusively in the angle pieces and rivets of the bottom of the flues, have been completely removed by a fillet of Parker's or Roman cement, applied so as completely to enclose the angle pieces. This method may of course be applied also in iron boilers: but is recommended only in cases where mechanical skill has failed. Copper boilers appear more subject to decay from this cause than iron ones: bottom flue plates three-eighths of an inch thick have decayed in twelve months. The remedy is, to keep the flues well swept, and perfectly dry when not in use. The sulphate of lime begins to deposit sooner than the salt to crystallize: 220 degrees has been esteemed the limit (under the pressure of the atmosphere), but Mr. Dinnen (12) finds 215 degrees to be the maximum, and indeed subsequently (20) states that sulphate of lime *will* deposit and indurate at any temperature from 212 degrees upwards. The remedy here, as before in reference to the deposit of salt, is to blow out periodically and regularly. And we hope so simple and plain a remedy needs only to be forcibly stated to ensure its being attended to; it is, in fact, but one case out of the million where great damage and danger may be averted by timely precaution;—so true is the old adage, that "prevention is better than cure." To facilitate the process of blowing out, some useful hints are given respecting the construction and arrangement of the blow off cocks and pipes; and Kingston's safety-valve and pipe is strongly recommended as a means of guarding against danger from the large holes with which the bottoms of steamers are perforated. To the neglect of these precautions alone, Mr. Dinnen refers the serious damage often sustained by boilers even in a single voyage, and not to the intensity of the draught, which when well regulated, he views as a decided advantage. Iron boilers are more subject to blister and crack than copper, which is readily accounted for by the different modes of manufacture adopted for the two metals.

We have now followed Mr. Dinnen pretty closely through his first eight pages, and have we hope gleaned information interesting and useful to our readers. They will however have probably felt with us one defect which detracts in some degree from the great excellence of his paper;—the want of any very clear and well marked arrangement. Valuable pieces of experience, and useful remarks on the same or kindred subjects are separated by other observations, likewise useful, on other important subjects;—as indeed appears in our abstract. They are well worth attention as they stand: we merely suggest that they might be more readily referred to and more profitably read, if more systematically arranged. The latter part of the paper, entitled "Additional Observations and General Remarks," is more clearly arranged, being divided into certain general heads, and its minor divisions distinguished in the printing by the use of capitals and italics. Even here however, there occur occasionally remarks which might perhaps have been arranged better in other parts. We proceed to give some account of this latter portion of Mr. Dinnen's paper.

Where there are more boilers than one, much damage frequently arises from the side pipes communicating between their lower parts, becoming choked up. When this is the case, the blowing out cleanses only one of the boilers. Where each boiler is furnished with a cock for the purpose, it is not safe to blow out all at once; so that, severally they are not relieved often enough. Several examples are given, of the length of time which has elapsed between the necessary repairs of iron and copper boilers in constant use; they are all greatly in favour of the copper ones. And it is recommended that boilers in use beyond a limited period, regulated by the incrustations, should be scaled once a month while actively employed: this would not take more than two or three days, and would render violent measures unnecessary.

On the Construction of Copper Boilers.—Mr. Dinnen appears decidedly as the apologist of copper boilers; and he gives some hints on their construction which may help to bring them more into use again. The destruction of the bottom plates of the flues has been universally the cause of their abandonment, even when they were very sound in other parts. To remedy this defect the author recommends that care be taken to make the rivet holes in the lower angle irons coincide exactly with those in the plates, and the rivets properly fit the holes; and, in short, that the whole be done in an exact and workman-like style. This is absolutely necessary when working in copper; *seeps* which in iron would speedily be stopped by the na-

tural operation of rust, go on in copper indefinitely, working their way like worms in wood. So also, respecting the joints of the plates with the angle irons. For the protection of the lower part of the flues, exposed to the action of the salt which will come through notwithstanding all precautions, a coating of Roman cement is recommended, it having been found very useful even when the damage was partially done. The same care should be taken in the construction of the bottom and lower parts of the shell of the boiler as has been recommended in the case of the flues. The funnel should invariably be of iron, stepping on a cast iron ring fitted to the top of the boilers; for experience has proved that copper in this situation is rapidly corroded. The practice of throwing water into the ash-holes is condemned as tending to destroy the bottom plates, often while all the rest of the boiler is sound. To conclude, copper boilers are strongly recommended, notwithstanding their greater expense at first; if the necessary precautions be taken, they will require much less mending,—an important consideration in long voyages.

Circulating Pipes, Dampers, &c.—The side pipes between the boilers are often inaccessible, being concealed by the coal-boxes; so that they are liable to be left uncleaned and become choked up. They ought to be examined *at least* on the return from every voyage. Further means of circulation should also be provided; there ought to be free communication above the flues, and as near the surface of the flues as possible. The "Flamer" has lately been furnished with two tiers of connecting-pipes, the upper ones three inches below the level of the flues. Experience has proved, that it is unnecessary to cut the passages between the joining boilers sixteen or eighteen inches above the flues, as was once thought advisable. The best way of disposing the parts of a boiler is, in Mr. Dinnen's opinion, to have the two, three, or more parts running the whole length fore and aft;—each distinct. Each should have a damper of its own; as the damper fitted to the chimney will be sure to be carried away with the funnel, in case of its being by any accident swept overboard; and the ship thus exposed to the risk of fire. Each steam-pipe should have a communication-valve; or a valve should be fitted on top of the steam-chest of each boiler, where they join the common steam-pipe; so that any of the boilers may be used independently of the rest. Several important advantages are pointed out as likely to flow from this arrangement. Fuel might be much economized by coating the boilers, steam-pipes, and cylinders with non-conductors; which has been done to some extent in the navy. The following hints also respecting the firing are useful:—

> *Economy of fuel* on long voyages has not, I am prepared to say, met with the attention it deserves: stokers consult their own convenience; and as long as they keep *plenty* of steam flying off to waste, they are seldom called to account [illegible] myself, I have found the greatest difficulty in obliging them to [illegible] the fires uniformly. In a gale of wind, and then only, when the labour was little on the fires, and when it became a consideration with every one, both on deck and below, to eke out the means of arriving at the destined port in safety, the fires were minutely attended to, and the fullest effect obtained at the least possible expense: a few *clinkers* only, and *no ashes*,—which should never, in iron boilers, be allowed to remain longer than two hours in the ash-pits, or in contact with the boilers on the stoke-hole plates,—were thrown overboard twice in twenty-four hours, when such discipline was observed, and this with the Welch coal. How much greater would the gain be *at all times*, if the oppressive heat, which drives the fireman from his quarters now, were removed, so as to permit him to dispose a *less* portion of fuel to a wonderfully increased advantage? These considerations are by no means visionary; the people in Cornwall understand them well, and profit thereby to a considerable amount. I have, on a summer's day, found it sensibly cooler in an engine-house closed, containing a cylinder eighty inches in diameter, and ten feet stroke, while the steam-gauge indicated thirty-four lbs. per square inch on the safety-valve, than I experienced without: the boiler-house nearly the same. Is not economy in fuel as loudly called for in marine engines, without reference to stowage, health, and the labour and dirt of shipment?

The best number and arrangement of furnaces is considered, and their size discussed: it is recommended to make them not less than three feet wide, as the fires act destructively on the sides of narrower ones; nor more than six feet long, as that is about the greatest manageable length for the stoker. In the arrangement of plates in the furnace, perpendicular seams should be avoided, as liable to injury. It is very usual to employ iron plate of too great thickness for the furnace: in the largest boilers, three-eighths is quite thick enough for the plates above the bars. But the lower parts of the sides, and the bottom of the fire-place, should be thicker. The up-take should also be thicker, and frequently cleaned, and coated with some anti-corrosive. Various hints are given for securing the top and sides of the boiler from dirt and corroding influences; and warnings thrown out, against the use of wood too near the heated surfaces. The error of making the water-ways too small, is pointed out; Mr. Dinnen recommends never to make them less than four or five inches, and even more when they come between the fire-places. Some useful hints are given respecting scaling, and the necessity of having due time allowed, insisted upon. The flues need never be larger than to allow convenience for repair and sweeping. In blowing off, there is a danger of leaving the boiler deficient in water, which must be carefully guarded against. A "detector-pipe" is now used in some vessels, to give notice of this danger; a description of which is given, as also of a contrivance by Mr. Kingston to prevent the accidental leaving of the cock open. Copper-floats, with an index in front of the boiler, are recommended in preference to the glass water-gauge, for showing and regulating the height of water within. It is recommended to make the reverse valves full four inches in diameter, and to keep them always clean and ready to act;—points too seldom attended to. Some useful hints are given respecting the fixing of boilers, tending to their preservation. A suggestion is also thrown out, that in war it will be found useful to have the boilers distinct, in case of one being disabled by a shot.

Remarks on Atlantic Steam Navigation.—Under this head we find principally observations on economy of heat, and saving of fuel. Waste from cylinders and boilers for want of coating, is here illustrated by detailed accounts of experiments, and calculations founded upon them. And extracts are given from the author's journal of a Mediterranean voyage, to enforce his rules for the economizing of fuel. Some useful hints are suggested respecting the sweeping of flues, which appears to be less frequently necessary on long voyages than might be supposed; here too, we have facts obtained by observation brought forward in proof of the author's views. The remarks under this head are very valuable, especially from the facts which they record; we only regret that they were not brought forward in proof of what the author advanced in the earlier part of his paper, on the several subjects of waste by radiation, economy of fuel, &c. This section ends with a hint to charge the boilers with fresh water as often as possible; and with the following short summing up of Mr. Dinnen's views of the prospects of steam navigation for long voyages:—

> The only question of a vessel's continuance at sea, for any consistent period of time, is—the fitness of the engines,—the conduct of the boilers,—and the quantity of fuel which she can stow, compared with her consumption. Consequently the probable capacity of a steam-vessel for the Atlantic or any other voyage, so far as her machinery is concerned, may be fairly estimated before she finally sets out for her destination; the contingencies of weather on the particular service being duly considered.

Paddle Wheels.—Mr. Dinnen has remarked, that the parts of the wheels below and near the water line are subject to much more rapid decay in the Mediterranean, and between the Tropics, than elsewhere. This he attributes mainly to the great heat speedily evaporating the water left by the spray, and thus depositing brine and salt, which speedily corrode the machinery. He considers however, that another powerful agent is at work in this destruction: having observed that marine vegetation, barnacles, and lime are very abundant in the neighbourhood of the paddles, while the rest of the bottom is clean, he concludes that this effect is owing to the galvanic influence of the copper sheathing, which is thus protected at the expense of the paddle-wheels. And this conclusion he has found confirmed by the examination of all her Majesty's steam-vessels returning from the Mediterranean and West Indian stations, which constantly exhibit the same appearances. To remedy this defect, Mr. Dinnen proposes to apply to these particular parts, protectors on Sir Humphrey Davy's principle. And having thus only to contend further against the influence of the sea-water before alluded to, he gives some good hints on the construction of the paddles, and the following simple receipt for a protecting varnish:—

> I have found coal tar, heated by a shot plunged in to drive off the naphtha, when applied to such parts as were chafed, or otherwise left unprotected, to be a very good varnish for paddle wheels; the wheels being examined, and covered in such places on the arrival from *every* voyage: by this treatment, a paddle wheel may resist the action of the sea water for several years.

The next paper, No. II. entitled A Form of Steam Journal, is by Thos. Baldock, Lieut. R.N., K.T.S. It contains some useful remarks on the necessity of keeping a proper record of the operation of the engines in all steam vessels; and furnishes a form for the journal, with directions for the regular insertion of all matters which it is desirable to register in its columns.

No. III. is on the Motion of Steam Vessels; its author is P. W. Barlow, Esq., C.E. After remaking that different circumstances require different constructions of the machinery, river navigation, and long and short sea voyages demanding each their peculiar adaptations; Mr. Barlow enters on a comparison of the different kinds of *Paddle Wheels* at present in use.

> The power of the steam engine, when employed in propelling vessels, being applied through the medium of a fluid by the reaction of the paddle wheel,

there results an unavoidable loss of a large portion of the power of the engine. To construct a wheel by which this loss will be reduced as much as possible, is an important point to be aimed at, and many inventions have appeared with the view of effecting this object. We therefore propose, in the first place, to enter into a comparison of such of these wheels as have come into general use, and to endeavour to illustrate the nature of their action.

The construction of the ordinary paddle wheel is so simple as scarcely to need description: it consists of a circular framework of iron, supporting paddles at equal distances round the rim, and radiating from the centre: these wheels are attached to a strong shaft passing through the vessel, to which the motion of the engine is conveyed by cranks placed at right angles to each other: the revolution of the floats or paddles in the water creates a resistance upon them, and the corresponding reaction on the main shafts produces the force by which the vessel is propelled.

It is evident, that in this construction of wheel two kinds of lost power must exist: first, by the action of the paddle being oblique, or at an angle with the horizontal direction of the vessel in every position except the vertical one, by which of course only a portion of the power exerted on the paddle becomes effective; and secondly, by the receding of the wheel in the water necessary to create a resistance equal to the force applied by the engine. This may perhaps be best illustrated by the case of a locomotive engine: if the friction between the wheel and the rail be such that the former does not slip, the motion of the carriage will be the same as that of the circumference of the wheel; the whole power of the engine is employed in propelling the carriage, and consequently there is no lost power: but if the friction be not sufficient, the wheel will slip back some quantity; the same steam will be consumed in the revolution of the wheel, but the carriage will not be advanced as before, and there will be a loss of power proportional to the skidding or receding of the wheel: so also in a steam vessel all that the centre of pressure actually goes back in the water, or all that its circumferential velocity exceeds that of the vessel, is comparatively lost power; the expense of the steam being proportional to the former, and the effect to the latter.

This source of lost power must of course exist in all paddle wheels, whatsoever their construction, from the resistance being created in a fluid; but that kind first described being owing entirely to the radiation of the paddles, a great number of inventions have been proposed to remedy the evil, by causing them to keep a vertical position by the aid of machinery during their progress through the water. These wheels, although they possess much superiority over the ordinary construction in a sea, or where the wheel is deeply immersed, by obviating the loss of power from the obliquity of action and back water, are subject to evils of another description; and it is a question of doubt, whether the common radiating wheel does not admit of a construction, which, in average of weather and circumstances attending a sea voyage, might lead to as little loss of power as the vertical wheel, and at the same time possess the advantage of less liability to derangement.

The first vertically acting wheel which has been employed to any extent in this country is that commonly known as Morgan's wheel. The original patent for this construction was granted to Elijah Galloway, and sold by him to Mr. William Morgan; but it has since that time undergone considerable improvements in its structure and arrangement, and is now extensively adopted by Government in the Admiralty steamers. * * * *

In the year 1837, Messrs. Seawards fitted a vertically acting wheel to the "Levant" steam boat, in which the positions of the paddles are similar to the above, but are brought about by a different arrangement of machinery. This wheel formed the subject of a charge of piracy, on the grounds of being a colourable evasion of the patent of Elijah Galloway. The Vice-Chancellor having given judgment against granting an injunction, the parties tried an action at law, in which they were also unsuccessful; and Messrs. Seawards have now the privilege of making these wheels. * * *

The main difference in the construction of the two is the excentric, which by being fixed at the side of the vessel, instead of in the centre of the wheel, is less adapted to giving motion to the paddles, from acting at one end of them, but has the advantage of allowing the shafts to be continued through the wheel, which certainly adds to its strength.

The author then proceeds to describe a great variety of experiments on Admiralty steamers with various kinds of paddle wheels; the results of which are concisely given in a tabular form. From these he deduces the following useful practical rule to ascertain the power of the wheels.

The diameter to the centre of pressure, or effective diameter of the wheel, being known, we at once deduce the excess of the velocity of the wheel over that of the vessel, or that at whichit recedes in the water to produce the resistance necessary for propelling the vessel. The rule for ascertaining the amount of this resistance or pressure on the vertical paddle, is to multiply the square of this velocity by the area of the paddle board and by $62\frac{1}{2}$ (the weight of a cubic foot of water in lbs.), and divide by $64\frac{1}{3}$; the pressure upon a surface moving in a fluid, being equal to the weight of a column of water whose base is the area of the surface, and altitude that through which a body must fall to acquire the velocity. This number, multiplied by the velocity of the wheel, will express the power expended on the vertical paddles; and this divided by the whole power of the engine, will give the proportion consumed on the vertical paddle, given in column 18.

Next follows a Table, exhibiting the ratio of the velocity of the wheel and vessel, the pressure upon the vertical paddle, and other results calculated from the preceding experiments. It is to the last column of this table, that reference is made both in the preceding, and in the following, extract.

In examining column 18, a striking difference is seen in the proportion of the power of the engine expended on the vertical paddle, in Morgan's wheel and in the common wheels; the mean of the former being ·546, and of the latter ·151 and ·197. The difference arises from the nature of the action: *in the new wheel the vertical position is the most effective in propelling the vessel, and in the common wheels the least so*;—a fact which, although little known among the projectors of paddle wheels, and even among engineers, who are constantly witnessing their daily performance, it is very essential should be understood before any calculation or judgment can be formed of the construction and proportion of wheels best adapted to steam vessels, under the different circumstances and various kinds of duties in which they are employed: we beg therefore to call the attention of the reader particularly to this point.

The author explains the manner in which the power of the engine is expended, both in the common paddle wheel, and in the *new one* (Morgan's) with *vertical paddles*; and draws a comparison between the lost power in the two.

In the action of the common wheel there arise, as we have before described, two kinds of lost power,—one from the retrograding of the wheel, and the other from the oblique action of the paddles; and we are now enabled to estimate the amount of each of them with considerable accuracy, and thus to draw a comparison of the efficiency of the two constructions of wheel in different states of immersion. * * * * * *

When the wheel is slightly immersed, little or no advantage is gained from the vertically acting paddle, the loss from the additional velocity required to obtain the necessary resistance or receding of the wheel, being fully equal to that of oblique action in the common wheel. The only remedy for such an evil is the increase of the number and dimensions of the paddles, both of which are difficult to accomplish in Morgan's wheel: we may therefore very fairly conclude, that in the navigation of rivers or smooth water, where generally little variation is required in the degree of immersion of the vessel, the common wheel, if properly proportioned, is preferable to the vertically acting wheel, in consequence of its admitting of a larger surface of paddle board.

In the case of deep immersion the effect is very different: here the loss from oblique action in the common wheel becomes very serious, so that the total loss of the engine amounts to ·447 of that expended, while the loss from Morgan's wheel remains nearly the same. It therefore appears that the latter has great advantages over the common wheel for sea purposes or long voyages, where the immersion of the vessel is constantly diminishing by the exhaustion of the coals and other stores required at the commencement of the voyage. The loss from the oblique action of the paddles must also be very great in rough weather, from the degree of immersion to which the wheel is subject; in addition to which, the paddles entering the water with so great a velocity, receive a reaction or blow which has the effect of nearly bringing up the engine, and there in consequence results a loss, in addition to that of oblique action, from the power required to put the mass of machinery again in motion. The advantage which the common [illegible] possesses in still water, of presenting a larger surface of paddle board, [illegible] now exist, as a large surface has a tendency to bring up the engine, and throw all the work on the oblique paddle, which is in every case disadvantageous. In fact, the desideratum that has to be aimed at in every wheel, is to throw as much work as possible on the vertical paddles, where there is no loss from oblique action; which can be accomplished in the ordinary construction when the immersion does not exceed one-fourth of the radius, and a large surface of paddle board taken advantage of; but at sea it can only be effected by reducing the number and surface of board, which is at a great sacrifice of speed when the vessel is in still water,—a condition to which the same vessel is of course liable; and hence arise the disadvantages and loss of power of the ordinary wheel for sea purposes.

The next paddle wheel for consideration is the *cycloidal*; to the description of which the author applies himself, after premising the following observation.

The vertical wheel, although possessing in its action the advantages we have pointed out, is however attended with several serious practical objections. To effect the vertical position of the paddles, considerable complication is necessary in the construction, and a great number of moving parts are required, which are not only attended in the commencement with a great outlay, but require continual repairs, and are liable to derangement. * * * * * * *

The principle of this contrivance consists in dividing the paddle into a number of parts, which are placed upon the wheel in the curve of a cycloid, so that they enter the water at the same spot, and follow one another so rapidly as to cause little resistance to the engine on entering the water; and afterwards separate, so as to afford full scope for their action in passing the centre, and in coming out allow the water to escape readily from them. * * * * * * *

In river navigation, where there does not exist the necessity of deeply immersing the wheels, and the common paddles can be made much broader without inconvenience, the advantages of this construction will not be so much felt: at the same time, it may always be employed beneficially, and will occasion less lost power than the common wheel.

The formulæ for ascertaining the relation between the diameter of the wheel, the area of the paddle, and the velocity of the vessel, will be of great service to the steam-ship builder. The advantage to

be obtained from *reefing the paddles*, is pointed out; and the devising of an easy and expeditious mode of effecting this object, is mentioned as a subject deserving attentive consideration.

A ready method of reefing appears at present to be attended with some practical difficulties, from the alterations that are made being required while the vessel is at sea. The advantages which would be derived from it, particularly where speed is of importance, are evidently so great, that I hope still to see it accomplished; but should it ultimately be found impracticable, the best remedy is the use of the vertically acting or cycloidal wheel, and keeping the diameter as large as possible, by increasing the length of the stroke of the engine, so that more or less immersion will make comparatively less difference in the action of the wheel; the larger the vessel the less will be the loss, because the diameter of the wheel increases in a greater ratio than the degree of immersion. In the Victoria, which is fitted with the cycloidal wheels, it is proposed to remove the outer paddles before starting, and to replace them during the voyage when the vessel is sufficiently light, which, if it can be effected, will be attended with considerable advantage; but much less than if a ready method of reefing could be devised, so that the surface of the paddle-board should be at the constant command of the engineer.

Mr. Barlow enters very fully into the consideration of the means of adapting steam vessels to long voyages,—a subject exciting vast attention at the present day; this portion of the paper will consequently be read with much interest. After enumerating different performances of various government steam vessels, the author sums up with the following cheering view of the prospects of Atlantic steam navigation.

The results of these voyages are indeed so favourable, as to set the question at rest as to the practicability of the American voyage; the consumption of fuel has been so reduced by the superior construction and manner of working the engines, that these vessels, although comparatively small, are enabled to perform a voyage much exceeding that to New York; and consequently the American Steam Company's vessels, whose capabilities for distance are greater in the ratio of 7 to 9, from the superior tonnage and power, must perform the voyage, under any circumstances, with the greatest facility.

The following observations are given under the head of *Iron steam boats*, the general adoption of which Mr. Barlow looks to as probable.

It is necessary to mention, among the improvements which are likely to add to the capabilities of steam vessels for making long voyages, the introduction of iron as the material of construction, the use of which has been attended with complete success in every instance in which it has been tried. The advantages of iron vessels are stated to be, that they do not weigh one-half that of a timber sea-going vessel, and they therefore draw considerably less water, and give a greater speed with equal power; greater safety, in consequence of being divided into water tight compartments by iron bulkheads; and greater economy, as they do not require so many repairs. The capacity is also increased for passengers and goods: a wooden vessel of 30 feet beam is only 27 feet 6 inches inside, while an iron vessel would be 29 feet 6 inches; consequently a saving of two feet is produced throughout the whole length of the vessels.

To the advantages enumerated, we would add what we consider a very important one arising from the use of iron as the material of construction,—that it will obviate the dreadful and hazardous effects of fire, to which steam vessels as at present constructed are fearfully liable.

No. IV. is a Time and Traverse Table, by Captain Robert Oliver, R.N.; calculated to show the advantage of rigging steam vessels for long voyages on the principle of spreading the greatest quantity of canvass, with the least possible resistance from masts and yards when steaming.

No. V. (and as far as the work proceeds in the present part, the last,) consists of a Memoir of her Majesty's Steam Ship the Medea, during a service of nearly four years, by Thomas Baldock, Lieut. R.N., K.T.S. It contains a great deal of valuable information on the subject of the adaptation of steam vessels to long sea voyages, and their applicability to purposes of war,—information the more important from the circumstance of the "Medea" having undergone a fair trial in her four years hard and constant service in the Mediterranean.

This ship was launched at Woolwich in September, 1833, and immediately fitted with two engines of 110 horse power each, by Messrs. Maudslay and Field, who had supplied those to the other four war steamers, and who had succeeded by their adaption of boilers, &c. in producing the best possible effects with the least proportion of fuel then known; the wheels being according to the plan of Mr. Morgan, with the revolving vertically acting paddle, of which a full description is given in another part of this work.

The masts, sails, and rigging, as well as the internal fittings, were principally proportioned by the constructor, assisted by such modifications as the skill and experience of Captain Austen, and Mr. Peacock, the able master of the vessel, suggested. It will not be uninteresting to our nautical readers to state, that the Medea has three masts,—the foremast being rigged nearly as that of a brigantine; the mainmast and mizenmast having each a lower gaff-sail and gaff-topsail; the arrangement of the standing and running rigging being so adapted, that the upper masts, yards, &c., may be lowered to the deck with the greatest facility, and again reinstated with little labour,—thus affording the least possible resistance when steaming head to wind, and yet spreading a large quantity of canvass, when under sail, and all the gear in its place.

The armament consists of two guns of great calibre, capable of carrying heavy shot further than the range of the largest guns in use in sailing ships of war, and also calculated to throw shells: besides these heavy pieces of ordnance, which are mounted on pivots, one before the foremast, and the other abaft the mizenmast, she has less guns of considerable weight, intended to be "transported" about the deck as occasion may require, with a full proportion of small arms for a crew of 120 men, for the purpose of repelling boarders, should unforeseen and improbable circumstances place her in close contact with a heavy vessel of war,—the obvious tactics of a war steamer being to keep out of range of an enemy's guns, which she may always do by maintaining a position in the wind's eye of an opponent, and assailing her adversary with very little chance of receiving any damage in return,—a good steamer having no difficulty in keeping to windward of the best sailing ships, even in strong winds: and it is quite evident that in a calm the steam vessel may take any position she pleases.

During the period of her accompanying the fleet under Sir Josias Rowley, which she joined at Vourla Bay in the autumn of 1834, the "Medea" exhibited her powers of sailing independent of steam;—proving indisputably, that steam ships can be so built as to sail equally well with any other vessels. In his Memoir, the author has given several particulars of her sailing, which go to prove this point; we select the following instance.

The first trial of sailing after the Medea joined the squadron was on the 3rd of November, in company with Her Majesty's ships Scout, Childers, and Columbine. These vessels being ordered on some detached service, it was considered a good opportunity, as the wind blew directly into the Bay of Smyrna, for the steamer to test her qualities of "beating" to windward with such fast sailing ships; and we accordingly find that, although labouring under all the disadvantages of a first experiment, which the seaman will not fully appreciate, she was, with wheels revolving loosely in the water, nearly equal to both the first-named vessels, and only beaten in any very decided degree by the Columbine, built by Sir William Symonds, the present Surveyor of the Navy. Having gained the outside of the bay, the ships proceeded towards their destination, and the Medea remained for some hours exercising the crew, in performing the evolution of "tacking," and in developing such modifications as might be applicable in the performance of her duties as a sailing ship of war, of which she had hitherto had no practice. It was ascertained that, with the moderate breeze then blowing, she made nearly a straight course at five points from the wind, and meeting with two Greek polaccas, well known to be fast vessels, she joined company, beat them both "on a wind," and returned to the anchorage at Vourla.

The Lieutenant further points out important advantages as likely to result from the co-operation of steam vessels with ships of war: but as we have already exceeded our limits in extracting from the various papers contained in the work before us, we are precluded from giving several very interesting passages to be found in the memoir of the "Medea;" and must content ourselves with confidently recommending it to the attentive perusal of our readers.

We feel it also incumbent upon us to state, that the numerous engravings accompanying both this memoir and the other papers in the Appendix, will be found deserving of the attentive consideration of the professional reader. We look forward anxiously to the appearance of the second part of the work, and shall recur to the subject when we have the whole before us. If the second part prove equal to the first, the present Edition will be a work of national importance, and of standard value for reference by the profession.

A Treatise on Engineering Field-work: containing practical Land-surveying for Railways, &c., with the theory, principles, and practice of Levelling, and their application to the purposes of Civil Engineering. By Peter Bruff, Surveyor, &c. London: Simpkin and Marshall, 1838.

Mr. Bruff's work begins with directions to be observed on commencing a survey,—method of taking offsets,—of surveying single enclosures,—of taking inaccessible distances with the chain, as the width of a river, &c. Most of these observations are to be found in all similar works; but of course, in an elementary book intended for students, they are necessary for obtaining a correct knowledge of land-surveying.

There follows an *Example in Railway Surveying*, illustrated by a plan showing the method of surveying and laying down the base line, and surveying the property on each side. This will be found useful by the student.

The following article, on *Parish Surveying*, is too brief; consider-

ing the vast importance of this description of surveying at the present time. The principal part of the matter, has been selected from Captain Dawson's directions for the Tithe Commutation Survey. The following passage which we select, contains some useful hints:—

The extracts we have made from Captain Dawson's Report are so much to the point, as necessarily greatly to abridge our remarks, which will be confined simply to the guiding and directing persons in the measurement of such lines as are therein recommended. In the first place, then, we will endeavour to point out the best and most correct method, of measuring the principal base through the entire length of the parish. Previously to commencing or arranging the work, the surveyor should, if possible, procure an old map of the parish, which, however incorrect it may be, will still serve generally to point out the best parts of the parish through which to pass his lines; but whether this is obtained or not, let him be in no hurry to lay out the work, but look carefully to the consequences resulting from transverse lines running through various parts of the parish—whether their extremities can be easily connected, and if they intersect any particular or important points within, or are on, with any without the parish. This is particularly to be attended to, as it would greatly facilitate the tracing of the boundary at any future time.

We will suppose, then, the surveyor to have decided on the point of commencement and direction of the base, which, if possible, should be on, with some conspicuous permanent mark, without the bounds of the parish, as a church, windmill, house, or such like. At this point set up your theodolite, and ascertain very exactly the angle formed by this line with the magnetic meridian; then take angles to several conspicuous objects around, which would serve hereafter very accurately to determine the point. At this spot erect a pole, very perpendicular, and commence the measurement of the line; but before proceeding further, it cannot be too strongly enforced on the surveyor's mind the absolute necessity of extreme exactness in this part of the operation; for which purpose a much longer chain is recommended than that usually adopted.

At about every five or ten chains, it would be advisable to drive a stake firmly into the ground, with the chainage inscribed thereon in Roman characters: thus, if at every ten chains, call the first ten 1, at twenty it would be 2; or if left at every five chains, at five it would be 1, at ten it would be 2, and so on. The reason of this will be presently apparent.

The roads, rivers, brooks, fences, &c., as they are crossed, should be very carefully noted; but in this stage of the proceedings it would be quite useless putting down false stations at nearly all the fences, as in common surveying. Offsets, if within distance, should be taken to all conspicuous objects. At certain prominent points, as you pass along, set up poles; these will serve to keep you in a direct line, even if you entirely lose your forward object. Your forward chainman must at each chain's length plumb back to those poles you have erected, and by keeping them exactly in a line, you need not fear of departing from your true course.

If you come upon a house, or gentleman's pleasure ground, through which it is impossible to measure a line (but this always should be avoided, if possible:) the means of overcoming the difficulty will be found by referring to a chapter on the subject, in the section devoted to levelling; but the most ready and correct method would be, very carefully to measure an angle with the theodolite, either to the right or left of your line, of exactly 60 degrees, and measure out any length until clear of the obstruction; then take another angle of exactly 60 degrees, and measure the same distance as the last line. This will bring you to the exact spot you would have arrived at, could you have continued your line on without interruption. You will thus have measured two sides and angles of an equilateral triangle. The remaining angle and side will be the same; that is, the angle will be 60 degrees, and the distance, if it could be measured through the obstruction, would be exactly the same as that of either of the measured sides; or a line forming any angle with the base (but which must be determined) being measured clear of the obstruction, and an angle taken at the extremity so as to cut the base beyond the obstruction, the length of this side and of that passing through the obstruction may be easily calculated by plane trigonometry. This difficulty overcome, and the continuous distance entered into your book, we will proceed onward; but the poles you have set up behind are not visible, neither probably is your forward mark. To extricate yourself from this dilemma, measure the supplementary angle of 120 degrees from the last measured side of the equilateral triangle; this will direct you in the precise line; but to verify it, ascertain its bearing, which would be the same as at first: and in this manner you will be able to overcome all similar obstructions.

We will now suppose the surveyor arrived at the extremity of his base, where he must set up his theodolite, and take the angle of one of the side lines, which should not be very oblique, but as near 45 degrees as circumstances will admit, and, as directed for the base, should, if possible, be in a line with some natural mark. To measure this angle which is most important, with the requisite degree of accuracy, it should be repeated several times, and a mean taken as the correct angle. Set up a pole at the extremity of the base, and measure this line in a similar manner as directed for the base, putting down stakes at intervals. When arrived at the boundary of the parish, or so far as may be desirable, set up the theodolite and measure an angle from the last line to some object on the opposite side of the parish, transversely, to your base, and another angle to the first station at the commencement of the base line: set up a pole at the exact spot from whence the angles were taken, and measure the transverse line, which can be measured in a perfectly straight line, by adopting the same means as already directed. When this line is measured up to the crossing of the principal base, stop, and from one of the stakes previously left, measure up to the exact spot at which you cross, and enter the two distances in the field-book. Continue the measurement of the transverse base (driving in stakes at regular intervals as before), to the extremity of the parish, or so far beyond it, as by tye-lines, measured to the extremities of the principal base, the entire parish can be circumscribed; or leaving out such small portions only, as may be determined by small triangles from these principal lines.

In throwing out triangles to enclose any part of the parish that may be without these side lines, if an instrument be used, there will be no occasion to extend them back to the base, without the figure should be very large, or the internal lines can be used for other purposes, than merely to verify the position of the figure; but where a chain only is used, it is indispensable to the correct fixing of the figure that those lines should be so extended to one of the bases. From the extremity of the transverse base, very accurately observe the angles of the tye-lines to the extremities of the principal base, and measure these tye-lines in the same accurate manner as the bases, leaving stakes at intervals, and taking offsets to the parish boundary and conspicuous objects wherever within distance. When these angles and tye-lines are measured and protracted, there will be four principal stations in the parish very accurately determined; and by these stations being correctly fixed, each stake on the lines connecting the stations, may be considered as a correctly determined station, and used as such.

It would be advisable, before filling in any portion of the work, to get the boundary of the parish, and all the work laying outside the lines; but if not all the boundary, at least the part on that side from whence it is intended to commence filling in. Internal lines may now be used wherever it is thought necessary, the surveyor confining himself to one portion of the survey only, and entirely filling it up before any other part is commenced; his work will then never get confused. With regard to the direction of such lines as it may be necessary to measure within the principal ones, circumstances must alone direct; but lines may be measured in any direction within this boundary, without regard to poles or false stations that may have been erected during the measurement of the base or tye-lines; for, having stakes at regular intervals of five or ten chains, the distance from any one of them to the point at which an internal line crosses can be measured, and the point determined as correctly as if that spot had been fixed on for a station, when measuring these principal lines; and thus can lines be measured in any direction, always observing that from one point to another must be perfectly straight. The angles of the first few internal lines should be very carefully taken, which will fix their position without regard to their measurements; and on the scale being applied thereto, the distance at which any one of them bisects either of the principal lines will be the same as measured in the field, and the point bisected will be at the same chainage as determined by reference to one of the stakes. If on protraction of the angle it should not pass exactly through the point as determined by measurement, it should be made to do so; more dependence having to be placed on the distances than the angle in this case; but by taking the angle, any error committed in putting down or measuring from any one of the stakes will be immediately detected: points thus determined must be correct.

If the surveyor is expert in the use of the sextant, it would be very desirable to have the angles taken of all the lines, except where well tied; but where only determined by their extremities, the angle should in every case be taken. Particular care is necessary in reducing lines measured over steep ground, to the horizontal plane; for the method of doing which, see description and use of theodolite, also the method of correction with the chain only. The surveyor is advised to lay down his work as he proceeds, if done every day it would be best; he will then, in the event of committing an error be able immediately to rectify it. The sextant may be used with advantage in filling in, but on no account should any other instrument than the sextant and theodolite be employed.

With regard to computing the aggregate quantity of land in the parish, the principal measured lines, as suggested by Captain Dawson, may be used for that purpose, equalizing and arranging into triangles what may be without; and for the separate enclosures within, they may be equalized and arranged in a similar manner. But it would appear to us the most correct method to form parallelograms, or squares, as usually done in large surveys, of about two chains, by which the quantities in each enclosure would be very correctly ascertained; and for the aggregate, every fifth or tenth parallelogram might be distinguished by a thicker line; the aggregate could then be easily calculated, there being so many parallelograms of ten or twenty chains square, or as much larger as pleased; the broken parts of the parallelograms would be calculated as directed in another part of this volume. By this method the contents of all the enclosures added together, and the computed whole would be found (if carefully done) to be so nearly the same, that the difference would be beneath notice. The contents of the whole, computed by the measured lines, might be used as a check on the proceding method. The lines forming the parallelograms should be permanent, either in faint red or blue; but probably blue would be the best, so as to be distinguished from the measured lines, which Captain Dawson desires to have retained. All the entire squares must be numbered consecutively, and the broken figures (as where a fence crosses), calculated separately; and it will be evident that, in this separate calculation, the ascertained contents must be correct; for, having the contents of the whole square, its parts added together must of course be the same.

The next subject treated of, is *Subterranean Surveying;* under which head Mr. Bruff gives some useful directions; but is, as under the previous one, far too brief. He has here fallen into an error, against which we must guard our readers, respecting the variation of

the needle, which he states to be at the present time about twenty-seven degrees Westward of North;—whereas the truth is nearer twenty-three and a half. If Mr. Bruff found this variation by the method which he immediately after describes as adopted by practical miners, it is no wonder he has made such a mistake; he says:—

The method adopted by practical miners for ascertaining the variation (for it is not the same in all places), is, to erect a pole exactly perpendicular—its shadow at twelve o'clock will be due North and South, or in the direction of the true meridian; besides the above variation of the needle from the true meridian it has a diurnal variation, which has been often observed to amount to one degree and a half, which may account for inaccuracies that have occurred where the greatest care has been observed in the use of the instrument.

Now it happens that the shadow of the pole can only be *approximately* North and South on four days of the year, and it varies more or less from the meridian at all intermediate times;—we say, *approximately*, because the equation of time, which is the cause of this phenomenon, is not at its minimum (or nothing) precisely at twelve o'clock in long periods of years.

Next follow, methods of protracting and plotting surveys,—reducing figures and equalizing boundaries,—and computing areas.

The next division of the work, consists of a description of the uses and adjustments of the various *Instruments employed in Surveying;* the principal portion of which has been extracted from Mr. Simms's "Treatise on the principal Mathematical Instruments employed in Surveying, Levelling, and Astronomy."

The portion of the treatise which relates to *Levelling*, is by far the best and newest, containing several useful directions and much interesting information. We shall defer making any extracts from this portion of the work, or further remarks upon it, until our next number.

For the present, we conclude with one remark;—although the directions contained in that portion of the work which we have already noticed, are too brief, and generally to be found in most of the other works on Land Surveying, we still consider that Mr. Bruff's work is an improvement on what has been heretofore published.

The History and Antiquities of the Manor-house at South Wraxhall, and the Church of St. Peter, at Biddestone, Wiltshire. Illustrated by Twenty-two Plates of Plans, Elevations, Sections, Parts at Large, and Perspective Views. Forming Part III. of "Examples of Gothic Architecture," Third Series. By Thomas Larkins Walker, Architect. 4to. London: 1838.

Our Journal is not yet so voluminous as to render it necessary for us to inform our readers, that we gave some account of the Second Part of these "Examples" in one of our earliest numbers. What we there said in the way of general commendation, is equally applicable here; the same fulness and perspicuity of delineation—the same scrupulous fidelity to the minutest circumstances, being manifested in this third, and, we fear, concluding portion of Mr. Walker's work. In regard to the meritorious qualities above named, we are acquainted with no other that can come into competition with it; for even those which confine themselves to the illustration of a single building, are almost all, more or less, unsatisfactory;—invariably leaving much to conjecture that required to be elucidated beyond the possibility of misconception. We could point out some remarkable, and not a little curious instances, in proof; and that, too, in works which at first sight appear to contain the most complete information that can be required; nevertheless, when we come to consult them for purposes of study, they leave us utterly at a loss as to a variety of particulars, and in all probability precisely those respecting which we are in search of information. Neither is this very important defect confined to works of an inferior grade, but extends to others both carefully and tastefully executed, as far as mere drawing goes; yet better calculated to please the eye than to furnish lessons of real instruction.

The case is widely different with Mr. Walker's publications: he knows what the professional student requires, and how essential it is, in order to acquire a thorough and accurate notion of any building, that its parts should be shown not only minutely, but completely, so that every circumstance of form be clearly expressed. Unless this be done, the most carefully drawn representations give us only generalities, and are therefore apt to beget a habit of hasty, superficial examination, because they supply materials for nothing further, except what relates to composition. They are even apt to mislead, by suppressing, if not entirely—in a great degree, those particulars of detail upon which the expression of style so much depends. It is to the want of due attention to, and study of, such apparently trifling minutiæ, that we must partly ascribe the poverty and crudeness observable in so many of our modern Gothic buildings and designs, where the expression of detail is quite overlooked, and consequently that of finish also. Were we to say that such things bear no resemblance whatever to the style they profess, it would perhaps be paying them a compliment they do not merit; because, in truth, resemblance enough there is, to make us feel how still greater is the disparity, and how offensive it is. Strange as it may perhaps sound, we are, moreover, persuaded, that to the superficial study of detail is in great measure to be ascribed the want of original ideas; because he who does not thoroughly understand its principles, in the style which he adopts, and the modifications it admits, must of sheer necessity adhere to copying, and feel himself utterly at a loss to give any individual expression to his design, without incurring the danger of departing entirely from the style itself. He is in the situation of a painter who, with no more knowledge of the human figure than what will enable him to people a landscape decently, should undertake an historical piece; which would be like Martin's or Turner's attempting to paint a cartoon.

Considered as documents of style, the subjects here given are more valuable than they may appear to be on first inspection, for neither the house at South Wraxhall nor the church at Biddestone strikes by any great architectural display or richness of character; yet will they be found to contain many valuable elements, of a kind likely to be overlooked where the attention is engaged by what are more obvious merits. The Manor-house is an assemblage of various parts erected at different times, from the reign of Henry VII. to that of James I. inclusive. The hall and porch belong to the first-mentioned period, of which they exhibit interesting and characteristic specimens, not at all the less valuable from their being upon a moderate scale, and having little of positive decoration. The latter of these, deserves to be particularly studied for its sober beauty, and the excellent taste it displays. It is marked by a charming simplicity, resulting not from nakedness or poverty, not from the omission of details, but from those details being treated with gusto, and perfectly imbued with style. This remark applies to the adjoining portion of the building, forming the exterior of the banquetting-hall. The features are exceedingly few, and by no means of a showy sort; there is hardly anything whatever of what modern imitators have recourse to in their designs—not even so much as either string-course or embattled parapet, that *sine qua non* of *their* Gothic; nevertheless the whole is replete with expression, both architectural and picturesque. Its superior quality will be best appreciated by comparing it—we will not say with the generality, but with some of the best modern instances of the style, as applied to domestic architecture; which will, when so tested, be found for the most part flavourless and mawkish. It must, indeed, be confessed, that what we here behold offers no model suitable for direct copying: on the contrary, it will exercise all an architect's taste and ability to produce what shall be equivalent in character, although necessarily greatly modified from the express species here presented to him. This Manor-house, however, sets before us not only much that is truly excellent, but some things also that ought to be avoided: among the latter we unhesitatingly place the interior of the drawing-room, whose outré style of decoration affords a fair sample of that vitiated taste which prevailed in the times of Elizabeth and James;—capricious, yet wearisomely monotonous; costly, yet without richness; finical, yet devoid of delicacy; full of puerile conceits, at once fantastical and frigid; abounding in the most harsh and disagreeable contrasts; and, in short, displaying the most coarse and vulgar taste. Even did we not already know, from what he has said, that Mr. Walker himself will agree in the opinion we have just expressed, we could not prevail upon ourselves to speak otherwise. Still, we do not object to the view of that apartment being given, because we feel that it will justify both him and us, and convince more forcibly than words can do that the style is radically and incurably vicious.

The Churches of London. Nos. XV. XVI. and XVII. By George Godwin, Jun. F.S.A., assisted by John Britton, Esq., F.S.A. London, C. Tilt. 1838.

We have twice before noticed this very interesting and popular work, and have much pleasure in renewing our former expression of satisfaction in it. The views are very judiciously chosen, so as to exhibit well the general effect of the architectural character of the various churches; and the accompanying history and critical notices are particularly interesting. To show the general character of the work, we select the following passage from the history and description of "St. Vedast's, alias Foster, Foster Lane," in the sixteenth number, which begins the second volume.

The interior of the church is divided into a nave and one aisle by a range of Tuscan columns, connected by plain arches, on the south side of the building. The ceiling, slightly coved next the walls, is formed into one large panel, which encloses others of smaller dimensions, by bold and rich

wreaths of flowers and fruits; and the smaller panels contain foliage in a style now much too generally used, namely, the debased Italian, which especially prevailed in France during the reign of Louis XV. but is known as the style of *Louis quatorze* his predecessor.

The altar-piece may be called magnificent of its class; it consists of four Corinthian columns, carved in oak with entablature and pediment of the same material, surmounted by urns, and profusely decorated with cherubim, palm-branches, and other ornaments. In the centre above the entablature is a well arranged group of winged figures, carved in very bold relief around a circular panel; and beneath it is a sculptured representation of a pelican. The figure of this bird occurs in the altar-piece of several of the metropolitan churches: and we will venture to suppose,—in the absence of information touching its introduction—that it was used to typify the Saviour. Until a few years since, it was generally believed, and indeed the opinion is even now current with the vulgar, that the pelican is accustomed to feed her young with her own blood, if unable to procure other food; and so long as men believed this to be the case, the resemblance that this bird afforded to Him who shed his blood for us must have been striking.

Two windows at the east end of the church, (one on each side of the altar-piece, over which is a third,) are covered by transparent blinds painted to represent the delivery of Peter from prison, and the Transfiguration; and we will take the occasion to remark, that the very available means of assisting to give character to our sacred edifices, which painted blinds present, might, we think, be employed with advantage more often than it is, in the absence of funds for the attainment of stained glass.

The general appearance of the interior of the church is much injured by the want of symmetry and regularity caused by the intrusion of the tower, (which stands on the south side of the building at the west end,) and by the introduction of a single aisle. In addition to which, the sides of the edifice do not form right angles one with another, owing probably, to the circumstance, that the architect when rebuilding the church, used all the old walls that were available.

The exterior of the church is represented by the annexed engraving, and is worthy of remark and admiration on account of the original and graceful spire by which the square tower at the south-west corner of the building is surmounted. It is divided into three stories, the lowest presenting four concave faces with clustered pilasters upon piers at the angles. The centre one has four convex surfaces with plainer piers at the angles, and the third consists of an obelisk, or short spire crowning the whole. The parts are simple and harmonious.

In the history of St. Giles', Cripplegate, we are informed that the remains of the immortal author of "Paradise Lost," rest within the walls of this church.

He was buried here under the clerk's desk in 1674; but for many years there was no memorial of him within the church. Through the liberality, however, of the late Samuel Whitbread, Esq. a fine bust of the poet, by Bacon, has been set up against one of the columns on the north side of the nave, with a tablet beneath, (terminated by a flaming sword, the serpent, and the apple, pleasingly grouped,) which bears this inscription:—

JOHN MILTON,
AUTHOR OF PARADISE LOST,
BORN DEC. 1608, DIED NOV. 1674.
HIS FATHER, JOHN MILTON,
DIED, MARCH 1646.
They were both interred in this Church.
SAMUEL WHITBREAD, POSUIT, 1793.

The Monthly Chronicle, No. 3. *Architecture of London.*

THE commencement of this article, which sets out by asserting that literature "might seem to repudiate a union with science and the fine arts"—rather singular doctrine by-the-by—is too obscure and mystified to be at all to our taste. All that we gather from it is, that it is intended, by way of apology, for introducing the subject of architecture "among papers of a purely literary character;" though the apology might very well have been spared, seeing that such topics as "Weather Almanacs," and "Coal Trade Combinations," had been previously discussed; none of which, according to our poor apprehension, can exactly be considered as "purely literary." However we are thankful that this preliminary is as brief as it is obscure, for in the course of a few paragraphs, the writer reaches his subject; yet not till after he has paraded before us the lines of pack-horses, hand-litters, and horse-litters, to be seen in the streets of London of olden times, and now superseded by vans, omnibuses, cabs, and carriages of different kinds, both describable and indescribable. This might perhaps, have very well been spared, for the reason that it occupies space which the writer would have turned to better account by expanding some of the remarks on buildings, which he afterwards dismisses too hurriedly; so that while he proves somewhat lengthily diffuse where he might have been silent, he is provokingly laconic, where his criticism might have been instructive. But the same will probably be said of ourselves; let us therefore proceed at once to give some of his opinions:—

The rapid progress of good taste, may be estimated even by a comparison between Regent-street, and King William-street in the City. Very beautiful in design are many of the individual buildings of the former, and the effect as a whole is striking; but in the latter, a greater unity and simplicity are combined with more real grandeur and fitness, as adapted to their intended purpose. A comparison of Portland-place with Pall-mall, the modern street of palaces, presents a more striking contrast. One great cause of the irregularity of appearance in our streets, has always been the discordant character of the shop-fronts; but these are daily becoming more ornamental, and with a little regulation, easily enforced, their projecting cornices might be made to produce a very beautiful effect.

With the general tenour of what is said in the above quotation, we agree, particularly in regard to the vast superiority of Pall-mall over Portland-place; which latter, considered as architecture, is no better than its water-gruel, not nauseating, indeed, but most insipid. For our part, however, we have yet to learn what are the individual buildings in Regent-street here spoken of as being very beautiful in design. Some of the façades are comparatively good, when judged of by what we observe in their neighbours—many of which are vile enough in point of design—yet among all of them there is not one that will bear the test of leisurely examination. Here and there we meet with some pretty parts, and with something like good composition; nothing farther. All have the appearance of having been erected from hasty unrevised sketches. There is in them a good deal of tawdriness and show, and very little richness; a great deal of poverty and meanness, without any approach to simplicity;—Corinthian fluted pilasters stuck up against "hole-in-the-wall" houses, and other vices of that kind; besides the defect of insuperable littleness arising from the number and smallness of the windows, occasioned in their turn by the want of space within the individual houses,—a defect not at all remedied by the gratuitous introduction of pilasters, which leave no room for dressings to the windows between them. King William-street, in the City, may perhaps be a degree better, but must certainly yield the palm for propriety and consistency of architecture to Moorgate-street, leading from Prince's Street to Finsbury Circus.

Again, we are rather sceptical as to that improvement in shop-fronts, which the writer seems to be of opinion is now taking place. They may, indeed, be more ornamental or ornamented; yet so far from being more architectural, some of the lately erected ones we have noticed are not at all better than their predecessors; for the whole front of the shop is little more than one surface of plate-glass, the actual support of the wall above being within, so that the upper part of the house appears not to rest upon, but to be suspended over, the lower. Why it should be judged indispensable to give the whole extent of frontage to shop windows, it is not easy to say. Most assuredly, the practice is not intended to verify the adage, that "good wine needs no bush;" neither does it seem quite in accordance with what may be considered shopkeeping policy, because where so much show is made at the windows, persons are often spared the necessity of inquiring what articles there may be within. Doubtless every shopkeeper is anxious to make as great a display as he can, and not to be outdone in that respect by his neighbours; yet were all the shops in the same street built architecturally on the same plan, no tradesman could complain, because his shop would at least make as much figure as any of the others. Of course, where the practice complained of is established, it will not be abandoned; but whenever new streets of shops are formed, or extensive alterations occur in old ones, it might be guarded against, just in the same manner that in Regent-street, the new portions of the Strand, &c., persons are prohibited from covering all the upper parts of the fronts of their houses with their names and trades in Brobdignagian letters; in which way the rivalry of tradesmen was at one time carried to a most preposterous extent.

The writer proceeds to animadvert upon the new churches, which he reproaches both with the meanness of their materials and the poverty of their designs. It must be acknowledged, that in such buildings, architects have been greatly cramped by the inadequacy of the funds placed at their disposal; still there is no excuse for the poverty of conception evinced in most of the designs themselves, since the necessity for economizing ought rather to stimulate their invention, and lead them to devise such architectural character and effect as may be attainable without the expensive yet common-place decoration they almost invariably adopt. Only one attempt of the kind as yet, as far as we are aware, has been made, namely, Mr. Pennethorne's new church in Gray's Inn-road; which although not quite so satisfactory as it might have been rendered by a little more study, deserves to be mentioned, were it only as being greatly preferable to the common-place schoolboy *Greek* portico, stuck up against what might else pass for a Quaker's meeting-house. In fact, the latter is of the two by far the less exceptionable, inasmuch as it

is better to exhibit no taste at all than bad taste, and to make no pretensions than to make them only to give evidence of failure.

The writer next passes on to the New Houses of Parliament, and Mr. Barry's design for them, into which he enters at some length; but we shall merely remark, that he is decidedly favourable to it, and also to the site. After this he continues:—"That we *have* failed, failed lamentably, is undeniable," in proof of which he cites the City of London School, "the main front of which," he says, "is the screen of the grand entrance to a baronial hall, caricatured after the fashion of a scene in an Easter-piece, or the opening to a pantomime;"—severe, yet not very unjust censure. In fact, all the detail is excessively poor and insipid, while there is much in the general composition extremely faulty. The National Gallery does not fare at all better, being characterized as "at once the greatest and most obtrusive blunder of the day." That it has many defects, we admit; still we think that its architect has been somewhat too harshly treated, and that sufficient allowance has not been made for the difficulties he had to contend with; and it is questionable whether any of those who have been most violent in their outcries against that edifice would have done at all better themselves, had they been in Mr. Wilkes's situation. That they would have committed precisely the same faults, we do not say; but they would very probably have committed others quite as numerous, and equally great, if not greater.

If we do not agree with the writer in his unqualified reprobation of that building, as little do we accord with him in the praise he is pleased to bestow on Vulliamy's new front to the Royal Institution, in Albemarle-street, which is not only most common-place in idea, but inconsistent in style. As far as the columns go, it may pass for Corinthian, yet the windows, which have the appearance of having been forgotten, and then afterwards squeezed in between them, do not in the very slightest degree partake of the character of the order. In fact, the writer might with equal justice have applied to that building what he has said of the City of London School, it being the classical style "caricatured, after the fashion of a scene in an Easter-piece, or the opening to a pantomime." Before it was doctored by Vulliamy, the front of the Royal Institution was plain, inoffensive, sober-looking, without anything to excite emotion of any kind; but now, though it may pass as fine with the vulgar, it is calculated to excite only disgust or ridicule in those who can judge of architecture besides by book and by rote.

Topographical Survey of the Borough of St. Marylebone, as incorporated and defined by Act of Parliament, 1832. Engraved by B. R. DAVIES, from Surveys and Drawings by F. A. BARTLETT, under the direction of JOHN BRITTON, F. S. A., &c. London, 1834.

THIS is decidedly one of the best published maps of the day. It contains the important parishes of St. Marylebone, St. Pancras, and Paddington: it also shows the extent and limits of the principal landed estates within the borough. It is further enriched with elevations and plans of the principal buildings. We have very carefully examined the map; and from our personal knowledge of the borough, we can recommend it for its accuracy and undoubted utility, to all residents or possessors of property within its limits.

Map of the maritime County of Mayo, Ireland; by WILLIAM BALD, F.R.S.E.

This map is engraved in the first style of the art, on twenty-five plates of copper; it is on a scale of two inches to a mile. The county is in its greatest length seventy-five English miles, and in breadth sixty-four, containing an area of nearly 2000 square miles. Along the foot of the map, extends a section exhibiting the geological structure of the country; and its physical aspect is graphically shown in a series of profiles along the top. The bogs have been levelled and bored; and the harbours on the coast, sounded. The rise and fall of the ground are delineated in detail, and exhibit many instances of remarkable configuration which will be highly interesting to the geologist, as indicating the past revolutions which have disturbed the earth's surface. The survey was conducted by Mr. Bald, the Engineer; and we understand that the surveying and drawing occupied seven years, and the engraving, ten. The result of all this care and labour, is the very splendid map before us: we hear that copies of it have been presented to the Geological Society, and the Institution of Civil Engineers.

We have been favoured with the following particulars of the survey, which we subjoin in the hope of their proving interesting to our readers. The survey was executed trigonometrically: seven base lines were measured, one of them over a frozen lake more than two miles in length. The chain used was made by Mr. Troughton, upon the same model as that constructed for Mr. Heslam for the American survey. The other instruments were, one theodolite seven inches diameter; and two others, five and four inches respectively: two sextants ten inches radius, divided to ten seconds, by Troughton; and another four inches radius, divided to thirty seconds, by Thomas Jones of Charing Cross, pupil of the late Mr. Ramsden. The account of the measurement of the base lines, and triangulation, has been published in the Transactions of the Royal Irish Academy, vol. 14, part I.; with a table of the heights of the hills and mountains, determined trigonometrically and also barometrically.

The Practical Mathematician's Pocket Guide. By ROBERT WALLACE. W. R. M'Phun. Glasgow: 1838.

THAT this little Work appears now in a second edition, says perhaps more in its favour than a laboured encomium from us. We are, however, obliged to confess that we are surprised at the quantity of matter it contains: tables of logarithms to six places of decimals, from 1 to 10,000; of logarithmic sines and cosines, tangents and cotangents, for every degree and minute in the circle; with rules to find secants, cosecants, &c., and the corresponding natural numbers to them all: tables of decimal equivalents; squares and cubes, and square and cube roots up to 100, &c. &c., all in a small pocket volume of 150 pages. Very legibly printed too, and accurately, as far as we may judge from comparing it in a few instances with our copy of Hutton's tables. For a portable and cheap set of tables, we certainly have not seen its equal; its use, however, of course involves more labour in calculation than the larger and more complete collections.

LITERARY NOTICES.

The History and Description, with Graphic Illustrations, of Toddington, the seat of Charles Hanbury Tracy, Esq., by JOHN BRITTON, F.S.A. This work is to contain 25 engravings; and will be shortly published.

Preparing for publication; A Series of Lithographic Sketches on the London and Birmingham Railway, by JOHN C. BOURNE: with Topographical and Descriptive accounts of the origin, progress, and general execution of this great national work, by JOHN BRITTON, F.S.A. It is proposed that this work, which will illustrate the most interesting objects and features on the Line of Railway between London and Birmingham, shall correspond in size and style of execution with the splendid publications of Roberts, Lewis, Harding, and Stanfield. This size (imperial folio) and style will enable the artist to represent many of the Architectural and Engineering features of the works in a manner calculated to give correct information to the man of science, as well as to the topographer and the amateur.

ORIGINAL PAPERS AND COMMUNICATIONS.

RALPH REDIVIVUS—No. 6.

GOLDSMITHS' HALL.

BY this time, my readers will doubtless have found out or fancied that I am not a little fastidious, very difficult to please, and fond of not only pointing out, but descanting upon defects which other critics have forborne even to hint at. I say, "forborne to hint at," because, to imagine that they could not detect them, would be an imputation upon their judgment; whereas, to abstain from censure where it is merited, reflects discredit only upon their honesty. Of good-natured criticism we have had enough and to spare. To art it operates as a slow poison—agreeable to the palate, and destructive to the constitution. However, the question which mainly concerns my readers, is, not whether my observations be good-natured or the reverse, but whether they are sound in argument and correct in doctrine. If it can be shown that they are not, let them be refuted by those who are capable of instructing the public better.

This must of course, it will be said, be intended as a prelude to something more than usually severe. I am going to cut up Goldsmiths' Hall without the least mercy. It will then, be an agreeable surprise and relief to my readers, when I inform them that I intend doing no such thing. There is much in it that is good; much also, that might have been much better. Compared with the old building, it is as "Hyperion to a Satyr;" commanding, dignified, august. To be sure, its situation is not the very best; yet that could not be helped: but then there is one defect connected with it,

which might and ought to have been helped, [illegible] though it might not have been possible to overcome it entirely. The Hall's being placed behind the Post Office, is a matter of comparatively little consequence; because that inconvenience might, in the course of time, have been removed by improvements, which would have converted the narrow lane at the extremity of which it now stands into a wide street opening into Cheapside. It is its front being turned so very obliquely to the Post Office, which is the unfortunate and now irremediable circumstance. It affects both buildings equally, causing them to appear exceedingly shy of each other, and wheeling about in order to escape from forming any acquaintance. Were both or either of them in that flimsy "lath and plaster" style which some veracious critics assure us every one of our modern structures are built in, the mischief would be but temporary; unfortunately however, they are both likely to last for a very long time indeed. Here then, we have an instance of the carelessness or obstinacy with which buildings are erected, without the slighest regard to the further improvement of the situations they occupy; and in fact, so as to be in themselves insuperable obstructions to such improvements taking place.

Considering the building itself apart from this defect, we must admit it to be imposing in appearance, as well from the solidity of its material and construction, as from the magnitude of its features; owing to which latter circumstance, it is far more impressive than most modern works. It is not the heaviness of the enriched parts that we object to; but the insipid tameness, and even meanness of the rest, in consequence of which the whole is thrown quite out of keeping, and a solecism in architectural costume committed, which it might be imagined hardly the veriest tyro could fall into. Upon what principle, I ask, can the architect possibly defend the introduction into the same composition, of two series of windows so totally dissimilar in their character? If he considered that the one required to be so unusually ornamented, how came he to imagine that the other needed no finish at all? He may probably say that the latter are to be considered as those within a basement,—that this is plainly enough indicated by the horizontal stripes along the lower part of the front,—and that it is not very usual to give mouldings or dressings of any kind to windows occupying such a situation. He may set up such a defence; but it can avail him nothing: in the first place, the lower windows are comprised within the order, not in a basement supporting it; and even had they been so, such basement would have required to be much bolder and richer. Not only did the style he has in other respects evidently followed, peremptorily demand it; but the very circumstance of its being rather contrary to ordinary practice, rendered it all the more desirable, as tending to stamp the whole with some degree of positive originality. Even excess of decoration here, would have been the minor fault of the two. He might have enriched the exterior of the ground-floor with rustics, and by means of them alone have given sufficient finishing to the windows; or he might have distinguished them by bold dressings; or, better still, he might have adopted both modes.* Had he done so, the whole would have been consistent; but now—why! his building partakes both of the *perruque* and the *frac*, and resembles a beau in a full-bottomed wig, terminating below not exactly *in piscem,* but in a pair of nankeen trousers. While the upper part of the front decidedly bears upon it the stamp of the old architectural regime, and its stately windows with trophies and armorial bearings above them, carry us back to the days of Roman nepotism and palace-building cardinals; the lower has an air of dapper neatness and spruceness that—I am afraid the reader will accuse me of inconsistency also; at any rate of breaking my word, after giving him to understand that I should find more to approve than to condemn.

Well, let us walk in, let us pass the screen separating the vestibule from the staircase—merely noting *en passant* that it is a feature not calculated to raise our expectations to a very high pitch—and ascend the staircase itself. Here we have undoubtedly a striking architectural scene, a grand flight of steps in front (on the pedestals of which are figures representing the four seasons, by Nixon), and branching off right and left to the upper landing places, or galleries, which have screens of Ionic columns, coupled one behind the other. The columns are of Scagliola in imitation of *verde* antico; and in the centre intercolumn on one side stands a figure of the Apollo Belvidere, on the other one of a Diana. In the three intercolumns formed by the pilasters on the upper part of the wall above the stairs, or that facing the entrance from the vestibule, hang as many portraits; viz., those of George III., George IV., and Queen Charlotte. Above the entablature of the central space, are four arches, filled in with windows; over which is a coffered dome ceiling, from whose centre is suspended a magnificent chandelier. Whether viewed from below or above, the effect is both splendid and scenic, particularly when the spectator stands so as to look quite across, through all the four files of columns.

The Banqueting Hall may be entered from either side of the staircase,—therefore the reader will perhaps say it matters not which. I beg his pardon, it matters a great deal,—a very great deal indeed; therefore, should he ever have the opportunity of entering it at all, let him be especially careful to go up on the right hand side, and so enter it from the south end. He will then be struck—should the apartment be illuminated, almost dazzled—by the effulgence shed from countless wax-lights in lustres that blaze like diamonds, each gem "an empery's price." To describe their effect would almost baffle the powers, and exhaust the vocabulary of George Robins himself, who is unquestionably the greatest of our living poets, and the most imaginative of our living authors. On either side you behold a range of beautiful Corinthian columns with corresponding pilasters behind them; and at the further end, a lofty arched alcove, hung with draperies on which the light is thrown from tapers placed so as to be invisible. There too, we behold Scagliola pilasters, and between them vast mirrors reflecting the columns along the sides of the room. All is pomp and splendour; scagliola, white and gold capitals and entablature, crimson draperies, painted windows illuminated from the outside, noble doors with panels of sculpture over them, and a ceiling of very rich design. But having advanced up to the end of the room, you turn round, and half the spell immediately vanishes. You perceive an oaken or wainscot screen, supporting the gallery at the other extremity; which, though it has Corinthian columns, looks poor, dull, and heavy in comparison with all the rest. It should be observed too that the columns are smaller than the others, and instead of being raised from the floor, stand directly upon it, whereas the general order is placed upon a stylobate about six feet high. How very much better would the effect have been had the architect made the gallery,—since gallery there must needs be,—either behind columns similar to the rest, or if not columns, behind pilasters corresponding with those at the other end of the room, but insulated in the upper part of their shafts, similarly to those of the gallery in the Banqueting-room at Fishmongers' Hall. The architectural character would then have been consistently kept up throughout; whereas at present there is a decided falling off, and in that precise part too, where if possible increased display should be produced. Such most undoubtedly was the case in those halls of olden times, where we find the screen and gallery above it introduced; and which, it may be presumed, the architect of Goldsmiths' Hall had here in view. In these they were the most conspicuous feature, being frequently very richly adorned, while all the rest was left comparatively, if not positively, plain. Here, on the contrary, this portion of the design is such, that instead of in any degree heightening, it detracts from the impression made by the rest, and destroys uniformity, without obtaining for itself any pre-eminence. In short, it exhibits itself as an imperfection and a failure. The architect may be angry that any one should dare to say this; others have greater reason to be dissatisfied with him for having afforded the opportunity of its being said.

The suite of apartments on the other side of the staircase, and occupying the extent of the principal front, does not call for remark on account of anything particular in the mere architecture. They are sufficiently spacious and lofty, and they are fitted up in a costly style befitting the opulence of the company. The artist, whose talents, we here admire, is the upholsterer; luxurious carpets, rich damask draperies, and panels of the same material framed in gold, sparkling lustres, aided by candelabras, and ample mirrors reflecting and multiplying all this pomp of furniture, have their fascination for the eye, and so far impose upon a great many people that they liberally ascribe the effect thus produced to the architect himself, and give him the full credit for it; although he may have no more claim to it than the jackdaw to the peacock's plumage.

ON BUILDING MATERIALS.

NO. II.—LIME.

It is certainly well worthy of remark that, while improvement to a great extent has taken place in almost every other branch of science, the quality of the chief articles used in building should, for many years, have been rather deteriorating; our timber is generally less durable than that which was used several centuries before Mr. Kyan's patent was procured; the bricks used by the Romans are found to this day in a more perfectly sound state than in many of our edifices erected some fifty years since; and the lime and cement employed by the ancients frequently possess a durability which few of the modern inventions have

* One might almost fancy he had never looked at either the street or court front of that part of Somerset House, which adjoins the Strand. Let him imagine for a minute what kind of appearance either of those elevations would make, had its lower story such rustics and windows as those he has chosen to give his own building.

succeeded in rivalling. To this last article, so important in building, I shall confine myself to the few following observations.

Lime, as a substance for cementing together stone, &c. in buildings, appears to have been unknown to the Egyptians and the early Greeks; for most of their edifices are found without cement of any kind. Substances of a similar nature were nowever, no doubt, in use in other parts of the world at a much earlier date; in the Tower of Babel, the sacred historian informs us that they had slime for mortar; and the ruins of Babylon and Nineveh, as described by Mr. Rich, amply attest the fact of the employment of a similar substance.

Approaching however nearer home, and directing our view to less distant times, we shall find numerous proofs of the care and attention paid to this material by our forefathers. The cement used in many of the structures of ancient Rome, remains to this day firm and (to all appearance) imperishable; and the mortar employed in the construction of Richborough Castle, in the Isle of Thanet; Colchester Castle, and several of the ancient buildings of Canterbury and Rochester, is harder than the stone and bricks themselves. From this statement it must be evident that, although much has been said and written upon the subject of lime, but little improvement has taken place in its manufacture; the chief error in most works upon the subject is, that they are by far too abstruse and technical to be very serviceable to the practical man. I have frequently derived more useful information from one hour's conversation with some veteran labourer, whose experience has enabled him to point out in a rude and simple manner the properties of the various limes, than from the perusal of a highly scientific article upon the subject.

Limestone is one of the chief articles employed in the manufacture of lime: and here it should be remembered that, as each distinct kind of stone yields a particular sort of lime, so those limes are the most durable which are produced from the hardest and most durable stone. Portland stone, Bath stone, Purbeck and Painswick stone, each produce a very good lime; and Kentish rag, which is harder still, yields a lime of yet greater strength and durability. The blue lias, now so extensively used in the metropolis, is superior to any of the before-mentioned; it is particularly serviceable for concrete, and for all works that are exposed to the action of water. Its value became generally known by its use in the erection of the Eddystone Lighthouse and Ramsgate Pier, by Mr. Smeaton, where it succeeded after all other kinds had failed. It is produced from a dark-blue slaty stone, which is very plentiful at Barrow, in Leicestershire; I am informed that lately large quantities of a similar kind of stone have been found in Dorsetshire, from which much of it is now manufactured. In Wales, also, stone of the same kind is found, from which lime of somewhat better quality is made, as it is generally better burnt. For concrete, this lime is best; ground fine, and mixed with coarse gravel or river ballast, in the proportion of one part of lime to six of gravel; and it ought to be thrown immediately, and disturbed as little as possible afterwards.

Many years since, Lord Stanhope took out a patent for a newly-invented lime; of its peculiar properties I have been unable to form an estimate, notwithstanding the most diligent inquiry: it is now, I believe, but little in use.

Chalk is another substance from which large quantities of lime are produced. In the south-eastern parts of England this is the principal article from which lime is manufactured; and in London vast quantities of it are used both for public and private edifices. The chalk lime used in London, comes from Guilford, Dorking, Purfleet, Mersham, and the surrounding districts. Very little difference is observable in the quality of these limes; and although they are certainly inferior to the grey stone lime, yet their extensive use by many of our first architects and engineers seems to contradict the common opinion that they are the worst kinds in use.

In Derbyshire the vast quantities of limestone supply lime for all the surrounding neighbourhood; most of it is produced from what is termed the shell marble (referred to in a former article); it is of very excellent quality when well burnt, but is not equal to the Barrow lime of Leicestershire, when used for works exposed to the action of water. It is of an excellent colour, and slakes well; neither does it stain the stone, as many stone limes are apt to do.

Shell lime, although almost unknown in England, is extensively used in some parts of America. I have tried oyster-shells upon a small scale, and found the lime produced stand both water and fire well, but its colour is very indifferent; nevertheless I am inclined to believe that for some purposes it would be found a valuable cement, if properly prepared; its property of enduring heat would render it useful for setting ovens, furnaces, &c.

In some parts of the continent, where marble is plentiful, I am told that large quantities are used for lime, the quality of which is excellent.

It has long been my opinion that the majority of the limes made in this country are [illegible] sufficiently burnt [illegible] been supported by many persons of long and extensive practice. Certain it is, that the goodness of lime depends much upon its being thoroughly calcined; and that lime invariably slakes best which has been longest exposed to the action of the fire. In the manufacture of mortar, I think sea-sand far more valuable than most builders imagine. I am not however aware that this opinion has been entertained by many architects, although it appears that the engineers employed in the erection of the sea-wall at Brighton were of the same way of thinking. The chief objection to the use of sea-sand is, that being impregnated with a considerable portion of salt, it readily imbibes moisture. This may be in a great measure prevented, by laying the sand up in a shed, the floor of which is inclined, and frequently pouring on it large quantities of water, which when it runs off, will carry with it most of the saline particles. In the mixture of mortar, too much care cannot be taken to keep the lime from exposure to the air, as that injures its quality much more than many persons imagine; it ought likewise to be used as soon as possible after being burnt, and slaked before mixture with the sand. The process of slaking and screening is, I think, certainly preferable to grinding; as, by the latter mode, all the half-burnt stones, which form what is called "lime core," are ground up with the lime, and necessarily injure its quality. The mortar for good work should be as stiff as possible, and the bricks or stones well wet previous to setting; the contrary practice is very injurious to the durability of the lime. Road drift, which is often extensively used in the metropolis, is certainly by no means so good as fine sand, as it imbibes moisture considerably; but the mortar made from it stands heat well, and is therefore useful for setting ovens, coppers, &c.

C. L. O.

THE PARKS.

We are about to lay before our readers some remarks upon the Parks of London; and we seize the opportunity, in the first place, of remarking the very great improvements in beauty and convenience, that have recently been effected, and of acknowledging the benefits which latter administrations, but more particularly the existing commission, have secured to the public.

To those who remember the Hyde Park of twenty years past, the difference must be very striking; but even within a very short space of time, it has risen from a barren waste edged round by a narrow road, to a verdant lawn studded with well-disposed plantations, and an arrangement of walks and drives that cannot be surpassed. Kensington Gardens, too, so strikingly described by a celebrated French beauty of the day, as a "Beau triste," has no longer that sombre character. The thinning of the trees, the removal of the lower branches that impeded the circulation of air, the improvement of the walks, and the additional well-chosen approaches to them, have given a new aspect to the scene. The "lungs of the town," to borrow Mr. Wyndham's phrase, have been most skilfully treated.

But if Hyde Park calls up the recollection and elicits the comparison above mentioned, how much more will the present age gain, by comparing St. James's Park with the unadorned sameness of a former day. The genius of Nash has here been most favourably employed; and the kindness of the monarch (George IV.) who directed its opening to the public, must be gratefully felt by the crowds who daily enjoy it. The Regent's Park adds another to these instances of a less exclusive system; and the benefit will be felt in the improved health and morals of the people. By the opportunities thus afforded to the trading and operative classes, the hebdomadal visit to the suburban tavern, or the nightly relaxation of the skittle ground (to be enjoyed by the husband alone on account of its expense), is exchanged for the healthful recreation of the WHOLE FAMILY,—in fields as verdant and in air as pure, as the most opulent can command: and while the privilege thus enjoyed removes a grudge at the benefits conferred by wealth, it thereby effects a moral and physical change equally beneficial.

But though much has been done, some room may yet remain for the exercise of judgment and taste; and we offer our remarks to the attention of the authorities, so competent to appreciate them justly, and to act upon them should they appear deserving of attention.

The suggestions naturally divide themselves into two heads—beauty and convenience.

In Kensington Gardens, the former would be infinitely increased by substituting a light railing for the southern boundary wall, thereby letting in the view of Hyde Park: and the latter would be promoted by enclosing for the use of the residents of the palace, the north-west portion of the gardens by a quick-hedge, removed a few yards, but parallel to the great walk; affording, with no perceptible diminution of the public convenience, a space for private recreation. For the further promotion of the comforts of the residents and of the

public, we would recommend that a gate for foot passengers be opened from the Kensington road on a line with the door at the southern extremity of the great walk. The stream of population would, by this arrangement, be carried *from* the palace; their approach to the gardens from Kensington made more direct; and the quiet of the inhabitants promoted.

In Hyde Park, the most desirable alteration would be to cover, by a brick sewer, the almost stagnant pool (or at least the centre division) at the bottom of the Serpentine river; a delightful turf ride would thus be obtained (which might be called the Queen's ride), parallel to the gravel or King's ride; and a gate opened to it at its eastern angle near the Piccadilly lodge. It should be entirely closed from the end of September to the beginning of May, and the turf carefully attended to. A delightful ride would thus be formed for the ladies, now so generally equestrians, without the annoyance or the danger of contact with carriages.

We would further recommend the immediate removal of such trees as prevent the view from Piccadilly, of the statue erected in honour of the Duke of Wellington. This magnificent work of art—however inappropriate, or however little conveying an idea of the occasion of its erection—is yet too grand in its form, and groups too well with the colonnade, to be condemned to have its form mutilated by the intervening foliage. The trees therefore recently planted in front of it, should be removed; and, at the same time, those at the back should be so trimmed as to allow the profile always to be seen against the sky.

We shall avail ourselves of this opportunity of adding a few words upon this statue. By what authority it was miscalled "Achilles" we are not informed. By the Italian antiquaries, Venuti and Vasi, they (for there are two statues very nearly similar, on the Monte Cavallo at Rome, from one of which this is copied) are called Castor and Pollux; by Flaxman they are termed Bellerophon. But whether Achilles, Castor, Pollux, or Bellerophon, we hope—now that a second subscription has been raised for the purpose of consecrating the triumphs of the Duke of Wellington—that the sculptors of the country will not be insulted by the opinion of the committee of management, that it is necessary to import a copy from the antique. At the time of its erection we boasted the talent of a Flaxman, a Chantrey, a Westmacott, a Baily, and a Rossi: but they were not required to prepare designs; and a statue was erected, bearing no one attribute or symbol that could by possibility identify it with its object. We may too on this occasion, be warranted in giving a hint as to the material. *Of the many, many thousands of statues in bronze which decorated Greece and Italy, not one has been preserved to us;* and it should be a lesson to us *not* to employ a *valuable* material for such a purpose. Where is now the Minerva, thirty-nine feet high, made by Phidias of ivory and gold, holding a Victory in her right hand, the eyes of which, Plato tells us, were precious stones? Where the Olympian Jupiter of Elis, composed of ivory, enriched with a radiance of golden ornaments and precious stones, and esteemed one of the wonders of the world?

The valuable materials of which these works were composed might well become the object of barbarian or civil spoil; but has the baser metal, *bronze*, been more respected. The history of all times denies it. The statues on the Trajan and Antonine columns have been toppled down, and have disappeared; even where bronze has been employed on stone or marble for inscriptions, the letters have been picked out (as in the arch of Trajan, at Ancona) for their intrinsic value. In later times, the statue of Henry IV. which decorated the Pont Royal at Paris, was during the revolution cast into pieces of two sous. Our own capital offers us the same lesson;—the statue now at Charing Cross, was sold during the troubles of the reign of Charles I. for the value of the material, and only preserved as a speculation of the brazier who purchased it.

Is it too great a stretch of fancy to imagine that the statue which has given occasion to this digression, may in the lapse of ages again be cast into cannon to defend our posterity from the attacks of its former owners; or that the Pitt of Hanover-square, the Fox of Bloomsbury, and the Canning of Westminster, may mingle in the same caldron to challenge the admiration of a future age under the form of an usurping tyrant, a goddess of liberty, or a coinage of penny pieces?

As if to impress these truths more stongly upon our minds, we behold in the British Museum the marble statues which enriched the tympanum and frieze of the very temple which enshrined the splendid statue of Minerva above alluded to. Ages have rolled over them; frequent wars have desolated the city of the immortal Greeks, and slavery for centuries held them in chains; but the *marble* yet remains to attest their former greatness, and to prove to all succeeding times, that such memorials should be formed of a valueless material.

The Green Park affords a great scope for improvement, and the means of a very desirable addition to the beauty of this approach to London. The ranger's house and boundary wall should be removed, and twenty feet added to the width of Piccadilly, from Park-lane to Berkeley-street. The slope from the Reservoir to the road of St. James's Park, should be arranged in terraces and enriched with statues, vases, and bassi relievi; and some approximation thereby made to the intellectual character of the continental gardens, the Tuilleries of Paris, the Giardino Reale of Naples, and the Borghese of Rome.

The enclosure of St. James's Park is perfect; but the trees that mask the York Column from the gate of Great George-street, should be removed, thereby effecting the double purpose of opening the Park from the Column, and the Column from the Park.

From this point, (by the paternal attention of his late Majesty, William IV., to his people's comfort and convenience) we ascend Regent-street, through Waterloo-place, to the termination of our subject, the Regent's Park; and we trust we shall be excused the expression of our regrets that the opportunity of forming the most splendid street in Europe has been so entirely lost. With very few exceptions, there is here no building deserving commendation; and the taste which could have sanctioned many of them cannot be too strongly condemned. Magnificent as its whole course might have been, had the line of the High-street Oxford been kept in view, or attention paid to each succeeding vista, we have now no point at which to stop and admire its effect. Passing on to Oxford-street, we have a repetition of the circle at Piccadilly, and in front a church, which, for deformity in design, exceeds anything that has been erected during the last fifty years. As if to make this deformity more monstrous, the church is placed at an awkward angle to the street, thus destroying it as an architectural whole, and making an exposure of the baldness of its flanks and the hideous ugliness of its roof.

From hence we are unexpectedly led into Portland-place, confessedly for extent and regularity, if not for beauty, the finest street in Europe,—but how terminated? Instead of continuing by a broad road, as a principal approach to the Regent's Park, it abruptly terminates in a screen of shrubs, low indeed, but just lofty enough to shut out the view of the Park, and of the Highgate and Hampstead Hills, and to injure by their branches and foliage the bronze statue of his Royal Highness the Duke of Kent. I fear no power exists for favourable alterations in the line of street; but the power vested in the office of Woods and Forests, and so judiciously exerted at the instance of his late Majesty in opening the approach to St. James's Park by the York Column, might with equal propriety be exerted here. The carriage and footway should be continued in a straight line to the opening of the avenue in the Park, and the statue of the Duke of Kent placed on a column on the upper ground of the walk. There would then be something of character at each extremity of the line; and it is scarcely possible that it could be more properly terminated than by statues, of which that of the Duke of York reminds us of a period, when by the indefatigable attention of His Royal Highness, the army attained an efficiency that led, under the conduct of its generals, to universal victory,—and that of the Duke of Kent, to the contemplation of a Prince, who, in the sphere in which he was called upon by Providence to move, displayed a perseverance beyond all praise, in the cause of civil liberty, and the social happiness, and charitable institutions of the country. If the alteration here proposed be thought too large, and the compromise so often and so injuriously made between *what ought to be* and *what can easily be effected*, be adopted; then, most assuredly, should the statue be placed at such an elevation as would secure to it the sky for a background.

In the Park itself, we have little to propose, save the greater accommodation of the public, by opening the remaining enclosed spaces, and the addition of some ornamental architecture, affording an opportunity for placing statues, bassi relievi, and vases in various parts. The quadrupeds have indeed been turned out, and the bipeds turned in, but with just as much attention to the one as the other. The latter walk listlessly about, enjoying indeed the air and exercise; but the intellect is unemployed. The contemplation of the statue of a benefactor of mankind, either of ancient or modern times, or a basso relievo representing an historical fact, would generate a wish to be informed of the history;—the desire of knowledge would induce reading, and such occupation would remove the relish for gross pleasures. The Parks might then become spaces, adapted not merely to help the people to pass their time, but also to put them in the way of improving it; and a government so disposed, might by the substitution of such amusements for the now too much encouraged dissipation of the gin palace, be placed on the sure basis of public opinion and general happiness.

J. H.

EXHIBITION AT THE ROYAL ACADEMY.

THE ARCHITECTURAL ROOM.

Last year, the architectural department of the Academy's Exhibition was, we believe, generally allowed to be greatly inferior to what it had been for many seasons; nor is the present one more than a degree better. There are a few very good subjects; but even all those are not of a kind to afford any evidence in regard to buildings either about to be commenced or actually in progress, there being remarkably few designs for intended buildings of any importance; while there are on the contrary, several drawings of such as have before been made known to the public. For instance Mr. Vulliamy after exhibiting to us last year a large elevation for his new front of the Royal Institution, now gives us a perspective view of the same subject, notwithstanding that it is an exceedingly poor one in itself, and most common-place in its idea. There are, besides, many drawings which although exceedingly showy and captivating for their colouring and execution,—for their brilliant skies, their gay and sunny landscapes, and the effect given them by figures and other accessories, prove on inspection to have very little architectural interest, and do not display anything like equal taste and ability in architectural composition. In some of them, in fact, the colouring is pushed even to extravagance. The artists employed to furbish them up—for it is evident enough that the painter and the architect are not, in these cases, the same individual—have decked them out in dies of azure and purple, gold and emerald, and made them rival peacocks and butterflies. Indeed there are one or two things of the kind that might be still further improved by painting out the architecture altogether, that being the poorest part about them. While instead of being at all opposed to, we would rather advocate, the giving all possible effect and finish to the architecture and its details,—we would enter our protest against the interest of the subject as an architectural one, being either overpowered by or merged in pictorial display and adventitious ornament; whereby what in itself possesses neither interest nor merit, is made to seduce the eye and mislead the judgment. Not only is that which ought to be kept subordinate thus made the principal, and vice-versa, but there is another mischief resulting from the practice here censured; namely, that such specious and gaudily-coloured drawings quite overpower other drawings of a less ambitious pictorial character, and cause them to appear tame and insipid, although far better as designs, and executed with greater attention to correctness and finish of detail. Were there rooms enow to admit of one being devoted to architectural *picture-drawings*, and others to such designs as made no pretensions to rank as specimens of pictorial execution, the latter would not be seen to so great a disadvantage as they now are. In fact if it is intended that they should really be examined, drawings of this kind require a great deal of space, as they never ought to be hung either much above or much below the eye; it is moreover desirable that they should be arranged with some kind of regard to classification as to subjects and style, and not huddled together pell-mell, large and small, *exteriors* and *interiors*, Gothic and Grecian, cottages and palaces, geometrical elevations and perspective views. Any kind of systematic order is however quite out of the question at the Royal Academy, nor do the architects seem at all disposed to emancipate themselves from its trammels, and establish an annual exhibition of their own; which they surely might carry into effect did they care to exert themselves for the purpose, and set about doing so heartily. Still, we conceive, that limited as is the space allotted to architectural drawings at the academy, something might be done for their accommodation, by putting up low screens in the hall against which many of them might be hung up. What objection there could be to this we do not see: it cannot be said that the architectural exhibitors would complain of their works being thrust out of the rooms, if by being so they could be placed where they could be seen far more advantageously than within them.

That a great many cannot now be seen at all, nor would be sought for, were it not for the catalogue, is undeniable; since this happens actually to be the case with the nine first subjects there mentioned, viz., Nos. 1059 to 1067. All these may very fairly be said to be *above* criticism, being placed so high that it is quite impossible to make out what they are, so as to be able to pass any opinion on them. Even 1068 "The Entrance, Hall, at High Cliff," J. Donthorn, cannot be inspected as it appears to deserve to be. We can see indeed that it is a rich Gothic hall, with painted windows, and a lofty roof of carved timber, and that it is paved with marble in large circular compartments; but we cannot venture to speak of the minor features and detail; the kind of examination that would enable us to do so, being quite out of the question.

Nos. 1069 and 1077 are both by the present professor of architecture; but we cannot say that they make the figure the designs of his predecessor were wont to do. No one can accuse Mr. Wilkins of being inordinately ambitious to attract notice by them, both being small, and lightly tinted sepia perspective drawings, exhibiting what we at first took to be the two façades of the same edifice, till on referring to our catalogue we discovered one to be a view of Downing College, Cambridge, the other of the East India College, Haileybury. Yet they are so very much alike that the error was excusable enough. They are very little to our taste; for though it cannot be alleged against them that they are not sufficiently Greek in *their* taste, they betray too pedantic and frigid an affectation of that style carried *à la rigueur*, to show either much invention or happy conception in the application of it. There are a monotonousness and sameness of ideas in them that certainly do not evince an extraordinary stock of imagination.

No. 1071 "The Tudor Seat and Plant Cabinet at Chequer's Court," G. B. Lamb, shows how much may be made of a comparatively small and trifling subject, by intelligent treatment of it, and how much genuine character of the style proposed may be attained with scarcely anything amounting to decoration, and consequently without infringing upon economy. This and the other designs by the same architect, viz. 1126, "The Entrance Lodge at Chequer's Court," and 1142 "A Mansion to be erected in Lincolnshire," display respectively much propriety of adaptation, and a felicity in seizing upon the essentials both picturesque and architectural, of the style they profess to follow. The second, in particular, manifests no small degree of successful invention in the adaptation of the Tudor or ancient domestic style to the purposes of a modern residence; for although there is much in it for which no actual precedent is to be met with, the whole is consistent, the same expression kept up throughout, and consistency of detail—without which there can, properly speaking, be no style—well preserved.

No. 1072 "Interior," Bayley and Easthorpe, although belonging to a class of subjects much too sparingly supplied, is no very great acquisition to the exhibition. The brevity of the title bestowed upon it, leaves us quite at a loss to guess whether it is a mere design, or a view of some apartment; neither is it easy to determine its specific application. As a room, it presents nothing at all remarkable either in form, arrangement, or fitting up. On the contrary, it is not only very common-place in idea, but very exceptionable in taste. The only thing remarkable in it is the ceiling, which must be allowed to be showy enough,—gaudy rather than rich, and manifesting an aim at grandeur utterly unwarranted by any thing else; for there is not even spaciousness or loftiness, nor indeed, quality of any kind to reconcile the eye to the display it affects. Even taken by itself, this ceiling is by no means in the very best taste, having as little to recommend it on the score of elegance, as of economy.

No. 1074 "Cossey Hall, Norfolk," J. Buckler, is a subject, of which many portions have been exhibited before; and such is the variety and play of the building, so numerous are its features, that it may be regarded as a picturesque cluster of architectural studies. This is, perhaps, not the best of the series; still it contains many beautiful features, skilfully combined so as to relieve each other very piquantly.

No. 1076 "Study for the Façade of a Public Building," W. H. Leeds, although by no means a kind of drawing to attract notice, offers one or two peculiarities, more likely to be censured for boldness of innovation than for want of novelty. It shows an Ionic tetrastyle in antis, between two open screen wings of the same order, but not so lofty. It is these parts, however, that lay claim to originality, because the pillars here introduced present a combination hitherto unattempted; their bases and shafts being square, but the necking of the capitals circular, and the capital that of the usual Ionic form. The motive for making the shafts square is apparent enough, their lower part serving as antæ in the screen walls which fill up the intercolumns to about half their height. Such being the case, the only question is, wherefore then not give them corresponding capitals? The reply to which can very easily be imagined, namely that what we here behold has been done with the view of producing something decidedly new in its idea. The drawing itself is not on a sufficient scale to do justice to it; but we think the contrast of form, arising from such combination, would be sufficiently striking and perhaps not offensively harsh, the transition from the square to the circular plan being softened by the curves connecting the shaft with the necking of the capital. At all events a continued square shaft surmounted by the capital of a column is, of the two, less offensive than a column, whose shaft is cinctured at intervals by square blocks; a mode, which besides being not a little ugly in itself, is attended with increased trouble and expense. Another novelty in the design we are speaking of, consists in the tympanum of the pediment being hollowed out more in the centre than at the ends, so the figure in the middle is in full relief.

No. 1083 "Interior of the large Hall in the Building, to be called the Victoria Rooms, Bristol," C. Dyer, is so much above the eye that we can speak only as to its general appearance. This apartment, which, according to a Bristol newspaper, will be 115 feet by 55, and 46 high, offers nothing either particularly remarkable or new in regard to design. The order, which consists of coupled pilasters between the windows, looks rather insignificant when compared with size of the room itself; neither is much effect attempted to be produced by the choice and combination of colours, upon which so very much depends in interior architecture. Another very great difficulty attending a subject like this is the impossibility of showing it as it will more frequently be seen, viz. when lighted up at night.

No. 1085 "Design selected by the Committee for the new Church to be erected on Blackheath Hill," J. W. Wild, is in that very acutely-pointed early style of Gothic, which appears to be just now particularly in vogue for similar subjects, no doubt out of economical considerations, there being neither mullions nor tracery to the windows. Here we observe its peculiar simplicity without any of that meagreness and baldness that are generally so offensive in modern imitations. On the contrary, not only is the character of the details carefully attended to, but there is also a great deal of play and variety in the composition; the east end of the church (the one here shown) having two small towers, (surmounted by spires,) in each of which is a doorway, and between them the polygonal termination of the altar end of the interior, with narrow lofty windows in its upper part.

The next number in the catalogue brings us to one of the most beautiful architectural subjects in the room, "the Loggia of the Villa Madama near Rome, the design of Raffaelle D'Urbino and Giulio Romano," G. Moore. For masterly yet careful execution of an exceedingly difficult subject, replete with intricacy of details and a profusion of gorgeous colours, we have rarely met with its equal. While splendid in the extreme, it is not in the least gaudy; on the contrary it is remarkable for the breadth and repose with which it is treated. This and the drawing, by Haghe, at the new water colour exhibition, representing the interior of the "Hall of the Magistrat du Franc in the Palace of Justice, Bruges," are perfect studies in regard to execution. As

regards the architecture itself of the Loggia, it is that which deserves to be termed *par excellence* the genuine Italian style, showing all its best qualities, and none of its bad ones.

(To be continued.)

COLLIER'S PATENT BOILER.

We have been furnished by a highly respectable correspondent, with the following particulars of an experiment made to test the practical efficiency of Collier's boiler. It is designed particularly for steam navigation; and we may probably in our next number give drawings and a description of its most improved and perfect form. At present, we need only state that it is contrived with a view to exposing as great a surface as possible to the direct action of the fire, at the same limiting to the utmost the whole space taken up by the boiler. Great attention is also paid to the saving of heat usually lost by radiation; the chimney is surrounded by a jacket incasing its lower part, and containing the feed-water to supply the boiler; and the whole boiler is encased in a jacket of wrought iron, the intervening space being filled up with clay and charcoal, forming a good non conductor. Thus it will be seen that Collier's boiler conforms to some of the most important of Mr. Dinnen's suggestions which we have mentioned in another part of our Journal: the invention was patented considerably previous to the publication of the new edition of Tredgold, in which Mr. Dinnen's suggestions appeared: so that the striking coincidence between the two, proves plainly the practical utility, both of the suggestions of Mr. Dinnen, and of the invention of Mr. Collier.

The experiment, the result of which we are about to relate, was made with a boiler adapted to a fixed land engine of twenty five horse power, manufactured by Mr. Collier, at the Globe Dock, Rotherhithe, where also it is in use. Its dimensions are as follows:—

	Ft.	In.
Length	8	6
Breadth	3	8
Height to top of steam chest	9	6
Height to water line	7	6
Height of feed pipe to water line	9	6
Height of safety pipe to ditto	11	6
Evaporating surface—		
Four chambers	120	0
Crown of furnace	15	0
Two sides of furnace	50	0
Take up, bridge, &c.	65	0
Total feet	250	0

exposed to the action of the fire: which, at about ten feet per horse power = 25. Surface of fire bars 32 × 30 inches = 960 square inches; or 38·4 square inches per horse power.

The coals used were the ordinary Newcastle, of the quality generally burnt under boilers. The water for feeding was drawn from a well on the premises, into an upper cistern the contents of which had been accurately measured, and which when filled was allowed to run out into a lower cistern, whence it was pumped by hand into the jacket before described as containing the feed-water. This was uniformly kept full, and remained so at the end of the experiment. The temperature of the feed-water was then about forty-two degrees. The boiler having been at work the previous day, the fire had been banked down at night as usual. This fire having been broken up, without the addition of any more fuel the steam rose in eight minutes and a half to a pressure of four inches by the mercury gauge; at which height, or varying between that and five inches, it was kept steadily during the experiment. 1132 lbs. of coal were weighed to the stoker, who was watched closely, and kept up the fire in his usual manner. After nine hours trial, the fire on the bars being as nearly as possible in the same state as at the commencement, the experiment terminated; when the quantity of coal remaining was 260 lbs. Thus, there had been consumed

872 lbs. of coal, to evaporate 836 gallons of water, or 134·83 cubic feet,
or 1 lb. . . . . 9·58 lbs. "
or 6·47 lbs. . . . . 1 cubic foot "
or, the boiler being assumed to be twenty-five horse power, 3·428 lbs. per horse power per hour.

The boiler appeared to be very steady in its action, and the evaporation was very uniform. The stoker fired very thin and frequent charges; by far too frequent for the economical use of fuel. The coal seemed well consumed, and did not form any considerable quantity of clinker, as might have been expected from the mode of firing.

At the termination of this experiment, a trial was made of a simple contrivance adapted to the boiler, with the view to prevent either explosion or collapse. This contrivance we will shortly explain now, but our drawings hereafter may probably exhibit it more clearly. A pipe opening into the chimney at an altitude calculated for any given pressure, descends through the water space to within six inches of the bottom of the boiler. On any extra pressure of steam acting on the water, it is forced up this pipe into the chimney, where it falls into, and stops up the take-up: and, if the pressure continues notwithstanding the check thus applied, the water rises through the take-up into the fire and extinguishes it. In case of any tendency in the boiler to collapse, the action of this pipe would be the reverse; the atmospheric air would be allowed to enter from the chimney, and thus the formation of a vacuum would be prevented. Such is the contrivance: to test it, a weight was applied to the lever of the safety valve till the mercury rose to six inches and a half, when the water was forced up, and the fire extinguished. As calculated to prevent dangerous accidents, this arrangement seems worthy of general adoption: its success in this experiment was certainly complete; the fire being extinguished, as it will be seen, on the mercury rising an inch and a half, or two inches at most, above the height at which the engine had been working.

CEMENT AND TILE ROOFS.

Sir,—Your past notices of several new and useful inventions and improvements applicable to the practical part of the profession, induce me to offer the following remarks on a form of roof, not absolutely new, but little known, which recently came under my observation; the application of which, if attention be directed to it, is likely to supersede in many cases timber roofs, and may also be of great service in lieu of arched brick floors, &c.

The roof in question, covers a small building twenty four feet by twelve. On the top of the one pair walls, are laid iron plates, bolted across by iron rods; from these springs a segment roof, (versed sine 3 feet) composed of three courses of strong plain tiles in cement. It is capable of sustaining several tons pressure, and as solid as the walls themselves;—perfectly fire-proof, air, and water tight: but to give ventilation, two nine-inch gratings are inserted in the gables.

This instance must not however be taken as a just criterion of the capabilities of this form of roof; but rather as a fair specimen of its complete success, and as a proof that it is applicable to a much greater extent. Messrs. Newman's livery stables are I believe covered with a roof of this construction: the span is between thirty and forty feet, and carriages and other great weights are allowed to pass over, and are suspended beneath for repairs, without the least perceptible injury.

Upon the whole, this roof seems applicable to many uses in building; and if it be required for any extraordinary degree of strength, by placing slips of iron hooping between the courses, almost any degree of strength may be obtained. Its lightness will recommend it in many instances, where arched brickwork would be objectionable from its weight; besides allowing of a greater height between the floors. It may be used to advantage for fire proof rooms, and for endless other uses, which occur only in practice.

The roofs above mentioned were executed by Mr. Ritchie of Paddington, who appears to be the only builder who has turned his attention to this form of roof; though for some years they have occasionally been constructed flat, supported on iron girders and bearers.

I will not occupy more space in your valuable journal; but trusting this brief communication may find a place among your correspondence,

I am yours, &c.

London, May 18, 1838. C—.

[We can testify to the correctness of our correspondent's opinion, having adopted tiles and cement for flat roofs with great success: and we confidently recommend this mode of construction in preference to lead flats, where there is likely to be traffic over the top. We have also seen circular roofs constructed as described in the above communication, which have fully answered the purposes intended.]—Ed.

DUTY AND INTEREST OF CANAL PROPRIETORS.

At a period when energetic and extensive efforts are being made for the formation of railway communications, it is imperative upon the committees and proprietors of canals to come forward and render their respective navigations as perfect as possible. Many of the canals have remained in nearly the same condition for several years; are needlessly circuitous; are in a defective state of repair in their locks, towing paths, and tunnels, which latter are small, inconvenient, and even dangerous; are inadequately supplied with water, and require deepening and cleansing. It is most important that these defects should no longer remain; and that by a liberal but not improvident expenditure, the several canal works of whatever kind should be rendered effective to the increased and increasing wants and trade of the country. It cannot otherwise be expected that canals will maintain their present position, against the formidable rivalry now organizing in the midst of them.

The canal proprietors in their several districts who are so much interested, whether as shareholders or as trustees for distant parties, are bound to attend to the efficient state of the canals in their own neighbourhood; and where there does not exist in the local committees energy or inclination to effect essential improvements, it becomes the duty of the proprietors themselves, at their annual meetings, to elect such persons as are alive to the present state of canal affairs, before they irrevocably lose that portion of their trade which proper attention may now permanently secure. Good management is become an indispensable requisite to every canal company.

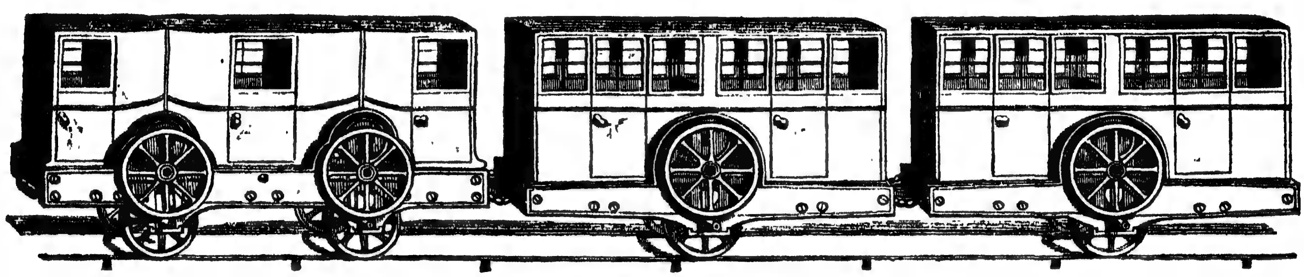
Upon some of the canals the trade is much fettered by compensation and junction tonnages, conceded in the infancy of these undertakings to the influence of opposing parties; the canal companies so circumstanced will do well, in a friendly and conciliatory spirit, to meet and arrange these antiquated modes of deriving income, and thus place their tonnages upon sound and rational footing. They will also act wisely in abolishing such local arrangements as are vexatious to the trader, and often without benefit to themselves, are injurious and irritating to the companies immediately

connected with the trade of their district. Canal companies must have no petty jealousies, but unite in affording every facility to the transit of the trade of this increasingly commercial country.

The writer of these observations is so strongly impressed with their importance, that he hopes they may commend themselves to every canal proprietor; and produce some effect upon the practical operations of every canal committee general meeting in the kingdom. Z.

[In one respect we differ from our correspondent, though we cordially assent to his doctrine that the present are not the times for canal proprietors to differ among themselves, or to be careless in their attention to the interests of those who have business on their several lines. We hope indeed that *few* canals have been constructed in situations where there is not sufficient traffic in *heavy goods* to enable them still to continue their operations with profit to their proprietors and advantage to the public. Where such is the case, the experience of the Liverpool and Manchester line is sufficient satisfactorily to prove, that with constant attention to punctuality and speed, the canals may still flourish. Yet, we fear, there are cases enough of a different character to warrant us in dissenting from our correspondent's opinion that "the several canal works of whatever kind should be rendered effective," &c. A sound discrimination, in short, should be exercised: where a railway is projected parallel to the line of a canal which does not at present pay, and is not likely ever to do so, the proprietors would do well to consider whether they might not dispose of their land wholly or in part to the railway company. And where this is impossible, rather than incur additional expense by engaging in a hopeless contest, prudence would suggest the endeavour to make their canals useful in some other way. In some cases, especially where they have large reservoirs in high grounds, might they not be converted into channels for water works, and made to supply public baths on a large scale for neighbouring towns? In agricultural districts, might they not occasionally be profitably employed in irrigation? These hints we throw out with a view to helping to mitigate the inconveniences, which must ever attend a change so vast as that introduced by the Railway System. So it always is; one improvement pushes aside the improvement which just before had superseded its predecessor: canals must now partially yield to railways; and railways themselves must quit the field when some superior invention shall appear to supersede them. Still they will have their day;—*and we rather think it will be a long one.*—Ed.]

COLES'S PATENT FRICTION WHEEL CARRIAGE.



The improvement specified, consists of a frame with a groove about half way up, in which are fitted two nuts or collars working up and down in the groove; in these collars the axles of the ground wheels revolve. The axles of the ground wheels, and of the large friction wheels, are fixed, and revolve with their wheels. But the axle of the upper friction wheel, is fixed into the frame, and screwed at the back, the wheel working round it. There is also a brace, to support the axle, and keep the wheel in its place. The axle of the ground wheel gives motion to the large friction wheel; the upper axle is met by the rim of the small friction wheel. Thus the friction is transferred from the wheel with the quick motion to that with the slow motion; the latter makes only one revolution whilst the former makes sixty. The consequence is, that where you have all the friction, there is no weight; and where you have all the weight, there is (comparatively speaking) no friction.

Another part of this invention I conceive to be equally novel and important. There is an elliptic spring buffer, acting between two cross stays upon which the springs of the carriage have their bearings; the advantage of which is, that it cannot be strained when pulling or buffing, as the spring buffer yields both ways, thereby preventing any sudden jerk or concussion. By means of a strong connecting rod made to fit the spring and fastened by a pin, is formed a continued string of rods and buffers throughout the whole train. This mode of connexion is of course indispensable when two-wheel carriages are used, and it completely obviates all tendency to tilt either way, however unequally the carriages may be loaded. There are also side chains connecting the carriages; each chain has a dovetail fastening at one end, and a spiral spring at the other. The spring will extend when the carriages turn out of the straight line; as they pull from two bearings when turning either way, and from all three when going straight forward.

The two-wheel carriages appear to me to possess a decided advantage over those with four; they are not designed to be used singly; but to be joined together in a train. My friction-wheel carriages, whether two-wheeled or four-wheeled, are evidently adapted for use with any kind of power, whether steam, horse, or hand. To test the value of my invention I have constructed various models, to which I have given motion by means of two clock-springs acting upon the ground axle of the first carriage. With this apparatus, I have made many experiments, and obtained highly satisfactory results. So that I do not hesitate to assert my belief that the above carriages will carry any weight, with less than half the power usually employed; or that they will travel twice as fast as carriages of the ordinary construction, if the same amount of power be exerted. The public however, will have the opportunity before long, of ascertaining this point for themselves, at the Adelaide Gallery; where the models will be set at work daily at twelve and four o'clock.

3, *Charing Cross.* W. COLES.

CURTIS'S TIMBER FRAME RAIL.

In laying before your readers a description of my timber frame rail, which I carried into effect in Mexico, on a large scale, in the year 1835, and of which the accompanying drawing is a perfect representation, I cannot do better than state my experience of the exceeding value of the cross sleepers, or ties; as their use has been publicly called in question by an engineer, whose opinion is entitled to some deference. The railway in question was laid down the side of a hill, at an angle of 30 deg. I cut into the hill on one side, and the outer side, or wall, was formed with stones, *cemented* with mud: a usual mode of building rough walls in that country. The void left between the wall and hill was filled in with the debris of the rock, resulting from the side cutting; the frame was laid upon this seating, the outer end of the cross timbers resting upon the wall; and the rails were packed up with the rough stone. Although this embankment, if I may so term it, was formed of the most loose materials, yet such was the security produced by the continuous frame, that during my residence at the mine, it never failed once; and I have received advices during the latter part of the past year, that it answers perfectly. The machine of which it forms a part has also been at work from the day I set it in motion, without any material accident. The great value of a timber frame rail is, that it forms a kind of web, which—laid upon the top of an embankment—tends to hold it together; because a train passing over it cannot affect one part without the contiguous parts bearing a certain proportion of the load. The effect of a train passing over a timber, or a rail and stone blocks without ties, is to press them into the soil vertically, and the timbers or stones act as wedges to push out the soil, and to cause those side slips which so frequently take place upon a new embankment. But the effect of a train passing over a timber confined by transverse ties, is very different; the ties in this case act as the radii of circles, of which the outside rail on the opposite line of rails is the centre. The effect then of the load will be, to press the rails in the direction of the circumference of the circle, or towards the centre of the embankment. Again, in the event of a slip taking place, a timber without ties would be pushed outwards by the wheels, and the train would run off the line, and in fact the rails have a perpetual tendency to get out of gauge; but when confined by ties, this is not the case; and if a slip does take place, the rails remain in a comparatively perfect state. It is objected to the cross ties that, inasmuch as they form a more solid bearing than is obtained at the intermediate points, the line is soon formed into a series of undulations; but any person of the least discernment who has noted this circumstance, ought to have seen the remedy in the defect itself; it only requires that the cross ties should be placed at less distances from each other. In my rail, I always place the timber on the edge; because, in the first place, its stiffness is as the square of its depth—so that what is lost in a narrower bearing surface, is more than counterbalanced by the stiffness of the timber; and, besides this, it enables me to form the joint in a more advantageous manner. In cases where the timber is very long, I place two, or three, or more cross ties between the two corresponding rails, and not across the whole four.

Fig. 1.

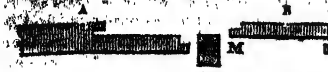


Fig. 2.

Fig. 3.

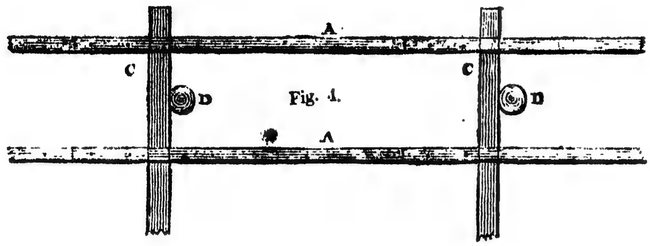

Fig. 4.

The construction of the rail will be readily perceived by reference to the engraving. Fig. 1 is a side view of the end joints of the timbers A and B; the tongue of B enters the notch of A, and the two tenons, one in each timber, enter the mortice M of the cross tie C, and meet midway, forming a joint, as shown in fig. 3, which is a side view of the rail. When thus formed, two pegs or trenails, shown by the dotted lines, are drawn through the joint, and it is finished. Thus the two timbers and cross sleeper are united at one operation, and in a manner so perfect, that they can never twist or get out of shape; and one timber has a tendency to correct the twist of the succeeding one. Fig. 2 is a front view of a cross tie, with the mortices for the tenons of one line of rails. Fig. 4 is the plan of the frame; A A are the rails; C C the cross ties; D D are piles or wedges of hard wood, which I let into the rock, to prevent the frame from sliding down the hill. I had no notion of using them otherwise than as stops, and not to hold down the frame to the ground; this idea is due alone to Mr. Brunel, and I have no doubt will be found exceedingly useful. W. J. CURTIS.

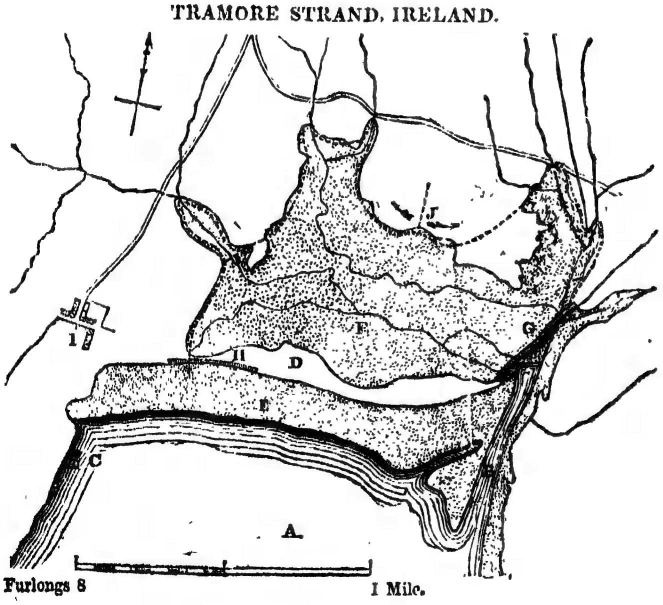
TRAMORE STRAND, IRELAND.



References to the Map.

A, Tramore Bay as it appears at low water.—B, Rhineshark Channel.—C, Proposed Pier.—D, the Burrow, or neck of land, dividing the Front and Back Strand.—E, Front Strand of Tramore, which is covered at high-water.—F, the Back Strand, now covered at low-water, which it is proposed to embank in, and thus reclaim.—G, Embankment to be made.—H, Sea-wall to be erected to strengthen and protect the narrow and weaker portion of the neck of land between the two strands.—I, the town of Tramore.

The dotted lines show the new catch-water drains which it is proposed to construct, to carry off the water flowing from the rivers. The summit level of these drains is at J, from which point they fall to the East and West, as shown by the arrows. The Eastern drain discharges itself at the embankment G, just below high-water mark; and the Western one flows out at the sea-wall H.

Extract from the Report of William Bald, Esq., Civil Engineer, for embanking and reclaiming 1,425 Acres of Land.

"The Back Strand of Tramore is, in strict geographical language, a gulf; but at low water it is dry. It is connected with Tramore Bay by the Strait of Rhineshark, which is 322 yards broad at high-water spring tides, and 113 yards wide at low-water. This strait and channel bear seaward from the Pool of Rhineshark S.S.W. ¾ W.

"The south side of Tramore Back Strand is defended from the run of the ocean by a very remarkable spit or peninsula of land, two and one quarter English miles in length, commencing on the west side, within three furlongs and a half of the town of Tramore, and extending to Cape Ottrington at the Strait of Rhineshark. This peninsula is, in its narrowest part, 170 yards wide, and is only about five feet six inches above high-water spring tides, and on the surface consists of shingle. In its extreme breadth, it is 480 yards across, consisting of sand-hills rising from twenty to fifty feet high. This peninsula, on the sea side, presents an immense beach, consisting principally, on the surface, of sand and shingle, but in several places underneath, clay, and even bog is found, containing trunks of trees.

"The Back Strand of Tramore contain 980 Irish acres, or 1,588 English acres. The surface of all the upper creeks consists of beds of mud, and a very considerable portion of the Back Strand is covered with rich alluvial deposits, combined with marine exuviæ; but towards the Rhineshark, the surface is composed of sand. In several places, considerable quantities of cockles are to be found. The nature and extent of the whole surface of the Back Strand, with the strata underneath, have been minutely described and set forth in the Map which accompanies the Report, and the various rivers and channels by which it is intersected, and also the depth of water over it at high-tide, has been stated.

"Adjacent to the Back Strand, on the coast edge of the church lands of West Kilmacleague, are 40 acres, 1 rood, and 21 poles of marsh land; 20 acres, 2 roods, and 30 poles in the lands of Lisselan; and 5 acres, 3 roods, and 12 poles in the lands of Ballynattan. These pieces of ground containing 66 acres, 3 roods, and 13 poles Irish, or 108 acres, 1 rood, and 1 pole English are covered by the sea at high-water, but could be readily converted into excellent productive land if embanked in from the influence of the high tides. These marsh lands consist of compact bog and alluvial deposits; the retentive nature of this kind of soil would form one of the best and most permanent puddles that could be used in the construction of engineering works, such as hydraulic dykes, and particularly where embankments require to be made quite impervious to water.

"There are on the Burrow side of the Back Strand of Tramore 46 acres, 2 roods, and 16 poles Irish, or 75 acres, 1 rood, and 37 poles English, of ground called marsh, covered by the sea at high-tide; but it is a soil of a light nature, consisting partly of alluvial deposits mixed with sand.

"The Back Strand of Tramore is surrounded on the east, north, and west, by an arable country, undulating and moderately high; and as the quantity of water flowing into the Back Strand from the adjacent country is an important element connected with the proposed drainage and embankment, I have, therefore, made the following calculations of the quantity.

The Width, Depth, Velocity, and Sectional Area of the Rivers and Brooks running into Tramore Back Strand, as measured on the 26th of January, 1838.

	Breadth of Rivers and Brooks.	Depth of Rivers and Brooks.	Mean Velocity of the Rivers and Brooks.	Sectional area of the Rivers & Brooks.	Quantity per min. Cubic feet.
	F. D.				
1. Crobally	21. 0	0.333	Weir 21 ft. wide	6.93	257
2. Pickardstown	4. 0	1.333	34 ft. 5 in. in 22sec.	5.32	500
3. Drumcannon	2. 0	1.41	6 ft. in 8 sec.	2.82	126
4. Cuilla	4. 0	0.50	15 ft. in 7 sec.	2.00	257
5. Lisselan..........	3. 0	0.333	14 ft. in 21 sec.	0.99	39
6. West Kilmacleague	2. 41	0.25	12 ft. 5 in. in 10 sec.	0.60	45
7. North Ditto	10. 0	0.50	23 ft. in 10 sec.	5.00	690
8. South Ditto	5. 5	0.25	11 ft. in 10 sec.	1.37	90
				25.03	2004

Thirty-three cubic feet per second. The mean quantity daily given by the general calculation, as stated in this Report, is twenty-five cubic feet per second.

"The velocity of the surface of the sea-water in the middle stream at half-flood spring-tide, running inwards to the Back Strand through the Rhineshark Channel, on the 27th January, 1838, was three miles and 480 yards per hour, or 4.80 feet per second. And the velocity at half ebb spring-tide, running outwards from the Back Strand, through the Rhineshark Channel, on the 29th January, 1838, was three miles and 1432 yards per hour, or 5.59 feet per second.

"The greatest depth of water found in the Rineshark Channel at low-water, on the section taken across, was 13.7 feet; and 25.7 at high-water.

Sectional Area at low-water	. . . .	2,924 superficial feet.
Sectional Area at high-water	. . . .	11,004 superficial feet.
Mean hydraulic depth at low-water	. .	8.54 feet.
Ditto . ditto at high-water	. .	11.92 feet.

"Taking the area of the Back Strand at 980 Irish acres, and assuming the mean depth of the water from the soundings and levels at five feet at ordinary spring-tides high-water, there will be (70560 × 5 = 352800 × 980)

345,744,000 cubic feet of water, with which the Back Strand is filled twice in twenty-four hours during ordinary spring-tides. Although this water does not consist wholly of sea-water, yet the influx of so great a quantity of water into the Back Strand must cause a considerable indraught into Tramore Bay, which seriously affects ships falling within the headlands of Brownstown and Newtown; indeed, so much so, that a vessel has never been known to be able to work out again, when once unfortunately within the influence of this indraught current. Therefore, the construction of any works that would diminish this indraught into Tramore Bay, and prevent the frightful loss of life and property incurred by the wrecking of so many ships within Tramore Bay should be hailed as a national advantage to the shipping interests of the empire. The shutting out of the tidal waters from the Back Strand would diminish to a great extent the indraught into the Bay of Tramore, so dangerous to the mariner.

"The Harbour or Pool of Rhineshark contains at low-water an area of about six acres, and a depth from eight to thirty-five feet, with good holding ground, and is well sheltered. There are several fishing-hookers belonging to this harbour; they generally lie in a creek three-quarters of a mile above the Pool of Rhineshark, between East Kilmacleague point and Carbally, and which place is dry at low-water. The length of the channel from the Pool of Rhineshark to its entrance seaward is one mile and three furlongs. The depth of water on the Bar at low-water spring-tides is about one and a half feet. The entrance is narrow and difficult, being neither marked by buoys nor perches, and should never be entered by even small vessels without having a pilot on board.

"Having described the extent and nature of the soil of the Back Strand of Tramore, the average depth of water on it at spring-tides, the quantity of water flowing in upon it from the high land which surrounds it, and the velocity of the sea-water flowing in and out at half-ebb and flood spring-tides, through the Straits of Rhineshark; also the sectional area and mean hydraulic depth at high water and low water, at the narrow entrance of Rhineshark; it is now necessary to describe the situation and nature of the works to embank in the Back Strand of Tramore.

"An embankment across the Straits of Rhineshark would be shorter than any other embankment which could be constructed to shut out the tidal waters, but its construction would be attended with great expense, difficulty, and risk, on account of the strong and powerful current through those narrow straits. Such an embankment across the Rhineshark at Cape Ottrington would entirely destroy the Pool and Harbour of Rhineshark, which it seems to be so very desirable to preserve, if it be possible, in any plan for embanking in the Back Strand. I have, therefore, proposed to construct an embankment from near Cape Ottrington to the east point of Kilmacleague, as drawn on the map, and which will leave the present Pool and Harbour of Rhineshark open, so that boats can still lie up in the creek between east Kilmacleague and Carbally. The extent of the Back Strand inside this embankment, including marsh land, will amount to 1,425 English acres. This proposed embankment is 1,325 yards long, twenty feet wide at top, and armed in front with a stone wall or pavement battering. It is proposed to have two or more sluice gates to discharge the land-waters into the sea during low tide; but before constructing such an embankment, it would be desirable to lay down a rough rubble stone dyke in the line of the proposed embankment, only a few feet in height, which would cause an accumulation of alluvial deposit behind it on the Back Strand; and one year's trial would show the amount of this deposition, which in my opinion would be found extremely valuable in enriching the surface parts of the Back Strand, where sand exists. In Holland, stakes are driven down in the line of the proposed embankment, and a kind of fence is constructed with willow twigs and branches of trees, a few feet in height, by which the floating alluvial matter is intercepted and deposited on the land intended to be embanked in; by this mode of proceeding, the surface is not only raised higher by these accumulated deposits, but forms a soil of the richest and most productive kind.

"In order to prevent the sea from flowing over the shingle beach into the Back Strand, and also to strengthen and secure the beach more effectually from the inroads of the ocean, I have proposed that a rubble pavement should be constructed, sloping seaward, and secured at the toe with a row of small sheeting piles; the lowest portions of the beach need only be secured, which is about 880 yards long, but the whole length is 1500 yards.

"At the western corner of the beach a small tunnel and sluice gate is proposed to be constructed, to discharge the waters from the catch-water drain, and which will receive the waters from the high land which bounds the Back Strand on the west side. It is intended to surround the whole Back Strand with a catch-water drain, to receive the waters which may flow in from the high land which surrounds it.

"All the parts of the Back Strand which are covered with mud will become extremely productive land; and even the parts which are of a sandy nature can be fertilised and covered with alluvial depositions, by confining the fresh water upon it for some time, as already described. There are about 324 acres of mud; 686 acres of mud and sand, mixed; and 232 acres of sand and gravel; which I would value at the following rates, annually, after being embanked in and under cultivation:—

ACRES.		£	s.	£	s.
324	of Mud	at 2	0	648	0
686	of Mud and Sand	at 1	10	1029	0
232	of Sand and Gravel	at 1	0	232	0
				£1909	0

ACRES.		£	s.
	Brought forward	£1909	0
108	of Marsh land	216	0
75	of Ditto	75	0
1425	Total English Acres.	£2200	0

"Looking at the facility which the physical structure of the shore presents to embank in Tramore Back Strand; at the elevation and rich nature of its soil; its fitness and capability from practical experiment to produce a succession of the most luxuriant crops for a long period of time without manure; the climate so favourable to vegetation; its contiguity to the market of the city of Waterford; and, looking in general at the immense return and value of the lands embanked in from the sea, both in Great Britain and on the Continent, compared with the outlay of capital,—all this satisfies and assures me, on considering the various circumstances, that the Back Strand of Tramore would more than amply repay the capital invested in embanking it in and improving it. No part of the sea-lands of Ireland offers a more inviting field to repay the industry and enterprise of man; it would also afford employment to the labouring classes of a more useful and permanent character than the construction of a railway, a canal, a harbour, or a road. Those useful and national works, the accompaniments of extended trade and wealth, create, during their execution, a very considerable number of labouring men, but who are left frequently without employment when those works are completed: whereas tracts of lands when drained and embanked, not only give useful employment during the execution of those operations, but they also afford permanent employment to labouring classes in the general cultivation of the land so drained or embanked, and it is in this respect that works of drainage and embankment are more pre-eminently calculated to benefit the poor in affording useful and *lasting employment* than either harbours or canals, &c., &c.

"The sea-lands covered with mud which have lately been embanked in from the sea, in the estuary of the Forth, on the estate of Lord Dundas, in Scotland, have been valued at five pounds per acre. It has been stated to me by the agent, that those lands will give twelve crops of wheat without manure; and it even has been asserted, that this sea-mud land is so rich that it would give alternate crops of wheat and beans for twenty years without requiring to be manured; 300 acres have been embanked in at a cost of forty pounds per acre; and there are about 1,300 acres capable of being taken in. The embankment constructed is eighteen feet high in several places, and has been faced with stone. In Scotland several tracts of sea-land have been recovered from the sea, and also lakes drained, which are unnecessary to detail; and even some of them in the most remote parts of that country, viz.: in the Isles of Islay, North Uist, and Borcray; these tracts have most amply repaid the expense of embanking. On the Continent, lately, the Polder of Snaerskerke, near Ostend,* containing 1,300 acres, was embanked in from the sea; it was afterwards divided into fields of about thirteen acres each, and it is now worth more than sixty thousand pounds sterling."

Estimate of Embanking in the Back Strand of Tramore.

	£	s.	d.
WORK ON FRONT BEACH.			
880 lineal yards of beach to be raised and armed with stone, 20 yards broad and $1\frac{1}{2}$ feet thick, $880 \times 20 \times .50 = 8,800$ cubic yards, at 4s.	£1,760	0	0
880 lineal yards of piling along toe of paving, each pile, 7 feet long, 4 inches diameter, 9 piles to each lineal yard, 7,920 piles at 1s.	396	0	0
Tunnels, with sluice-gates through the beach	350	0	0
EMBANKMENT FROM NEAR CAPE OTTRINGTON TO EAST KILMACLEAGUE POINT.			
1,325 lineal yards of embankment, 5 yards high and 12 yards broad, $1,325 \times 5 \times 12 = 79,500$ cubic yards, at 6d.	1,987	10	0
Puddle wall in centre of embankment, 15 feet high, 6 feet thick, and 1,325 yards long. $1,325 \times 2 \times 5 = 13,250$ cubic yards, at 2s.	1,325	0	0
Arming 1,325 yards long of embankment, average measure along face of pavement, 7 yards and 1 yard thick. $1,325 \times 7 \times 1 = 9,275$ cubic yards, at 10s.	4,637	10	0
Parapet, 1,325 lineal yards long, 4 feet high, and two feet thick. $\frac{3,975 \times 4 \times 2}{27} = 1,177$ cubic yards of solid masonry, at 8s.	470	16	0
Cut-work in two tunnels, with sluice-gates, iron-work, &c.	800	0	0
Carried forward	£11726	16	0

* "Before any operations were commenced, Buonaparte personally examined this Polder, and investigated the practicability of recovering it from the sea, and improving it. The chief embankment to shut out the sea was 480 yards long, 15 feet high, 10 feet broad at top, and 30 feet broad at bottom, and cost 40,000 francs; the land of this Polder is let at the rate of nearly three pounds per English acre. The usual rotation of crops are oats, rape, or winter barley; winter barley, pease, beans, or tares.

"The Polder lands require no manure; but after being cropped for upwards of thirty years, they are then laid down in grass. It is considered, in Flanders, that the tillage of the Polder soil might be continued for fifty years without manure, if care be taken to let the grain crops be alternated with those of a leguminous kind."—*I have merely mentioned this circumstance, because a great part of the soil of the Back Strand of Tramore bears a striking similarity in its composition and richness to that of the Polder of Snaerskerke.*

(*Signed*) WILLIAM BALD,
Dublin, Feb. 1838. *Civil Engineer.*

[In our next number, we will give the sections of the drains and embankments; also the calculations of the discharge of water from each of the catch-water drains, and the different rivers flowing into the bay; as well as other particulars connected with the subject.]

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

Report of Papers read and Proceedings, Session 1838.

(*Continued from page* 200.)

Additional Remarks on the Canal Lifts of the Grand Western Canal, by James Green.

If the trade of the canal were all downward, there would, by the use of these lifts, be carried from the lowest to the highest level of the canal a quantity of water equal to the loads passed down.

Mr. Green stated, in reply to several questions, that in some parts of the canal it had been found impracticable to get a sufficient drain to empty the chamber—they were compelled therefore to use a half lock of eighteen inches' fall; that there were seven lifts and one inclined plane on the canal, effecting a rise of 262 feet in eleven miles. That he should not recommend them as applicable to boats of more than twenty or thirty tons. The width of larger boats was an obstacle. They were extremely advantageous for narrow canals; for boats of fifty or sixty feet in length, and about thirty tons.

Mr. Parkes remarked, that he considered the question of narrow canals as a most important one—the advantage to be derived from narrow canals was a subject to which sufficient attention had not been paid.

The President called attention to the remark in Mr. Green's paper, respecting the quantity of water carried up from one level to another in a downward trade wherever those lifts are used; then a coal country on a high level may supply itself with as much water as it sends down coal. The subject of inclined planes being alluded to, especially those of the Morristown Canal of 200 feet each, where a rise of 1,600 feet is effected by eight inclined planes, Mr. G. remarked that more water and time must be expended, the friction and length being much greater. In the lifts there was only as much water consumed as was equal to the load, but that he should not consider them as practically applicable to more than sixty or seventy feet. Favourable levels with ascents of more than sixty or seventy feet could seldom be found; could he have had the choice of the line in this particular instance, he should have effected by four lifts the rise for which seven are now employed.

Professor Willis, on the Teeth of Wheels.

The geometry of this subject may be considered as complete, but it appears that important additions may be made to its practical applications. The general problem is, having given a tooth of any form, to determine one which shall work correctly with it. The method of effecting this may be shown in a simple practical manner. The curve to be traced out, which is the shape of the required tooth, is the locus of the intersections of all the outlines of the tooth in every one of its positions. The motion produced by the mere contact of the curve so traced out with the given tooth will be uniform. This then is a practical mode of showing the practicability of the problem.

The epicycloids and involutes have hitherto, from the facility with which they can be described, been almost universally employed, and practice has been confined to the class of epicycloids which work correctly with straight lines or circles. The defect under which such wheels labour is, that a wheel of fifty teeth of the same pitch will not work correctly with a wheel of one hundred teeth of the same pitch; since the diameter of the describing circle by which the epicycloid is formed, must be made equal to the radius of the pitch circle of the wheel with which the teeth are to work, and will therefore be twice as large in the second case as in the first. Also, if the teeth be epicycloids, generated by a circle whose radius is equal to that of the wheel with which it is to work, which is equally correct, the same remark applies.

This defect was of no great consequence when the teeth were wooden; but it is of great consequence in iron wheels, since the founder must have a new pattern of a wheel of forty teeth for every combination that it may be required to make of this wheel with others. It is desirable that the teeth of wheels be formed so that any tooth may work correctly with any other of the same pitch. This is the case with involute teeth, but the obliquity of the action is an objection to their introduction. The requisite property may be given to epicycloidal teeth, by employing the following proposition. If there be two pitch circles touching each other, an epicycloidal tooth formed by causing a given describing circle to roll on the exterior circumference of the first, will work correctly with an interior epicycloid formed by causing the same describing circle to roll on the interior circumference of the second.

From this Professor Willis deduces the corollary, that if for a set of wheels of the same pitch, a constant describing circle be taken and employed to trace those portions of the teeth which project beyond each pitch line by rolling on the exterior circumference, and those which lie within it by rolling on its interior circumference, then any two wheels of the set will work correctly together.* This corollary is new, and constitutes the basis of the system already alluded to.

It only remains to settle the diameter of this constant describing circle. The simplest considerations serve to show that the diameter of the constant describing circle must not be greater than the radius of the pitch circle; hence, as a convenient rule, make its diameter equal to the radius of the least pitch circle of the set. This rule is perfectly general, applying to racks and large wheels, as well as to annular or internal wheels. The simplicity of this above the old system is obvious, for on the old every epicycloid requires two circular templets; also there must be as many templets as pitch circles in the set, whereas on this system but one describing templet is required.

For machinery in which the wheels move constantly in the same direction, the strength of the teeth may be nearly doubled for the same quantity of material, by disposing it so that the backs are an involute or the arc of a circle, the acting faces being of the usual form.

In the preceding the exact forms have been described; the author then proceeds to ascertain forms sufficiently accurate for practice, and which are arcs of circles. Euler suggested the substitution of arcs of circles of curvature instead of the curves themselves. The portion of a curve employed in practice is so small that a circular arc is sufficiently accurate, provided the centre and radius with which it is struck be determined by some more accurate method than by mere trial. With this view Professor Willis was led to investigate a method in which the nature and properties of curves proper for teeth are entirely neglected, and a simple construction shown by which a pair of centres may be at once assigned for a given pair of wheels, whence arcs may be struck that will answer the purpose of enabling these wheels to work correctly together.

The nature of the motion produced by the pressure of one circular arc against another, is then examined and reduced to that of a system of three rods, the middle one of which is jointed to two others, moveable at their other extremity about a fixed centre; and a simple construction is arrived at by which we may always find a pair of centres from which two circular arcs may be struck through any point, which will drive each other truly for a small distance on each side of that point. This point, when the side of a tooth consists only of a single arc, should be on the line of centres. It is however more advantageous that the tooth should consist of two arcs, for then there will be two points at which the action is exact—one a little before reaching the line of centres, the other a little after passing it.

From these investigations the author was led to construct an instrument for setting out the teeth of wheels, which may be used with perfect facility by the workmen, and which has been termed an Odontograph; the application of which is fully described. The paper contains many practical observations connected with this subject, tables, &c., and concludes with some directions for ascertaining the correct form of cutters.

On the Ventilation of Tunnels. By W. West.

This paper contains an account of some experiments on the temperature of the air in a tunnel on the Leeds and Selby Railway. There are three shafts in the tunnel; and Mr. West observes, the temperature of the external air being thirty-four degrees, the temperature at the mouth and as far as the first shaft was thirty-four degrees and a half, but that immediately beyond this shaft it rose to thirty-five degrees, and increased uniformly up to the farther end, at which point it was fifty-seven degrees. From this fact the author infers that the air passed up the shaft, and that the tunnel would be more completely ventilated without any shafts; and that shafts generally are an impediment to perfect ventilation.

Wordsdale's Method of Transferring Letter Bags.

The apparatus invented by Mr. Wordsdale for changing the letter bags on the railways without diminishing the speed at which the carriages are travelling, is exceedingly simple. The bag to be taken up is hung on an arm projecting from a post, generally a lamp post; and the bag to be left is suspended at the end of a rod projecting from the back of the railway carriage. The guard knows the exact distance to which the rod is to be pushed out; and the projecting iron of the lamp-post receives the bag to be left at the same instant that a projecting iron on the guard's rod sweeps off the bag to be taken up. This exchange is certain, and effected without any loss of time.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

It affords us much pleasure to be able to lay before our readers the following report, as we heartily agree with every word it contains; especially would we mention, as deserving of high commendation, the part relating to the

* For there is both before and after passing the line of centres an exterior epicycloid working with an interior epicycloid; for before passing the line of centres, the part of the driving tooth *within* the pitch line works only with the portion *without* the pitch line of its follower; and after passing the pitch line, the part of the driving tooth *without* the pitch line works with some portion of the following tooth which is *within* the pitch line.

Council having provided a series of lectures upon various subjects connected with construction. The lectures that have been delivered this session have been of the most valuable description: not only interesting, but of practical service to the profession. We sincerely hope they will be followed up every session with lectures equally valuable.

REPORT OF THE COUNCIL

Presented at the Annual General Meeting held 7th of May, 1838.

When the Council in May last made their Report, it might have been thought that topics of congratulation were exhausted in the enumeration of the successful results attending the formation and subsequent proceedings of this Institute, which had then acquired stability and importance from the Charter of Incorporation granted by his late Majesty William IV. The Queen, however, with that love for Art and Science which has distinguished the very first year of her Majesty's reign, has been pleased to become the patroness of this institute,—at once placing us on a footing with the most distinguished Societies of a similar nature in the empire. This honourable distinction renders it a duty still more incumbent upon the members to promote the objects of the Institute by their personal co-operation, and the contribution of communications. It is by such means only that the body can continue to merit the august patronage which has been so graciously conferred. We must emulate the zeal with which other scientific Societies are pursuing their researches, and like them contribute to the advancement of knowledge, and a more general diffusion of the true principles of taste and science.

The removal of the Institute to apartments at once more convenient, and in a more desirable situation, has been productive of a larger attendance of members and visitors at the ordinary meetings. This circumstance, together with the additions constantly making to the books, models, and casts, prove that the rooms previously occupied would have been totally inadequate to the accommodation now absolutely necessary. The constant accession of new members, and the conviction that the progressive increase of the Library and Collection would outgrow even the present apartments, induced the Council to repeat their application to Government for accommodation in some public building. The Council considered that the present state of the Institute rendered the renewal of the application made in 1835 not inopportune. This application was, as you are aware, again unsuccessful. The Council, however, cannot but consider that the question of such assistance being rendered to public Scientific Bodies acquires strength in the public mind, and that the Government will at length feel itself justified in acceding to the reasonable expectations of those societies, and thus promote, by their countenance and support, the advancement of objects which are not merely of interest to individuals, but highly important to the nation.

The Council have thought it necessary this Session to provide series of lectures, as complete as possible, upon various subjects connected with construction, not only for the purpose of general information, but to show that the Institute is aware of the advantages which must result to Architecture from every department of Science being made to bear upon the main object and purpose for which it is founded. The number of such courses is limited only by the pecuniary means of the Society, but the Council trust that the funds may allow the continuance of the same system of instruction, and that each Session may be distinguished by the delivery of fresh series, as satisfactory as those to which the members have listened with so much pleasure and improvement. There is a wide field still open, and, independently of the history and theory of Architecture as an art of design, there are acoustics, optics, mechanics, and other subjects, forming parts of the necessary practical education of the Architect, which still remain to be considered. It is no less a matter of congratulation that professors of distinguished merit should be induced to consider their respective sciences, not merely in an abstract point of view, but in reference to their useful application to our art, which involves the comfort, the health, and consequently the happiness of every class.

The result of the competitions for the medals offered by the Institute, has this year been most satisfactory, and has led to the institution of an additional medal of merit, in order that the author of one of the unsuccessful designs, which evinced considerable talent, might receive a mark of the approbation of the Members. This medal may be awarded in future also to those drawings and essays which, although distinguished by much merit, have not the first medals adjudged to them. The successful manner in which the subject of the Restoration of a Conventual Building has been treated, has confirmed the Council in their opinion of the propriety of calling the attention of the Architects scattered over the United Kingdom to our national antiquities, confident that the timely investigation of these remains, so deeply interesting to us as Englishmen, will rescue them from that oblivion which might attend the neglect of a few more years. Thus we shall have ere long an important accumulation of authentic documents and information upon the monuments, the taste, the skill, and the customs of our ancestors, valuable not only to the Architect, but to the Antiquarian, the Artist, the Historian, and the Philosopher. We thus at once enrich our collection, and pay a debt of gratitude to those, from the contemplation of whose works we derive so much instruction and delight. At the same time, it is highly important that we should not allow our national predilections to lead us to neglect the classic works of the ancients. It is therefore to be hoped that one of the subjects proposed for the Prizes in each year will continue to be devoted to Greek or Roman Architecture. The investigation of the principles, which guided the masters of antiquity, is essential to the student, and opens sources of the sublime and beautiful, indispensable to him who would distinguish himself in the art. His perception and powers must be necessarily restricted; who can reject, as unworthy his notice, the resources and suggestions which each style offers. The architecture of every period and of every nation has its limits and its peculiar beauties—for although it would appear that there is a point of perfection beyond which the skill of man cannot go, so there is no period in the history of any people in which the taste is so degraded, no country so lost in barbarism, where (if the mental faculties be vigorously exercised) the productions are undeserving attention, and entirely devoid of some characteristic quality.

The report then proceeds to state the number of Fellows and Associates that have been elected since the last annual meeting, and also the reciprocal good feeling that has been kept up between the institute and their brother architects in various parts of Europe. The state of the finances is next exhibited, and the report very properly concludes with the following exhortation :—

Hitherto the Institute has flourished beyond the most sanguine hopes of its founders, but we must not rest satisfied merely with what has been already accomplished. An important sphere of duty attaches to the position which we have been called upon to assume, by the wishes of the profession, by the necessities of the art, and the improving state of those departments of science, the application of which is so important to construction. Its members, therefore, are bound to work out the objects of its foundation, to investigate every branch of art and science connected with architecture, and thus to keep alive the interest now felt in our proceedings. To preserve the continuance of that support which we have already received from the learned, the wealthy, and the noble, we must make this an active and efficient Society, and not rely upon a mere name. Each member must reflect that the Institute is in a degree dependent upon his personal assistance. It is by a combination of individual efforts alone, that any value can attach to its proceedings, and that Architecture in its widest sense can profit by our association. Let every member, therefore, at the end of each Session, put this question to himself—"What have I contributed to the Institute during the past year?" and let him consider whether his answer be commensurate with the position which he holds in society and in the profession, and whether he has fulfilled the pledge given by him in the declaration which he signed upon his admission, "that by every lawful means in his power he will advance the objects of the Institute."

At an Ordinary General Meeting of the Members, held on Monday, the 21st of May, 1838.

H. E. KENDALL, Esq., Fellow, in the Chair.

The following gentlemen were elected. As Associate;—George Edward Laing, Esq., of 5, Charlotte-street, Bloomsbury. As Honorary Member;—J. G. Wilkinson, Esq., author of various works on Egypt. As Honorary and Corresponding Members; Signor Valadier and Signor Camvia of the Academy St. Luke at Rome; Herr Hessmer, Professor of Architecture, Francfort.

Letters were read from the Secretary of the Academy of Fine Arts, at Florence, acknowledging the receipt of the Society's Transactions; and from the Signor Rizio Rangalè at Athens, acknowledging the receipt of the Society's Rules and Regulations; the latter accompanied by copies of the Archeological ephemeris of Athens, three parts. From Signor Rangalè's letter, it appears that the veteran M. Fauvel, the well known French Consul at Athens has paid the debt of nature at Smyrna. This remarkable man left Athens when the Greek revolution broke out, and has since that time constantly resided at Smyrna. His knowledge of antiquity was remarkable, and every traveller who visited Athens, was indebted to his hospitality, and could bear testimony to the amount of valuable information which a long residence in Greece had enabled him to acquire, respecting the antiquities of Greece.

The following donations were announced as having been received since the last Ordinary Meeting. Signor Campanari; Antichi vasi dipinti della collezione Feoli, descritti da Secondiano Campanari. Roma 8vo.—Sir John Drummond Stewart; various original drawings by P. Cortona, J. B. Corneille &c.; through C. Barry, Esq. V.P.—Thomas L. Walker, Esq.; "Examples of Gothic Architecture," part 3rd, folio; by the Donor.—B. Vulliamy, Esq.; an eight day clock, with oak case.—Royal Society; Transactions for the year 1837, parts 1 and 2, and various pamphlets.—Monsieur Blouet, Honorary and Corresponding Member; Rapport sur les Penetenciers des Estats-unis par MM. de Metz et Blouet. Paris, folio.—Henry Rhodes, Fellow; Twenty Pounds for the Travelling fund; print of Grinling Gibbons, and framed drawing of portrait of C. Le Brun.

Resolved that the cordial thanks of the Institute be presented to the Donors above named.

Mr. A. H. Renton continued his papers on iron; the forms of sections and their comparative value.

Mr. Holtzapffel explained the modes of using the scales invented by him.

ARCHITECTURAL SOCIETY.

Ordinary Meetings of the Society, held at their Rooms, 35, *Lincoln's Inn-fields.*

April 10.—The subjects announced for the production of sketches, were as follows. Members;—A design for an entrance to an Arsenal. Students;—A design for a Light-house at the end of a Pier; with a plan.

Mr. George Moore read a very interesting paper, entitled "A Review of the Architecture of the Middle Ages."

May 8.—Mr. François Kreiter, residing at Munich, was elected an Honorary and Corresponding Member.

Subjects for sketches. Members;—A design for a Villa in the Italian style. Students;—A design for a Chimney-piece in a drawing-room of a Nobleman's mansion.

Mr. James Barr read an interesting paper on the "Elementary principles of design in Architecture."

May 22.—Mr. T. L. Walker presented to the Society, a proof copy of the third series of the "Examples of Gothic Architecture."

The report from the Sketching Committee was presented; and the several productions offered by the Student Members in competition for the prizes, were exhibited this evening in the rooms. The prizes are to be awarded on the 1st of June; on which occasion the Society holds its last conversazione for the session.

The essays forwarded in competition for the prizes were this evening read; and in consequence, no further papers were read by the Members.

KING'S COLLEGE, LONDON.

Class of Civil Engineering and Mining.

We perceive with much satisfaction, that the Council of King's College, have followed the example of the Senate of the University of Durham, which in an early number of the Journal we noticed with approbation, by resolving to form a class of Civil Engineering and Mining. We have been obligingly furnished with some particulars of their plan. The course will occupy from two to three years, and will comprise the following important subjects;—Mathematics, Mechanics, Hydrostatics, and Hydrostatical Machines; the Steam Engine and its applications; theoretical and practical Chemistry; Metallurgy, Geology, and Mineralogy; the theory and practice of Mining; the elementary properties of Matter, Sound, Light, Heat, and Electricity; Machine-drawing, practical Perspective, and Surveying. These subjects will be treated, partly by the Professors of the College, partly by masters specially appointed. The courses will begin about the 1st of October, and close about the 1st of July in each year. Students will be admitted at fifteen years of age;—we wish it might be, fourteen; for in most cases, they will not be articled to Engineers till they have passed this course, that is till about eighteen;—and the expense of their education will consequently be much increased. It is intended to hold special examinations in this department, and grant certificates of honour to those who deserve them. And those who have gone through the whole course, obtaining these certificates, will be admitted into the class of "King's College Associates."

We wish the Council full success in their very laudable undertaking; and augur the best results to the rising race of Engineers who may take advantage of the opportunities thus offered to them. From English mechanical ability, cultivated to the utmost by scientific knowledge, and then farther exercised by practical experience, we anticipate advances in the mechanical arts which shall leave the future age no reason to be ashamed, when compared even with the present days of Railways and Steam Navigation.

SOCIETY FOR PROMOTING PRACTICAL DESIGN,

AND DIFFUSING A KNOWLEDGE AND LOVE OF THE ARTS AMONG THE PEOPLE.

St. Martin's Street, Pall Mall East.

The Schools of this Institution are now open; and instruction is at present given to nearly a hundred youths and mechanics. On account of the want of accommodation in the premises which they now occupy, the Society's rooms will be removed in June to Saville House, Leicester Square.

Lectures are delivered every Tuesday and Friday; and include in the present quarter, a course of twelve lectures on the Fine Arts, by B. R. Haydon, Esq. The course includes likewise lectures on Architecture, Pneumatics, and the Steam Engine. In a lecture on Architecture in England, on the 1st of May, Hyde Clarke, Esq. supported the claims of the Gothic to be received as a style of Art, on all the laws of composition; pointing out the artistical skill which was observed in maintaining the strength and unity of the composition, and the knowledge of grouping exhibited in the great works of that style.

MEETING OF SCIENTIFIC SOCIETIES.

Royal Institute of British Architects, Monday evenings, June 4 and 18, at eight o'clock.

Architectural Society, Tuesday evening, June 5, at eight o'clock.

At a late meeting of the Geological Society of Dublin, Mr. Mallett exhibited specimens of Irish minerals, some of them applicable to economic purposes, and explained their uses. The most important were—ochres from Howth and Lambay, fit for making pigments, of which eight specimens were exhibited; Fuller's earth, from Lambay; porcelain clay, from the Sutton side of Howth; sand, for moulding, from Belfast Lough, said to be superior to the English, and quite equal to the Scotch; a mass of conglomerate, cemented by arragonite, from Salthill, Kingstown; and a specimen of sulphuret of nickel from Sheffoy Hill, county of Mayo. It is the first time that this latter mineral has been discovered in Ireland.

PARLIAMENTARY PROCEEDINGS.

House of Commons.—List of Petitions for Private Bills, and progress therein.

Those marked thus — are either withdrawn or rejected.

	Petition presented	Bill read first time.	Bill read second time.	Bill read third time.	Royal Assent.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 28TH APRIL, AND THE 24TH MAY, 1838.

John Paterson Reid, Power-Loom Manufacturer; and Thomas Johnson, Mechanic, for "Certain Improvements in preparing Yarn or Thread, by Machinery suitably for Warps in preparation for Weaving in Looms."—28th April; 6 months.

Joseph Jepson Oddy Taylor, of Gracechurch Street, in the City of London, Machinist, for "An Improved Mode of Propelling Ships and other Vessels on Water."—1st May; 6 months.

Miles Berry, of Chancery Lane, in the County of Middlesex, Patent Agent, for "A New and Improved Method or Process of Alloying Metals by Cementation, particularly applicable to the Preservation of Copper, Wrought or Cast Iron, and other Metals, and thereby operating a change in the appearance of their Surface, and giving them more brilliancy. Communicated by a Foreigner residing abroad."—3rd May; 6 months.

John Ball, of Finsbury Circus, in the County of Middlesex, Merchant, for "Improvements in Carriages. Communicated by a Foreigner residing abroad."—3rd May; 6 months.

Edward Cobbold, of Long Melford, in the County of Somerset, Clerk, Master of Arts, for "Certain Improvements in the Manufacturing of Gas for affording Light and Heat, and in the Application of certain Products thereof to useful Purposes."—5th May; 6 months.

Edmund Shaw, of Fenchurch Street, in the City of London, Stationer, for "Improvements in the Manufacture of Paper and Paper Boards. Communicated by a Foreigner residing abroad."—5th May; 6 months.

Thomas Joyce, of Camberwell New Road, in the County of Surrey, Gardener, for "Certain Improved Modes of applying Prepared Fuel to the purposes of Generating Steam and Evaporating Fluids."—5th May; 6 months.

Pierre Armand Lecomte de Fontainemoreau, of Charles Street, City Road, in the County of Middlesex, for "An Improved Method of preventing the Oxydation of Metals. Communicated by a Foreigner residing abroad."—5th May; 6 months.

William Gossage, of Stoke Prior, in the County of Worcester, Manufacturing Chemist, for "Certain Improvements in Manufacturing Sulphuric Acid."—8th May; 6 months.

William Henry James, late of Birmingham, and now of London, Civil Engineer, for "Certain Improvements in Machines or Apparatus for Weighing Substances or Fluids, and for certain Additions thereto applicable to other Purposes."—8th May; 6 months.

William Crofts, of Radford, in the County of Nottingham, Machine Maker, for "Improvements in the Manufacture of Lace."—10th May; 6 months.

Miles Berry, of Chancery Lane, in the County of Middlesex, Patent Agent, for "A New or Improved Method of Applying certain Textile and Exotic Plants, or Substitutes in various Cases for Flax, Hemp, Cotton, and Silk. Communicated by a Foreigner residing abroad."—14th May; 6 months.

Jean François Isidore Caplin, of Portland Street, in the County of Middlesex, Artist, for "Improvements in Stays or Corsets, and other Parts of the Dress where Lacing is employed, and in Instruments for Measuring for Corsets or Stays, and for the Bodies of Dresses. Communicated by a Foreigner residing abroad."—14th May; 6 months.

Alexander Happey, of Basing Lane, in the City of London, Gentleman, for "A New and Improved Method of Extracting Tar and Bitumen, from all Matters which contain those Substances, or either of them. Communicated by a Foreigner residing abroad."—14th May; 6 months.

Thomas Mellodew, of Wallshaw Cottage, near Oldham, in the County of Lancaster, Mechanic, for "Certain Improvements in Looms for Weaving various Kinds of Cloth."—15th May; 6 months.

James Vincent Desgrand, of Size Lane, in the City of London, Merchant, for "A certain New Pulpy Product or Material, to be used in Manufacturing Paper and Pasteboard, Prepared from certain Substances not hitherto used for such Purposes. Communicated by a Foreigner residing abroad."—15th May; 6 months.

Francis Hope, of Knaresborough, in the County of York, Flax spinner, for "Certain Improvements in Machinery, or Apparatus for Heckling, Preparing, or Dressing Hemp, Flax, and other such like Fibrous Materials.—15th May; 6 months.

David Stead, of Great Winchester Street, in the City of London, Merchant, for "Making or Paving Public Streets and Highways, and Public and Private Roads, Courts, and Bridges with Timber, or Wooden Blocks. Communicated by a Foreigner residing abroad."—19th May; 4 months.

Samuel Seaward, of the Canal Iron Works, in the Parish of All Saints, Poplar, in the County of Middlesex, for "Certain Improvements in Steam Engines."—21st May; 6 months.

Augustus Applegath, of Crayford, in the County of Kent, Calico Printer, for "Improvements in Apparatus for Block Printing."—22nd May; 6 months.

Henry Adcock, of Liverpool, in the County of Lancaster, for "Improvements in Raising Water from Mines and other Deep Places, or from a Lower Level to a Higher; which Improvements are Applicable to Raising Liquids Generally, and to other Purposes."—22nd May; 6 months.

John Ratcliff, of Birmingham, in the County of Warwick, Lamp Manufacturer, for "Improvements in Lamps."—22nd May; 6 months.

Robert Martineau, of Birmingham; and Brook Smith, of the same place, Cock Founders, for "Improvements for Cocks, for Drawing off Liquids."—24th May; 6 months.

John Radcliffe, of Stockport, in the County of Chester, Machine Agent, for "A New Method of Removing the Fly, Droppings, Waste, and other Matters; which, being separated from the Material, falls below the Cylinders and beaters in the respective processes of Carding, Willowing, Devilling, Batting, Blowing, Scutching, Opening or Mixing of Cotton-Wool, Silk, Flax-Wool, or any other Fibrous Material or Substance."—24th May; 6 months.

Charles Searle, of Fitzroy Street, London, in the County of Middlesex, for "A New Description of Ærated Water or Waters, and which Method of Ærating is Applicable also to other Fluids."—24th May; 6 months.

STEAM NAVIGATION.

The "Sirius" and "Great Western" Steam ships.—Great has been the interest excited during the past month respecting the progress of the grand experiment which these vessels have been trying. And now that they have both returned, in safety and with honour, we think we cannot do better than give a brief summary of the scraps of news respecting them, which we have amused ourselves by collecting. Every vessel arriving from America, was eagerly questioned whether she had met the adventurers in whose fate the world was interested. The Sirius was the first heard of; and from her position as reported by one vessel after another, her rate of sailing was calculated. The Sirius had been repeatedly spoken with, before any tidings had been heard of the Great Western; and one paragraphist at least, ventured to express "much anxiety" respecting her. But the Atlantic is a tolerably large extent of water even for the Great Western to sail upon; and her proprietors, strong in faith, did not think fit to discontinue their advertisements that she would "leave Bristol for New York, on or about the 26th inst." And the Sirius in like manner was advertised as "intended to leave London on the 23rd inst., and Cork on the 28th inst.". The Great Western was discovered at last; and as if to make up for lost time, spoke with four ships in two days. And now was the time for calculation; it was found that the Sirius had not retained the start she had set off with; and bets were eagerly laid, especially at Bristol it is said, that the Great Western would reach New York the first. If any, like ourselves, have laid down upon the map the various situations given for the two vessels on successive days, comparing the different accounts, they may like us have met with interesting results. We did hear indeed of one journalist who took the liberty to place one of the ships one day in the centre of some continent or other, not generally supposed to lie in the way to New York;—perhaps she went for fuel. For ourselves, we have met with no such decided vagaries, and are inclined to think that neither of the vessels *bolted* in the race. The result of the outward voyages is as follows: the Sirius sailed April 4, arrived April 22 evening, was out 17 clear days from Cork; the Great Western sailed April 7, arrived April 23 morning, was out 15 clear days from Bristol. Their arrival appears to have created even a stronger sensation in New York, than their departure in England;—and not unnaturally,—the winning post is always a place of keener interest than the starting post; in this case also there were two starting posts, but only one goal. Of the homeward voyage, each ship of course brought her own first account; they might tell of sailing vessels passed and likely to arrive, but must be their own heralds to their native shore. The Sirius sailed May 1st, afternoon, arrived at Falmouth May 18th evening, was out 16 clear days. The Great Western sailed May 7th, arrived at Bristol May 22nd, was out 14 clear days. The Sirius returned to the Thames on Monday night the 21st ult., and was expected to leave for Cork on Saturday, and to sail thence on Wednesday the 30th; thus exceeding her advertised time but two days. Nor need the Great Western probably delay much beyond the advertised time for her second trip. On the whole, we consider the experiment triumphantly successful; and doubt not speedily to have to report an average time for the trans-Atlantic voyage. It will be seen, that the Great Western has the advantage of her rival in point of speed; as indeed was to be expected from her having been built expressly for this station. We do not expect again to report of her as we did last month, that several of her intended passengers forfeited their fare through fear of sharing in the risks of the experiment she was about to try. The experience of her homeward voyage was very different; she brought 68 cabin passengers, the greatest number it is said, that ever crossed the Atlantic in one ship. She will speedily have to cope with rivals, like herself built for Atlantic navigation;—nor need she fear; she has proved herself excellent, and if others surpass her, she will still retain her early honours, and keep up a reputation high at any rate, if not the highest.

The "British Queen."—This magnificent steam ship was launched, or, more properly speaking, floated out of dock, on Thursday, 24th ult. She is the property of the British and American Steam Navigation Company, and has been built by Messrs. Curling and Young, at their ship-yard in Limehouse: the engineering contract is being executed by Messrs. Napier and Co. She is destined to carry cargo and passengers between London and New York. Her launch from the stocks was found to be impracticable in consequence of the size of the dock and the depth of the water in front; she was therefore necessarily floated out.

Precisely at two o'clock, it being at that time high water, the signal was given, the stupendous vessel took leave of her moorings, and as she majestically ploughed her way into the river, amidst the rejoicings of the multitude, the Honourable Mrs. Dawson Damer, who occupied a conspicuous position upon a platform erected for the purpose, was seen to hurl at her the baptismal offering, and christen her the "British Queen." When she reached the river, being surrounded by vessels of the ordinary size, her huge proportions became even more apparent than they were before. Having floated a short distance up the river with the tide, she was taken in tow by the Fame steamer, and finally cast anchor outside a tier about a quarter of a mile below Messrs. Curling and Young's yard, where she lay till the next day, when she was taken into the East India Docks.

The period of her embarkation is not yet fixed; but the expectation is, that it will be about October or November next. She has not at present any of her internal fittings or decorations, but they will be proceeded with immediately.

Her state cabin or saloon is a noble apartment. What, we believe, is called her figure-head, is a graceful full-length of the Queen, with the sceptre in her right hand and the orb in her left. The likeness of her Majesty is excellent. The vessel's present draught of water is only ten feet; and when her engines are in and she is thoroughly equipped, her draught will be sixteen feet. The number of passengers for whom accommodation is to be provided is in the whole 280.

DIMENSIONS OF THE VESSEL AND ENGINES.

Length, extreme, from figure-head to taffrail	275	feet.
Length on upper deck	245	„
Length of keel	223	„
Breadth of beam	40½	„
Breadth, including paddle-boxes	64	„
Depth	27	„
Tonnage	1,862	tons.
Power of her two engines	500	horse.
Diameter of cylinders	77½	inches.
Length of stroke	7	feet.
Diameter of paddle wheels	30	„

Estimated weight of engines, boilers, and water -	500	tons.
Ditto of coals for 20 days' consumption - -	600	„
Ditto of cargo - - - - -	500	„
Draught of water with the above weight and stores -	18	feet.

The British Queen is believed to be the largest ship in the world, the length exceeding by about thirty-five feet, any ship in the British navy.

The New Quicksilver Steam ship "Columbus."—This splendid new steamer, destined shortly to cross the Atlantic, which has created much interest, from the novel construction of its machinery, on April 24th took a trial trip down the Mersey and round the light-ship, with a highly-respectable party of gentlemen on board. She excited much curiosity on the river, from the novelty of her appearance and the beauty of her model. The Columbus is 330 tons, builders' measurement, being 21½ feet beam, and 145 feet keel, with 18½ feet depth of hold. She has 2 engines equal to 110 horse power; the cylinders are 40½ inches diameter and 3½ feet stroke, and the wheels 17½ feet diameter. Her speed through the water is ten statute miles per hour; her immersed section at her present load is 150 square feet. She has now on board twenty days' fuel, besides 30 tons of iron ballast. The novelty of the engines (Mr. Howard's patent) consists in a new method of producing the steam, and of condensing it, the latter part of the invention being applicable to the ordinary boilers. In a boiler the heat from the fuel is passed over very extensive surfaces, in contact with which is a large body of water, the temperature of which is always such as is due to the density or pressure of the steam, and consequently the evaporation is limited by such circumstances. In this invention the steam is formed by bringing a small quantity of water previously made boiling hot, in contact with a comparatively small surface, heated to, and *maintained at* the temperature of most rapid vaporization, viz. about 400 deg., to effect which a quantity of mercury or amalgam lies between iron plates, the one near the fire being a plain surface of only three quarters of a foot per horse power, and the other, or vaporizing surface, being about four times as much. The steam never obtains a density or pressure due to the temperature, but is itself heated to about 400 deg., and worked at about ten pounds to the inch, and cut off from the cylinder at half the stroke. The condensation is effected by the repeated *injection* of the *same* water. This principle of condensation is effected as follows, on board the Columbus:—the air pumps withdraw the warm injection water from the condensers into the hot cisterns, from which it passes slowly through a series of copper pipes exposed to the action of the external cold sea water in a cistern supplied by a pump, on the air pump cross-head, and then is re-injected amidst the steam in the condensers, after having been effectually cooled by its transmission through the pipes. This process of condensation is obviously equally applicable to the ordinary engines with boilers, and is most effectual. The fuel made use of is coke or stone-coal, or fuel giving a strong local heat and little flame; that employed on Tuesday was Kilkenny coal. The consumption of fuel is three tons per day of 24 hours, and the fire grates have a total bar surface of only 22 feet, the air being supplied by a small blowing machine, under easy regulation. The iron plates exposed to the fire are perfectly secured from any bad effect from the somewhat intense heat, by the close contact of the mercury within them, which absorbs and gives out the heat with the utmost rapidity. The combined effect of the reduction in the consumption of fuel, and the weight and size of the vaporizers, compared with boilers, is such that a steam vessel of any ordinary tonnage and power will be enabled at her loaded immersion to make a voyage of *five times* the length now practicable.—*(Abridged from the Liverpool Standard.)*

India Steam Navigation Company.—We understand that Sir John Ross, R.N., the Chairman, and Mr. C. Manby, the Engineer of the Company, have been to Liverpool to endeavour to negociate for the purchase of a steam ship suitable for their service, but that they were unsuccessful. We do not think it likely that they will meet with one that will suit their purpose, and they had much better go to work boldly, and give directions for the building of a vessel and the construction of engines immediately. The successful trips of the Sirius and the Great Western across the Atlantic have mainly set the question at rest as to the practicability of a voyage by the Cape to India.

New Iron Steam Packet.—On Wednesday, the 9th ult., the launch of another iron steam boat from the manufactory of Messrs. Fairbairne and Co., Millwall Works, Poplar, took place. Notwithstanding the rapid advance which this description of vessels has of late years made in public estimation, the port of London has been, if we may so term it, second in the race,—comparatively few having been launched upon the Thames. This may in some degree account for the interest which the launch excited. The ceremony of naming the vessel, which has been called the Nevka, was performed by Miss Fairbairne; and at half-past one, the last of the shores having been knocked away, the boat glided gently and gracefully into the water, amidst the waving of flags and the hearty cheers of the thousands of spectators who lined the shores or were stationed in boats around. The Nevka has been built for the Emperor of Russia's private use, and measures 148 feet in length, by 18 feet in beam. She is of nearly a similar model with the Sirius, launched from this factory a short time since, and combines great stowage-room, in proportion to her bulk, with a strength and buoyancy hitherto unattainable in boats built with timber. Her draught of water when afloat was only two feet three inches, and with her boilers and all her *materiel* aboard she will draw little more than three feet. The builders have received *carte blanche* for the fittings up and decorations, which will be of the most costly and elegant description.

Steam Communication with Yarmouth.—A splendid new steam-packet, named the Circassian, Mr. James Hardie, commander, has recently commenced running between London and Yarmouth. She is the property of the Clyde Steam Navigation Company, and was built by Mr. Charles Wood, at Dumbarton. As a specimen of nautical architecture, she is in strict keeping with other productions from the romantic and far-famed banks of the Clyde. She is 400 tons burthen, propelled by engines of 150 horse power, and is said to be capable of accomplishing the passage between London and Yarmouth in twelve hours.

Poole, May 4.—On Thursday last, the Commercial Steam Company's steamer Cornubia arrived here. On Thursday a public meeting of the inhabitants was held at the Guildhall, for the purpose of taking into consideration a proposal from the Commercial Steam Packet Company, for placing a steamer between Poole, the Isle of Wight, Southampton, Portsmouth, and London. Mr. G. Penney being called to the chair, several resolutions were unanimously entered into for carrying the same into effect, the company offering to establish a packet here, on the inhabitants taking 400 shares of 5*l.* each, which no doubt will soon be done. The Cornubia will start for Southampton on Monday next.

Quick Sailing.—A new steam-ship, of 560 tons, built by Mr. George Mills, Bowling Bay, started from Greenock on Friday night, April 27, at 12 o'clock, for London (by the South of England), and arrived at 12 o'clock forenoon, on the following Tuesday, having performed the passage in the short space of three days and twelve hours, including four hours stoppage for a pilot at Dungeness.—*Glasgow Herald.*

PROGRESS OF RAILWAYS.

London and Birmingham and Grand Junction Railways.—We have heard with much pleasure that there is no longer any foundation for the opinion, that any misunderstanding exists between the directors of these two companies. On the contrary, we are assured that the mode to be adopted at Birmingham, when the lines are each finished there, for the transfer of the passengers and their luggage from the one line to the other, has been satisfactorily arranged; but that until the permanent station of the Grand Junction Company, contiguous to that of the London and Birmingham Company in Curzon-street, has been completed, the inconvenience of going from one station to the other, in omnibuses, as at present, is unavoidable. We understand also, that the directors of the London and Birmingham line are at present much restricted in their power of changing the hours of departure and arrival of their trains, on account of engineering operations still in progress on those parts of the line which have been recently opened; and from some difficulties connected with the horsing of the coaches on the road, between Denbigh Hall and Rugby, a work in which, we believe, no fewer than 700 horses are already engaged. It is their intention, however, as soon as these difficulties are removed, to curtail any unnecessary detention in Birmingham; and it is proper to add, that as the directors of this company have made all their arrangements with a view of insuring the most perfect punctuality in the arrival of the trains, as well at the intermediate stations, as at the two termini, the most prompt measures have been taken to remove every cause of detention, which the first few days of working the line brought to light; and it may reasonably be expected, that in a very short time the travelling upon it will be attended with as few inconveniences as are compatible with a partial opening. We believe we may add, that it is intended to set on one or two additional trains immediately, with an especial reference to the convenience of travellers from Manchester and Liverpool.—*Manchester Guardian.*

Gloucester and Birmingham Railway.—The contractors of the Balsall Heath line of road are staking out the ground, and have commenced removing the soil from the hill on the side of Moseley, for the purpose of embankment towards Camphill; which will in some places be about nine yards above the present elevation of the land. An inquisition was held on April 28th, at the Orange-tree Tavern, Highgate, Birmingham, for the purpose of ascertaining the amount to be paid by this company to James Taylor, Esq., of Moseley, as a compensation for his interest in some gardens, called the "Guinea Gardens," lying about a mile from Birmingham. The quantity of land required, was 2a. 3r. 15p., for which 1,278*l.* 6s. 8d. was asked by Mr. Taylor; 600*l.* was offered by the company, and 910*l.* adjudged by the jury.—*Gloucestershire Chronicle.*

Hull and Selby Railway.—Upwards of 25,000*l.* has been received out of 40,000*l.*, the amount of the third call of 5*l.* per share, due on the 16th ult. A great number of men are employed on various portions of the line; and Mr. Walker, the chief engineer, who was in Hull last week, and went over the works, has expressed his satisfaction with the manner in which they have been thus far executed, and with the progress made.—*Hull Observer.*

Eastern Counties Railway.—The works of this railway, between Mile-end and Romford, are now prosecuting with great activity. The temporary terminus will be at a large open space on the right side of Dog-row, within less than a furlong of Mile-end turnpike, the great eastern outlet of the metropolis. The embankments which are to connect the bridges and culverts over the numerous tide-streams that intersect the Stratford marshes, are under contract to be finished before the middle of May. The stuff for the purpose (gravel of the finest quality) is supplied from a cutting from 8 to 14 feet deep, which commences close to Angel lane, at the back of Stratford, and is continued by Maryland Point, Forest Gate, and Holmfirth House, to the valleys of the Aldersbrook and Roding. The bridge over the Aldersbrook is done, all but the parapets; and that over the Roding is up to the springing of the arches. Between these two bridges there is an embankment about 20 feet high, more than two-thirds of which are completed. Another short embankment of about 18 feet high, which is also nearly finished, carries the railway from the Roding bridge to a level at the entrance of the town of Ilford, immediately behind the Red Lion Inn. Here there will be a station, and a broad entrance from the turnpike road. Before the railway leaves Ilford, it descends again into a cutting, which extends in a north-easterly direction to the valley of the Rom, passing under the turnpike road at the eight-mile stone. At this point a very considerable deviation from the turnpike road has been found requisite, and has been executed. In a few days it will be in a state of consolidation fit for the reception of the traffic of the road; and then the bridge, which is to carry the old road over the railway will be begun. The officers of the company still speak with confidence of being able to open to Ilford in July or August.—*Railway Times.*

Sheffield, Ashton-under-Lyne, and Manchester Railway.—The meeting of directors, at Penistone, on April 18th, was the most important which has been held since the passing of the act. Mr. Vignoles received his final instructions to commence immediately, on various parts of the line, so as to stake out and accurately determine the land required to be purchased, by the end of this year, or the beginning of next; also to complete the drawing of plans, sections, &c., preparatory to letting the contracts.—*Sheffield Independent.*

Glasgow and Ayrshire Railway.—We are glad to observe that this undertaking is now on the eve of being commenced—contractors being invited to come forward to execute the works extending from Ayr to Irvine. The operations at the other extremity are also in progress; and we understand that the contracts are concluded for the portion between Irvine and Kilwinning, including two spacious bridges over the Irvine and Garnock rivers.—*Glasgow Chronicle.*

Glasgow, Paisley, Kilmarnock, and Ayr Railway.—We understand, that the works on the portion of the Railway in Ayrshire have been commenced, and that the foundation-stones have been laid of the important bridges over the Garnock and Irvine waters. Tenders have likewise been received for forming the line between Irvine and Ayr; and these, as well the contracts between Irvine and Dalry, are at a rate below the engineering estimates. The line from Dalry to Ayr is expected to be

opened at the end of next summer, and that between Glasgow and Johnstone a few months later.—*Glasgow Courier.*

Bristol and Exeter Railway.—The works in this line are proceeding most vigorously, and we perceive that three further contracts are advertised, extending from Lympsham to Bridgwater, a distance of about twelve miles, and completing the thirty-three miles which are to be opened in the course of next year. This line, though of less than half the cost per mile, owing to its naturally easy levels, is being constructed on the same principles as the "Great Western."

Commercial Blackwall Railway.—This company is purchasing the property on the line as fast as it can; and the instant possession shall have been obtained, operations will be commenced.

Railway from Northampton to the London and Birmingham Line.—This branch Railway is in contemplation, and a survey has just been completed by an engineer, whose report is very favourable.

Taff Vale Railway.—This Railway is progressing very favourably. Satisfactory arrangements have been made with nearly the whole of the proprietors whose lands will be wanted, and along the whole line the utmost activity is now perceptible. The portion comprised in the Cardiff district was commenced last week, and already conveys an idea of its formation when ready. It is avowed by those most competent to give an opinion, that in less than eighteen months the Railway will be opened as far as Quaker's Yard from Cardiff. The Bute Ship Canal will also be completed about the same time; and, these two stupendous undertakings combined, must soon contribute to place Cardiff much higher in the scale of maritime towns than it stands at present.—*Cambrian.*

North Union Railway.—The contractors for this line have availed themselves of the late favourable weather for carrying forward the operations, now fast progressing towards completion. The bridge across the Ribble will be the only impediment to finishing the undertaking by August, as originally contracted for. At the Wigan end, the embankment has already been extended to a considerable distance over the iron bridge in Wallgate, in that town; and, if the weather continue fine, and the same number of men constantly employed as there has been for a considerable time back, a very short period will elapse ere the North Union Railway will be joined to the line which leads from Parkside to Wigan.

Cheltenham and Great Western Union Railway.—From the half-yearly report of this company, presented on the 4th ult., we make the following extract:—"The directors have great satisfaction in being enabled to report that the bill introduced in the present session of parliament has been read a second time in the House of Lords—that the evidence on it has been taken in the committee, and that it only waits the arrangement of some new clauses, which the Lords require to be introduced into all future railway bills, prior to the third reading. This bill is one of very great importance to the company. It empowers them to make the deviation applied for, in the tunnel at Sapperton, which will considerably diminish its length and expense, and will obviate the objection formerly so much urged against it, that it was curved, by rendering it straight. In order to effect this, however, that portion of the line must be commenced without delay, and the works must be carried on simultaneously with that portion of the railway lying between Cirencester and Swindon. This necessarily deranges, to some extent, the plan of operations resolved on at the last general meeting; but as there can be no doubt of a profitable return for the outlay, and as it is of the greatest consequence to this company to retain all their existing rights, without the interference of another company on any portion of their line, the directors have no hesitation in recommending that all necessary measures be immediately adopted to secure the construction of the line from Cheltenham to Gloucester, by the time appointed. The directors are enabled to state, from authority, that the Great Western Railway will be opened to Maidenhead early in June. They are gratified in being enabled to state that public confidence in the superiority of the mode of construction of that railway, adopted by Mr. Brunel, over that of the lines now in use, is daily increasing; that they feel convinced the result will be eminently successful, and that they entertain no doubt but the opening of that line will have a very beneficial influence on the interests of this company, so intimately connected with it."

Midland Counties Railway.—This company offered Mr. Needham 1,500*l.* for the land required by them, a few hours before the inquiry took place. Mr. N. claimed 2,800*l.* 10s. The jury awarded him 1,260*l.*—loss by going to a jury, 240*l.*

Northern and Eastern Railway.—On Tuesday, the 15th ult., a special general meeting of the shareholders of this company took place at the City of London Tavern, Bishopsgate-street, H. G. Ward, Esq., M.P., in the Chair,—to deliberate upon a plan now in contemplation, to effect a junction between the Northern and Eastern, and Blackwall Commercial Railways, by means of a branch line passing from Tottenham Mills on the Northern and Eastern, to the terminus of the other line at Blackwall. The terminus of the Northern and Eastern line, as originally proposed, was Islington; and one of the advantages that would result from the adoption of the junction line, would be the getting rid of an immense outlay in constructing the portion of the railway from Tottenham Mills to Islington, which is the most difficult and costly part of the undertaking, and the only part where tunnelling is required. The chairman having explained the object for which the meeting had been convened, reports were read from the directors of the company, and from Messrs. George Stephenson and George Bidder, the engineers of the Blackwall Railway, detailing the advantages which would result from the project; such as securing a direct communication with the river, and with the heart of the city. The plan proposed for carrying the junction line into effect was stated to be by means of a new company, consisting of the shareholders of the existing companies and others, and it was thought that an act of incorporation could be obtained next session. The total cost of the junction line would be about 120,000*l.* Several gentlemen addressed the meeting, and expatiated on the advantages that would result from the scheme. Mr. Routh, chairman of the Blackwall Company, expressed his cordial concurrence, and that of his co-directors, in the plan. Resolutions, authorising the directors to carry the scheme into effect, subject to the confirmation of a subsequent meeting, were carried unanimously.

Caledonian, Furness, and West Cumberland Railway.—It is not generally known that Mr. Hague, now engaged in the survey of this line, is the inventor of the patent pneumatic machinery, by which the transfer of power may be accomplished with little friction for many miles; and the powerful streams of water in the north, rendered available, to the extension of its manufactures and the increase of its mining produce.

London and Birmingham Railway.—On Thursday the 24th ult., the workmen completed the removal of the immense scaffolding, fronting the stone entrance to the London station at Euston Grove. During the week the elegant iron gates will be affixed, and the wooden palings removed. The whole, when completed, will present an elegant appearance from Euston Square and the New Road.

Birkenhead Railway.—There is now an immediate prospect of the Chester and Birkenhead railway being commenced. The contractors have broken ground, and the company's agent has certified before John Dean Clare, Esq., a county Magistrate, that the whole of the money is subscribed. The Sheriff summoned a jury, to meet at Birkenhead, on Thursday last, to assess the value to be paid for the land to be taken from those gentlemen who art not satisfied with the valuation put on it by the company's surveyor.

Newcastle and Carlisle Railway.—On Wednesday the 3rd ult., a meeting of the directors was held at Haltwhistle, when it was determined to open the whole line (should no unforeseen event prevent it) on the 18th of June, the anniversary of the Battle of Waterloo.

Opening of the London and Southampton Railway.—On Tuesday, the 1st ult., the directors of this railway proceeded along the line from London to Woking-common, a distance of 23 miles, preparatory to its being opened to the public on the 14th. The object of the journey was to arrange the stations, as well as to test the safety of the line, and to give such orders as should insure the public against accidents on the opening. The excursion was most satisfactory. The engine employed on the occasion was made by Messrs. C. Tayleur and Co., of Warrington, and during some parts of the journey, went at the rate of 25 miles an hour. It was a singular and gratifying circumstance that the directors were on this occasion accompanied by John Moss, Esq., the chairman of the directors of the Grand Junction Railway, and by Charles Lawrence, Esq., the chairman of the directors of the Liverpool and Manchester Railway; and these gentlemen both expressed themselves highly pleased with the state of the works, and comparatively finished state of the railway. On Saturday, the 12th ult., the directors, accompanied by a few personal friends, by the engineer, and many persons of distinction, set out from the terminus at Nine Elms, shortly before two o'clock, and accomplished the twenty-three miles and a half with perfect ease in forty-five minutes. Having partaken of a liberal luncheon, which had been provided for the occasion, the party again entered the carriages, and returned to town even with greater rapidity than they left it, for the distance home was accomplished in forty-three minutes. Nothing can exceed the ease and luxury of this mode of travelling—the carriages, elegant in outward appearance, are perfect models of comfort within—there is not a jar or shake of any kind to disturb even the most delicate nerves—the pace is as smooth as it is rapid. It is needless to observe, that the country through which the railway passes presents many of the choicest beauties of English landscape. On Monday, the 21st ult., the railway was opened to the public; and it is now in active operation, with omnibuses plying from various coach-offices in town, to its station at Nine Elms.

Great Western Railway.—The directors have advertised their intention of opening this line as far as Maidenhead on Monday, the 4th inst., for passengers only. There will be eight trains each way, daily; and, on the 11th, their arrangements will be complete for the conveyance of horses and carriages: and of passengers and parcels to be booked to various parts of the West of England, by coaches in connexion with the railway.

The Brighton Railroad.—The first brick of this important undertaking was lately laid on Clayton summit, by Mr. Creasy. The building is a tower, or observatory, for the purpose of overseeing the line; there will be one also at Balcombe, and a third on the Merstham summit, taking in the whole. These towers have each a tower within them, in which is an apparatus that secures the direction of the tunnels, and during the progress of the work, the whole line is under the observation of the three resident engineers. We perceive that the following three contracts have been advertised:—Croydon, Coulsdon, and Merstham.

Sheffield and Rotherham Railway.—The works on this line are proceeding with great rapidity, and to the entire satisfaction of the directors. A good portion of the permanent rails are already laid, and it is expected the railway will be finished in August next. The five-arched viaduct at Blackburn Brook is now completed, and is the largest piece of masonry on the line, as well as a substantial and neat building. Workmen are erecting bridges over the canal belonging to the river Dun company, and over the river Don. The former will be a stone bridge, and is expected to be the handsomest on the line. The latter will be a timber bridge.—*Sheffield Iris.*

Speed on Railways.—The extreme rapidity of railway travelling was, perhaps never so strikingly exemplified as on Saturday, the 12th ult., on the London and Southampton line. An engine was appointed to follow the train which conveyed the directors and their friends, and in going, as it went almost immediately after the train, of course it could not go faster than the train; but in returning, it was found that this engine would not be wanted, and it remained at the end of the line, as far as it is at present opened, two hours after the carriages with the directors, &c., had started. This engine then proceeded to London, and it accomplished the entire distance of twenty-three miles in no longer a time than twenty-five minutes, stopping once by the way to take up a passenger, so that it may be said to have travelled at the rate of very nearly sixty miles per hour.

Railroads v. Canals.—The proprietors of the Grand Junction Railway have made offers to the manufacturers and others to carry goods between Birmingham and Liverpool, at 1s. 6d. a cwt., being exactly the sum charged by the canal, the trade of which must be superseded if the tonnage dues are not immediately lowered.—*Worcester Journal.*

IRISH RAILWAYS.

List of Railways proposed to be made in Ireland.

Ulster Railway, Belfast to Armagh,	Engineers	William Bald, F.R.S.E. M.R.I.A. &c. and Thomas Woodhouse, Esq.
Dublin to Armagh - - -	"	William Bald F.R.S.E. &c.
Dublin to Mullingar - -	"	Charles Vignoles M.R.I.A &c.
*Dublin to Kilkenny - - -	"	John M'Niel and David Aher
Dublin to Limerick - - -	"	William Bald F.R.S.E. &c
†Cork to Cove - - - -	"	Charles Vignoles M.R.I.A.
Belfast to Hollywood - - -	"	William Bald F.R.S.E.
Cave Hill to Belfast - - -	"	Ditto
†Dundalk to Cavan - - -	"	John M'Niel M.R.I.A. &c.
Dublin to Galway - - -	"	William Bald F.R.S.E, and David Henry Esq.
†Dublin to Drogheda - - -	"	William Cubitt F.R.S. M.R.I.A. &c.

The only Railway now in course of execution in Ireland is the Ulster Railway, from Armagh to Belfast.

* Act obtained for 17 miles. † Act of parliament obtained.

ENGINEERING WORKS.

Dublin Harbour.—Hyde Clarke, Esq., C.E., has caused a minute and extensive survey to be made under the sanction of some of the local authorities, for the purpose of effecting an important improvement in deepening the entrance to Dublin Harbour, by cutting through the Isthmus of Howth Head, and thus admitting the tidal current to sweep away the North Bull Sand.

Berwick Harbour.—We mentioned some months ago, that the Berwick Harbour Commissioners, among other improvements which they contemplated for the harbour, had determined to procure a dredging machine for deepening the river. Mr. Gowan, shipbuilder, is at present constructing a barge for the purpose, and it is expected she will be off the stocks in the course of a month or so. The machinery is being manufactured at Leeds. A machine of this kind has long been wanted to render our harbour what it ought to be. We can now, however, look forward to its being made equal to any harbour on the coast.—*Berwick and Kelso Warder.*

Granton Pier.—On Friday the 4th ult. a model of this important work was exhibited to a number of gentlemen assembled on the pier. It will surpass in magnitude and accommodation every notion formed of it by those who have not studied the details; it is to extend 1,700 feet into the sea, that is about 500 feet in addition to its present length; a weather wall in the centre will run the whole length, dividing a broad carriage way on either side, intersected by two openings; near the landward and seaward extremities on both sides will be projected open frame work, through which several flights of steps will lead to the different landing elevations; above will be elegant sheds and powerful cranes, to plumb the hold, so that a full cargo of a London steamer will be unshipped in the small space of four hours. From the bottom of the seaward framework to the top of the landward framework will be an inclined causeway, bound with heavy freestone to the east and west of the level carriage way already referred to. In every respect the one side will be a reverse of the other. At ebb time there will be fourteen feet of water. The new road is spacious and the inclination easy. The whole work is proceeding rapidly, and it is expected that passengers will embark from it to the coronation ceremony.—*Caledonian Mercury.*

Opening of the Edinburgh Chain Pier Railroad.—We witnessed a very novel and a very delightful spectacle yesterday afternoon, on the arrival of the "Modern Athens" steamer, at the chain pier, from Dundee. This vessel, and her splendid and powerful coadjutor, have been again and again offered goods, but heretofore the chain pier was scarcely in a condition to receive them, the expense being so great in conveying heavy goods along it. But in order to meet the wishes of the public, the proprietors of the chain pier have erected a railroad upon it, with four or five four-wheeled trucks; and these carriages were in full operation for the first time yesterday. There was fully half a ton or more on each of the trucks, and we do not exaggerate when we aver, that a youth of fourteen years of age could have drawn this with ease. We understand that one of the great objects of this railway is to give facility to passengers' luggage, as well as to articles of merchandise.—*Caledonian Mercury, May* 10.

Weymouth Harbour.—An addition to the present pier-head from the Nothe Point, of 100 yards in length, is to be proceeded with immediately. The contract is up to low-water mark, to be executed by the 1st of November, 1838; this will form an outer harbour, and no doubt be the prelude to other material improvements at this port.

Aberdeen Harbour Improvements.—Mr. Walker's plan and report have been unanimously approved of by our harbour trustees, and steps have already been taken to proceed with the preliminary departments. The expense is estimated at 85,000*l.*, but the prosperous state of our harbour funds, and the growing increase of our maritime commerce fully warrant the expenditure. When the improvements are completed, Aberdeen will have the proud distinction of affording perhaps the safest and most convenient accommodation to shipping which can be found in Scotland.—*Aberdeen Herald.*

Projected Water-works at Carlisle.—A public meeting was lately held in the Town Hall, in that city, Peter Dixon, Esq., Mayor in the chair, for the purpose of adopting measures to obtain a survey of the town, with a view to the establishment of water works and sewers. The meeting, though not very numerous, was highly respectable, and the resolutions were carried unanimously.

NEW CHURCHES.

Opening of the Wellington Chapel, St. James's Park.—On Sunday morning, the 6th ult., the splendid building lately erected in the barrack-yard of the Wellington Barracks, St. James's-park, as a chapel for the regiment that may be stationed there, was opened for the performance of divine service.

New Church at St. John's-in-the-Wilderness, Leeds.—On Monday afternoon, April 30, the foundation stone of the new church to be erected at St. John's-in-the-Wilderness, was laid by the Venerable Archdeacon Musgrave, D.D. The ceremony took place at three o'clock, amidst a large concourse of spectators. There was also a numerous assemblage of freemasons, &c., who walked in procession. The architect of the intended edifice is Mr. James Child, of Eastwood, who has also obtained the prize for the best design of the intended Odd Fellows' Hall, in Leeds, of which he is in consequence appointed architect.

Handsworth.—The foundation stone for a new church at Handsworth, near Birmingham, was laid with the usual ceremonies on Tuesday, April 24th. The architect is Mr. Ebbels of Wolverhampton, who proved to be the successful candidate in a competition. The chapel is to be a neat Gothic building, with a tower and crocketted pinnacles, of the style of about the thirteenth century; and its dimensions in the interior 66 feet 6 inches long, by 40 feet wide. It is calculated to afford accommodation for about 926 sittings, including those appropriated to the use of the Sunday School children; of these 926 sittings, 518 will be free for the use and accommodation of the poor. The estimated cost of the erection is 3,000l., of which sum 1,400l. has already been received in voluntary subscriptions. Two sums of 500l. each are expected; one from the Diocesan Church Building Society, and the other from the Incorporated Church Building Society.

Chepstow, Monmouthshire.—The contracts for the new church are taken by Messrs. Price and Roberts of Chepstow. The Architect is Mr. Harris of Bristol. The building will be erected in the early Norman style, to agree with the present Old Church. The cost, including Architect's commission, and Clerk of Works, will amount to 3,000l.

New Churches in the Metropolis.—A new church is about to be erected in Lambeth. To meet the increasing wants of the population of that large parish three new churches in the Gothic style are nearly completed in Stepney parish, and one of the new churches to be erected in Rotherhithe is in a very forward state. The new church in New-street-square, parish of St. Bride, London, will be soon opened. The building of one for the parish of St. James, Westminster, has already commenced, and the first stone of a new church on Blackheath will shortly be laid. Two new churches will shortly be erected in the parish of St. George, Southwark, and St. George's-in-the-East.

Kirmington.—A spire added to the rural church in the pleasant vale and wealthy village of Kirmington, is nearly completed;—another proof of the intention of the Earl of Yarborough to beautify his extensive and improving estates in and about Brocklesby.—*Lincoln Mercury.*

Episcopal Residence at Ripon, Yorkshire.—This building is to be immediately commenced, under the sanction of the Ecclesiastical Commissioners. The architect is W. Railton, Esq., Tenders have been advertised for, which must be delivered on or before the 25th of June.

Bristol.—The Independent Chapel at Clifton, erected by Lady Hope in 1750, has been rebuilt on an enlarged plan. The new Chapel, with the addition of galleries all round, will seat 1250. The cost, including a new Organ, and Architect's commission, will amount to 2,500l. Mr. Harris of Bristol is the Architect. The chapel is heated by Messrs. Price and Manby's apparatus, which has given general satisfaction.

PUBLIC BUILDINGS AND IMPROVEMENTS.

The Manchester and Salford Bank.—This building occupies a plot of ground on the north side of Mosley Street, at the corner of Marble Street, the front part only being devoted to the purposes of the bank, and the back occupied by a substantial and excellent warehouse. The principal façade presents a frontage to Mosley Street of about thirty-nine feet, and consists of a rusticated basement, of a somewhat massive character, upon which are placed four very beautiful attached fluted Corinthian columns, three feet in diameter, supporting an entablature, surmounted by a pediment. The proportions of the classic model (that of the Temple of Jupiter Stator at Rome) have been very strictly adhered to; the carving of the foliage of the capitals and other parts, has been very beautifully executed; and, although the greater part of the elaborate enrichments of the original have been necessarily omitted, sufficient have been retained to render the effect at once chaste and elegant. The door and windows at the basement have plain arched heads, and the two ranges of windows between the columns are finished with neat and appropriate dressings; those to the first floor have also balconies resting on the plat band, upon which the columns are placed. The public room of the bank is wainscotted throughout with Dantzic oak, the four sides being divided into compartments by pilasters, supporting an entablature extending round the room; which latter is enriched with bronzed consoles, pateræ, and lions' heads. The natural beauty of the wood has been left to supply the place of number and richness in the mouldings, being only here and there slightly relieved with an inlaying of bronzed metal. This room has an enriched coffered ceiling, which has a light and elegant appearance, contrasted with the massive character of the walls; and altogether the effect is such as is peculiarly appropriate to a room used for this purpose. The cash-counter, desks, and fittings, are also of oak, with Spanish mahogany tops; the former inlaid with bronzed metal, and the whole are arranged with every regard to convenience and utility. All the external doors and windows of the bank, on the ground-floor, are secured by the revolving iron shutters, now coming into use (patented by Bunnett and Corpe, of London); the latter, as well as the lower range between the columns, are glazed with large plates of glass, giving a dignity to the building unattainable by other means. The directors' private entrance is in Marble Street, whence a stone staircase leads to the principal story, on which is the board-room, lighted by two large windows in the Mosley Street front. This room is finished very plain, and with few mouldings, it being intended eventually to decorate it in the style now so generally in use on the continent, and which is a revival of a common practice of the ancients, as exemplified in the splendid remains of Egypt and Greece, and more particularly in the domestic edifices of Herculaneum and Pompeii; and has been treated of in the "Transactions of the Institute of British Architects," and several recent German and French publications, as the polychrony of architecture. The remainder of this floor, and the entire of the next, are occupied with apartments appropriated to the domestic purposes of the establishment; and on the upper story, the warehouse extends over the whole site of the building. The whole has been executed from the designs, and under the superintendence of R. Tattersall, Esq., of Manchester; the masonry work by Messrs. Ibberson and Co.; and the remainder of the works by Messrs. Haywood and Courtis.—*Manchester Courier.*

Helstone, Cornwall.—The new Shambles and general Market House, is intended to be opened early in the present month. The fittings of the Shambles are of cast iron, and the timbers of the roof are exposed. The cost, including Architect's commission, and Clerk of Works, will be £3,000. A new Guildhall and Corn Market is also just commenced in the same town, on the site of the old market. The contracts are taken at 2,200*l.* Both of the above buildings will be constructed of Constantine granite. The Architect of both is Mr. Harris of Bristol.

Penzance, Cornwall.—The new Guildhall and Market-house erecting by Mr. Harris of Bristol, is expected to be finished in September next. It is an imposing building, having a large dome and cupola in the centre, which is 105 feet from the level of the street The front of the Guildhall is composed of a basement and Ionic portico, with a flight of steps ten feet wide on either side. It is built of granite obtained in the neighbourhood.

FOREIGN INTELLIGENCE.

French Railroads;—the Government and the Companies.—Paris, April 30.—The railroad question is, notwithstanding the report of M. Arago, likely to end in a compromise. The greater portion will be left to the operation of public companies, and the government will be allowed to do just enough to save their credit and keep up their control. In the mean time, however, every thing stands still. But for the opposition of the government, prompted by the administration of the *Ponts et Chaussees*, from false pride, or still more unworthy motives, the railway between Paris and Havre, for which all the funds were provided three years ago, would by this time

have been half completed, and that between [illegible] commenced—whereas another year must probably elapse before the law for either the one or the other can be passed. M. Adam, the mayor and banker of Boulogne, is now in Paris, endeavouring to forward the latter project, and has himself offered to furnish 40 millions of francs towards its execution. Of this sum M. Adam takes a very large portion from his own property; the remainder he has had no difficulty in finding, chiefly in the neighbourhood of Boulogne.

The debate on the railroads commenced in the Chamber of Deputies on Monday, the 7th ult., in a contest between the Minister of Commerce, who gives up the Rouen and Orleans lines to private companies, and the parliamentary commission, which insists on giving the execution of all the lines to companies. The minister says that a road like that to the Belgian frontier, requiring three millions and a quarter sterling ought not to be entrusted to companies in France, where undertakings of the kind are in their infancy, and where the amount would not be subscribed. The partisans of companies reply, that one half of the sum requisite for the Belgian railroad is already subscribed, which is all the guarantee required by the commission. They moreover retort on the minister that there is no excess of revenue, no fund at the government disposal for the execution of the road, except raised by extraordinary and onerous means. M. Duvergier d'Hauranne it was who put forth these arguments. He said that fifty-four millions of francs were voted in 1837 for public works, and one hundred and thirteen millions in the present year for canals and works, in all amounting to three hundred millions. There was another hundred millions required for old works to be completed, making four hundred millions; and to these the minister added the demand of nine hundred millions, even supposing that the 1,100 leagues of railroads be reduced to 600. To meet this enormous expenditure, the minister counted on the surplus of the revenue, the revenue of the sinking fund, and the profits of the railroads. But excess of revenue over expenditure there never was; and were such possible, France has a magnificent possession in Africa, capable of swallowing up one hundred times any such surplus. As to the reserve of the sinking fund, that would be employed in paying the holders of the Five per Cents., whilst to count on the profits of railroads was looking far on for profit. Such were the powerful arguments put forth by M. Duvergier d'Hauranne, against government undertaking the execution of railroads. Count Mole said that the great object of the government was so to steer with respect to this question, that the country should have the great lines of railroad of which it stood in need as early as possible. He said he had no confidence in a company for the execution of a great line of eighty leagues of railroad, no one being at present well assured of either the cost or profit of such an enterprise: government alone could do it. He insisted, therefore, on the great Belgian line being left to the government, as well as that from Avignon to Marseilles, which no company offered to undertake. He would cede to private companies the lines from the capital towards Havre and Bordeaux.

On Saturday the 19th ult., the Minister of Commerce presented six projects of law conceding the following railroads:—

1. From Montpelier to Nismes. 2. From Lisle to Dunkirk. 3. From Mezieres to Sedan. 4. From Bordeaux to Langon. 5 and 6. From certain mines to the Allier. The line from Montpelier to Nismes is important, Nismes being already connected or about to be connected by a railroad with the Rhone, and with the coal mines of Alais; and Montpelier being joined by another railroad to Cette, and to the great Canal du Midi. The road from Lisle to Dunkirk traverses the richest and most populous department of France, and unites its port, the fifth in importance, with Lisle. The road from Langon to Bordeaux is lateral to the Garonne, and is the road from the latter town to Bayonne, as well as to Toulouse. On Tuesday will be presented the road to Rouen and Orleans, as well as that from Calais and Boulogne to Amiens.

Continental Railways.—The Brussels journals state that seven Englishmen, who have been employed as constructors of engines and conductors on the several railroads of Belgium from their first commencement, have embarked at Antwerp for London, whence they will go into Russia, being engaged there in similar employments on very advantageous terms.

Railroad in Italy.—The project for an iron railroad between Leghorn and Florence has been sanctioned by the government, to which the various plans are to be submitted.

Belgium.—We understand that as soon as the railroad from Ghent to Ostend is finished, there will be a daily post established between England and Belgium, through Ostend, the packets sailing between that port and Dover.

Railroad in Holland.—Some time ago the government of Holland applied to the States-General for their assent to the formation of a railroad from Amsterdam to Arnheim, by Utrecht, with a branch to Rotterdam; but the representatives, alarmed at the heavy charge it would create, rejected the proposal. It appears, however, that the King has resolved to undertake this great work by himself; for the *Staats Courant* of the 1st instant contains a royal decree for the construction of this road, which is to be ultimately prolonged to the frontier of Prussia. For accomplishing the first branch of the work a loan of 18,000,000 francs, with subsequent loans of 12,000,000 and 6,000,000 of francs at four one-third per cent., is to be raised, and secured, in the first instance, upon the produce of the railroads, and, in case the proceeds should be insufficient, upon the private property of the King, who thus makes himself guarantee to the subscribers. The decree goes on to stipulate that one fourth of the surplus receipts from the road, after payment of the interest on the sum advanced, shall be divided among the holders of bonds, and the remaining three-fourths applied in reimbursements of the capital advanced by means of drawings, with a premium or bonus of four per cent., till the whole sum advanced is paid off. When the loan is entirely discharged, the railroad, with all its appurtenances, is to become the property of the state. The period for issuing the bonds of the first series of the loan is to be fixed by the King, but it is to be raised in the course of the present year. The second series of the loan, however, is not to be opened before June 1839, nor the third before June 1840.

St. Petersburgh, April 25.—An accident has happened on our iron railroad to Zarskojeselo, the shares of which we noted in our price current so much below their original value, which is not calculated to raise the price. Yesterday was fixed for the imperial court to make an excursion on the railroad to Zarskojeselo. Their Majesties had given numerous invitations, and on the day before yesterday the officers of the household, with the necessary plate, &c., proceeded to the palace by the railroad; one of the family carriages which conveyed the plate was set on fire by the sparks from the chimney of the steam-carriage, and the engineer being so confounded that he paid no attention to the cries of the passengers, they leaped from the carriage, which was burnt with all its contents, including silver plate to the value of 30,000 roubles, which [illegible] seriously. His Majesty yesterday made an excursion on the railroad as an encouragement to the company, which was in consternation at this event. The *fête* of Zarskojeselo, countermanded yesterday, will take place to-day, but such measures will be taken that no similar accident can occur.—*Prussian State Gazette.*

Suez and Cairo.—The following is an extract from a letter dated Cairo, March 18, from Colonel Barr, Bombay army, who is making arrangements for improving the communication between Suez and Cairo, which he expects to reduce to an easy journey of 18 hours:—"We have, I think, arranged for three carriages, something of the omnibus kind, but capable of being thrown open at the top, to be in readiness for the passengers of the October steamer, also for the half-way house and mule station; the expense of the whole not to exceed the funds at my disposal (2,000*l.* from the Bombay Steam-fund Committee), and if the Pasha build the house, &c., it will leave us 500*l.* disposable for the improvement of the conveyance, tank, or buildings, as may be required."

The Pontine Marshes.—A letter from Rome, dated April 26, speaking of the arrival in that city of the Grand Duke of Tuscany, says—"He came through the marshes by way of Civita Vecchia. By his truly paternal care, not only have good roads and bridges been made there, but drains have been constructed, so that the fertile tract is nearly dry, and the inhabitants, whose numbers annually increase, now enjoy good air instead of the former ill-famed Aria Cattiva."

Navigation of the St. Lawrence.—Montreal, April 28.—The La Chine Canal is expected to be opened in about two days.

Gibraltar.—On Thursday, the 16th ult., the foundation-stone for a new lighthouse, on Europa Point, was laid by the Governor, Sir Alexander Woodford, K.C.B., &c., with masonic and military honours. The light-house will stand on a platform 38 feet square. The diameter of the column at the base will be 27 feet, and its height 60 feet. The building will be entirely constructed of hewn stone, and crowned with a lanthorn 10 feet high, with a very powerful light. It will thus form a very handsome object, as well as a most valuable acquisition.

MISCELLANEA.

Riddle's Universal Pen Holder.—Steel pens are now so generally used, that all have experienced the double annoyance of holders that will *not* hold when they are wanted, and holders that *will* hold when they are wanted *not*. The present invention seems likely to obviate both inconveniences. It is furnished with a moveable lower jaw, working with a spring which keeps it nearly a quarter of an inch from the upper one. Thus there is abundance of room to insert a pen either of quill or metal; even though not made expressly to fit; and there is little danger of its being set fast by the ink. The pen being inserted, a ring slides up over the jaw, closing the mouth upon the pen and keeping all tight. This holder is decidedly simpler than Bramah's, previously the best in use; and therefore preferable, as being less apt to need repair. The workmanship too, is as excellent as the contrivance is ingenious. We recommend it to all who use steel pens, and are content with a holder which does not attempt any of the numerous contrivances to give elasticity to them.

Ironmasters' Quarterly Meetings.—The *Staffordshire Examiner* states that an arrangement has been made by the ironmasters, merchants, &c., which will in future remove all uncertainty as to the time when these meetings shall be held. "The rule by which they are now to be determined is, that the Birmingham quarter-day shall in all cases be the second Thursday in the month following the Christmas, Lady-day, Midsummer, and Michaelmas quarters; that is, that it will be the second Thursday in January, April, July, and October. So that, instead of being determined by the variable feasts, as formerly, they will now follow a fixed, well-known, and invariable rule. By this arrangement there will always be a clear week after the close of the month to allow for posting up accounts, as the quarter-day can never fall earlier than the 8th nor later than the 14th of the month Of course the Wolverhampton, Walsall, Dudley, and Stourbridge quarter-days will be determined by that of Birmingham. The following, therefore, will be the quarter-days at these places for the two ensuing quarters of this year:—Walsall, Tuesday, July 10—Tuesday, October 9;—Wolverhampton, Wednesday, July 11—Wednesday, October 10;—Birmingham, Thursday, July 12—Thursday, October 11;—Stourbridge, Friday, July 13—Friday, October 12;—Dudley, Saturday, July 14—Saturday, October 13."

There is a work now exhibiting at the Egyptian Hall, which is of its kind unique; an enormous specimen of *metallic embossing*, being a copy of Lebrun's well-known picture of the Battle of Arbela, in copper; and, what is more remarkable, the work of a single hand. The artist is a M. Joseph Szentpéterq, silversmith of Pesth; the labour, we are told, occupied four years, and must have been immense, for not only is the crowd of figures enormous, but the relief required to throw them out so bold, as to offer difficulties which, at first sight, would appear insurmountable. Patience and genius, however, will prevail at last. It is said that after having been at work for two years on the subject, the artist was compelled to relinquish his plate, owing to a flaw in the copper, and to recommence his minute task; so satisfactorily, however, did he at last terminate it as to have been admitted, in right of its excellence, an Honorary Member of the Guild of Jewellers at Vienna. We should be glad to hear of this work finding a purchaser in one of our noble amateurs.—*Athenæum.*

NOTICES TO CORRESPONDENTS.

Mr. Lister's communication came too late for insertion in the present number, but shall find a place in the next: we shall be happy to receive from him any farther communication.

The account of Messrs. Price and Manby's apparatus, and other papers, are postponed in consequence of the crowded state of our columns.

We shall feel obliged to the Profession, for accounts of works in progress; particularly in the country.

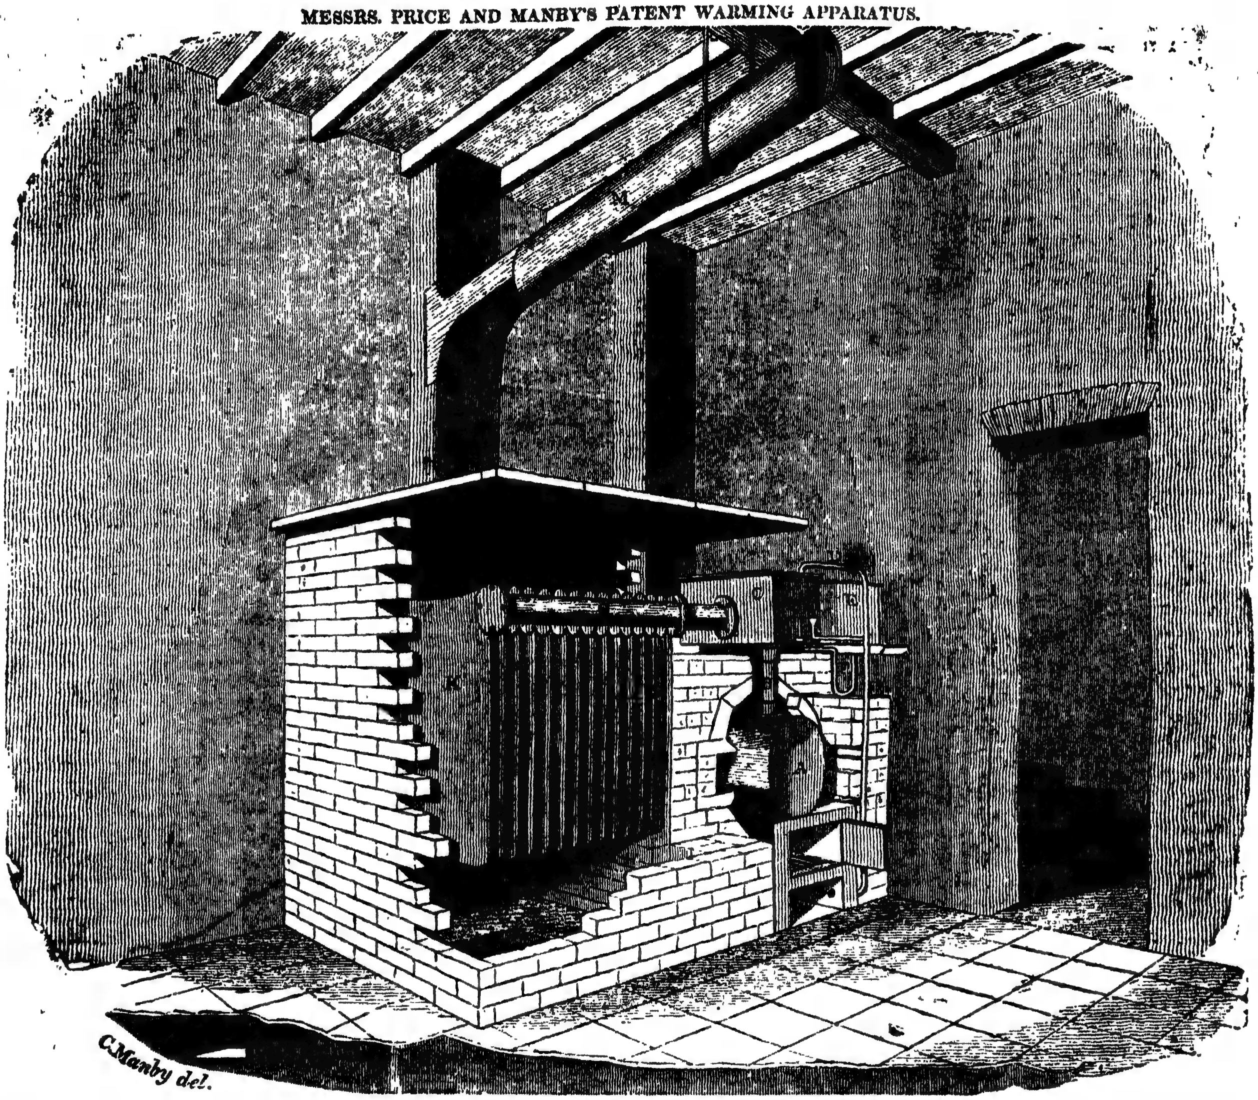
The first number of the Journal, will be reprinted and ready for delivery on the 14th inst.; when complete copies may be had.

SCHOOL FOR THE INDIGENT BLIND,

ST. GEORGE'S FIELDS.

(Continued from page 212.)

MESSRS. PRICE AND MANBY'S PATENT WARMING APPARATUS.



We recur to this building, in order to redeem our pledge of exhibiting the system of warming and ventilating adopted in it. The "Patent warming apparatus" of Messrs. Price and Manby of Bristol, and John Street Adelphi, is employed for this purpose: and we are enabled by the kindness of the Patentee, to lay before our readers a full description of the apparatus, illustrated by a drawing. The other drawings referred to below, will be found in the last number of the Journal, pp. 209, 210.

A is a wrought iron boiler set in brickwork, part of which is removed to show more plainly the construction: underneath, is a furnace with bars and door as usual; and lowest of all, a cast-iron ash-pan, kept constantly full of water for the purpose of preserving the bars, as well as assisting combustion by the steam raised by the falling ashes. Above the boiler, and connected with it by a vertical pipe B, is an expansion box C; whence a horizontal pipe G, leads to a series of narrow cast iron vessels K, placed vertically in a brick chamber, leaving a certain narrow space entirely open between each pair. This brick chamber is provided with a flue, opening in its bottom, to admit cold air freely from the outside; and with another rising from the top, to take off the warm air for use. A branch of this warm air flue is shown at M: such branches are of course provided in size and number proportionate to the rooms to be heated. The flues are made of zinc plate; they are coated with wooden covering boxes, the intervening space being well rammed with saw-dust: the amount of protection needed must be determined by the degree of exposure to which the flue is liable. Each of the water vessels K, is connected at bottom with a pipe communicating with the lower part of the boiler, and thus completing the circulation. The whole circle of pipes and vessels described, is supplied with water from the feed cistern E, by means of the syphon pipe F. A ball cock in this cistern keeps the water at a uniform level.

The apparatus being thus ready, a fire is lighted under the boiler: as the water warms, it rises through the pipe B into the expansion box C; thence it passes by the pipe G into the vertical vessels K, from the lowest parts of which, the coldest water of all constantly passes through the connecting pipe to the bottom of the boiler. This circulation will evidently be kept up, so long as any difference of temperature exists; whether that difference arise from the gradual heating of the boiler on lighting the fire, the gradual cooling after the fire has gone out, or the action of the cold air on the water boxes K. The circulation attains its greatest velocity when the water in the boiler reaches the boiling point, beyond which it is not carried. To guard against the danger of exceeding the proper degree of heat, the expansion box C is furnished with a pipe D, brought down so as to open into the ash pit, as shown in the drawing. Thus the steam necessarily arising from water kept constantly as near as possible to the boiling point, is disposed of; partly in the form of water supplying the ash pan, partly in the form of steam assisting

the combustion of the fire. A thermometer is attached to the front of the expansion box, to indicate the temperature of the water within.

Such is the circulation of the water; that of the air remains to be described. It enters the hot air chamber, as we stated above, at the bottom, under the water vessels K. The air in contact with the lower part of these vessels is heated by them, and consequently rises between them, meeting in its progress with parts hotter and hotter, till it attains its greatest temperature as it escapes from them to the flue at the upper part of the chamber. To supply its place, a constant stream of fresh air pours in from the lower flue. The temperature of the air as it quits the hot air chamber is about 130 deg.: in passing along the flues it loses from 20 to 30 deg.; and enters the rooms which it is designed to warm, at from 100 to 110 deg. It mingles almost imperceptibly with the air of the room; no current is felt at a very short distance from the regulator by which it enters; and while within the regulator the thermometer has been observed to stand at 100, at a distance of 18 inches it has been found only at 65.

The introduction of a body of warm air into a room in the manner described, necessarily implies the abstraction of a similar amount of air to make room for it. The air thus removed may be made to supply the warm air chamber of the stove; in which case less heat is lost. But at the same time no ventilation is gained, the same air is used over and over again: this mode then is applicable only in cases where there are but few persons to breathe the air, in proportion to the size of the room. In the instance before us, ventilation being very desirable, the air ejected by the constant influx of the warm air is conveyed away by ventilating flues, &c. The system of ventilation thus carried into effect, we proceed to describe: it appears very complete and very simple.

To consider first the arrangement in the Eastern wing, where the girls' work-room is warmed by Mr. Price's apparatus. S, fig. 4, is the furnace room in the cellar beneath the floor shown in the plan, the boiler being represented by the parallelogram, and the vertical water vessels by the series of parallel lines. The heated air rises through a flue which enters the work room H, by an aperture at *w* at the height of about 4½ feet from the floor. At the other end of the room, six holes, *vv*, fig. 3, are provided just above the floor, communicating with ventilating shafts, built in the walls. These holes will be seen better in fig. 9; where they are shown, three on each side of the door; with corresponding apertures *vv*, &c., above the upper ceiling, whence the vitiated air is discharged through Louvre openings. It will be seen then, that the circulation of air in the room is complete; the fresh warm air at the one end constantly entering, and a corresponding quantity of colder air constantly escaping after use, by the ventilating holes on the level of the floor at the other end. The flue from the hot air chamber, rises beyond the opening described as admitting it into the work-room, and terminates in a grating *w*, in the dormitory E, fig. 7. The opening into the work-room being closed when the day's work is over or the room warm enough, the heated air finds its way into the dormitory, which is thus likewise warmed.

In the centre compartment of the building, another apparatus is placed in the cellar under the kitchen, N, fig. 3. Its position is there indicated by dotted lines; but it will be seen better as shown in section, in the cellar at the right side of fig. 10. From the warm air chamber of this apparatus, flues lead off right and left to *w*, *w*, regulators in the centre of the floor of P and O, fig. 3, the boys' and girls' dining rooms. Ventilating holes *v*, *v*, &c., are provided in the ceilings at the farther ends of the rooms. Another flue is carried to the chapel or music room on the first floor, A, fig. 6, which it enters by the regulators *w*, *w*.

Several rooms in the Western wing are warmed by a third apparatus placed in the furnace room S, fig. 5. This room is but little below the level of the apartments on the ground floor; so that the regulators *w*, admitting the hot air into the boys' work-room K, are placed higher than in the former case, being about seven feet above the floor. The position of the ventilating shaft at the other end of the room is indicated at *v*, fig. 3. By this same apparatus also, two other rooms on this floor are warmed; the boys' washing room Y, fig. 5, by the flue nearest to the front wall of the furnace room S; and the shoemakers' room X, by the flue entering at *w*, the course of which across the gateway and along the ceiling of the washing-room, is indicated by the dotted lines. The boys' dormitory M, may like that of the girls be warmed at pleasure, by means of apertures in the floor furnished with moveable shutters, represented by *w*, *w*, figs. 6 and 8.

It will be seen at once, that the general principles of warming and ventilating here adopted are the same as those employed in connexion with the late Mr. Strutt's apparatus, better known perhaps as Sylvester's. These principles must in a great measure be common to all; but Mr. Price's apparatus certainly exhibits some important improvements on preceding contrivances for the heating of the air. The grand improvement is the employing of water as a means of heating the plates over which the air is to pass; for thus the danger of over-heating and burning the air is avoided, and the consequent smoke and dirt arising from leakages in the cockle, so frequent in Mr. Strutt's plan without the very greatest care, obviated. Still, some dirt comes over with the heated air; as may be seen on one or two of the ceilings, where the aperture for its admission is near the top of the room. As the hot air chamber, however, is perfectly separate from the furnace and smoke flues, we are inclined to agree with the patentee in referring this imperfection to the impurity of the air admitted. If it comes in, loaded with city smoke, it certainly meets with no means of purification in the apparatus. But a fine wire gauze across the aperture of the flue, is found to intercept these impurities very perfectly. Another advantage of the use of water, is that the heat is much longer retained: the action of the hot water goes on long after the fire is out; and the facility of keeping up the heat at night is considerably increased by the use of this circulating *medium*. The apparatus itself is ingeniously contrived with a view to obtaining in a small space a vast area of heating surface for the air to pass over.

To give an idea of the efficiency of the apparatus, and the expense of this mode of warming, the patentee has furnished us with the following account of the dimensions of the rooms; and the fuel used, is stated by him to be on an average about 1¼ cwt. per day for each apparatus.

In the East wing;—

	ft.		ft.		ft.	Cubic ft.	Cubic ft.
Girls' work room	117	×	25	×	15	......	55,125

In the Centre;—

Boys' dining room	52	×	25	×	16	= 20,800	
Girls' dining room	52	×	25	×	16	= 20,800	
Music room, of irregular shape					....	= 36,167	
							77,767

In the West wing;—

Boys' work room	165	×	25	×	15	= 61,875	
Washing room . .	37	×	21¼	×	15	= 11,793	
Shoemakers' room	37	×	21¼	×	15	= 11,793	
							85,461

In this account, it will be seen, the occasional warming of the dormitories is not included. It should be observed also that the number of windows is very considerable: 18 in the girls' work room, 19 in the boys'; 7 in each dining room; and 5, of very considerable size as our elevation shows, in the music room or chapel. Indeed the great extent of the building, and the vast amount of outside walls, present no slight difficulties to those who have undertaken to warm it. The apparatus in the Western wing has been in use two winters; we give below, such particulars as we have learned by inquiry on the spot, respecting its efficiency. We think it however but fair to state that this being the first, is probably the least efficient apparatus of the three. It is wished to keep the Boys' work room at about 54 degrees of temperature; which in ordinary states of the weather is effected without difficulty, except when the fire has been allowed to go too low at night. During the extremely cold weather of last winter, the freezing fresh air from the outside was not admitted to the stove, but the supply was taken from the room itself; sufficient ventilation being for once supposed to be gained by the numerous windows and the doors of the room. The washing room and the Shoemakers' room were also warmed; the latter requiring however an additional fire in the coldest weather. The dormitory does not seem ever to have had the hot air admitted. The consumption of fuel averaged about 2 cwt. a day, which agrees sufficiently with the account given above, as it will be seen that in the Western wing there is decidedly the greatest quantity of space required to be heated.

It is not however by the experience of one particular building that an apparatus like Mr. Price's is to be judged; and the public have before them abundant other instances of its use by which to form their opinion. From a long list of references, we select the following cases of the application of this apparatus, to the warming of buildings of various descriptions. In London: British Museum—Elgin and Egyptian Galleries; Pantheon, Oxford-street—the Bazaar; Messrs. Barnetts, Hoares, and Co., Lombard-street—Banking house. Bristol: Custom House—Long room. Liverpool: Mechanics' Institution—theatre, museum, and class rooms. Leicester: County Lunatic Asylum—galleries, day rooms, cells, &c. Birmingham: Town Hall—great room and corridors. Penryn Castle, Carmarthen, the seat of G. H. D. Pennant, Esq.—vestibule, great hall, staircases, corridor, dining room, library, keep, &c. The new Union poor-houses of Boston, Guildford, Horncastle, Louth, Buckingham, Oundle, &c.

REVIEWS.

History and Description of the London and Birmingham Railway. By Peter Lecount, F.R.A.S. and Thomas Roscoe; Part I.: London: Charles Tilt.

The commencement of this work augurs well for its success; and if the succeeding numbers prove equal to the first, it will be well deserving of public support. The four engravings in the part before us, are spiritedly executed. They comprise a view of the entrance to the railway at Euston Square: the viaduct over the river Colne near Watford, painted by G. Dodgson, in which the landscape is exquisitely drawn and possesses considerable spirit; a view of the Berkhampstead station; and another of the entrance to the Camden town depôt, showing the two stationary engine chimneys, &c. The letter press is also interspersed with some clever wood engravings of works on the line.

The first chapter commences with a comparison of the railway in respect of the magnitude of its works, with the greatest undertakings of ancient times.

The London and Birmingham Railway is unquestionably the greatest public work ever executed, either in ancient or modern times. If we estimate its importance by the labour alone which has been expended on it, perhaps the Great Chinese Wall might compete with it, but when we consider the immense outlay of capital which it has required,—the great and varied talents which have been in a constant state of requisition during the whole of its progress,—together with the unprecedented engineering difficulties, which we are happy to say are now overcome,—the gigantic work of the Chinese sinks totally into the shade.

It may be amusing to some readers, who are unacquainted with the magnitude of such an undertaking as the London and Birmingham Railway, if we give one or two illustrations of the above assertion. The great Pyramid of Egypt, that stupendous monument which seems likely to exist to the end of all time, will afford a comparison.

After making the necessary allowances for the foundations, galleries, &c., and reducing the whole to one uniform denomination, it will be found that the labour expended on the great Pyramid was equivalent to lifting fifteen thousand seven hundred and thirty-three million cubic feet of stone one foot high. This labour was performed, according to Diodorus Siculus, by three hundred thousand, and by Herodotus by one hundred thousand men, and it required for its execution twenty years.

If we reduce in the same manner the labour expended in constructing the London and Birmingham Railway to one common denomination, the result is twenty-five thousand million cubic feet of material (reduced to the same weight as that used in constructing the Pyramid) lifted one foot high, or nine thousand two hundred and sixty-seven million cubic feet more than was lifted one foot high in the construction of the Pyramid; yet this immense undertaking has been performed by about twenty thousand men in less than five years.

From the above calculation has been omitted all the tunnelling, culverts, drains, ballasting, and fencing, and all the heavy work at the various stations, and also the labour expended on engines, carriages, wagons, &c.; these are set off against the labour of drawing the materials of the Pyramid from the quarries to the spot where they were to be used—a much larger allowance than is necessary.

The second chapter carries on the history of the commencement of the undertaking, begun in the first: it describes the character of the country between London and Birmingham, exhibiting the difficulties which had to be surmounted; the various lines surveyed, and the one finally adopted.

The third chapter relates the proceedings before parliament, including the description of traffic proved as likely to pass along the line, and also the estimated cost of construction. Here the ingenuity of the author (we presume Mr. Lecount) is put in requisition, to account for the enormous difference between the estimate as laid before parliament, and the probable ultimate cost of the finished work. We cannot resist the temptation to lay before our readers, the case as made out by Mr. Lecount.

The Estimate laid before Parliament was as follows:—

Excavations and Embankments	£179,000
Tunnelling	250,286
Masonry	350,574
Rails, Chairs, Keys, and Pins	212,940
Blocks and Sleepers	102,960
Ballasting and laying Rails	102,960
Fencing	76,032
Land	250,000
Water Stations and Pumps	3,600
Offices, &c.	16,000
Locomotive Engines, Wagons, and Coaches	61,000
Contingencies	294,648
	£2,500,000

Before drawing to a conclusion with the present work, we shall more particularly allude to the increase which has taken place in this sum. It will, therefore, be sufficient at present to say, by way of explanation, that in an undertaking of this kind there are certain works which are of a fixed nature, and which can be fairly taken at the current prices of the day; but there are also others variable both in quantity and price.

For instance, the engineer knows he has, at least, a certain quantity of earth to move, and that, as he crosses over or under a given number of public highways, he must have a determinate number of bridges. All these things are positive data for an estimate, and constitute the principal sums in what are called the contract works; these formed an item of 1,649,155l. in the revised estimate of the engineer, and they were actually let for 1,621,821l. or 27,334l. below the estimate; to this 76,160l. has to be added, for the extension from Camden Town, where the railway originally began, to Euston Square.

From the great increase in prices, which took place almost immediately after the letting of the works, no less than seven contracts were thrown on the Company's hands, and of course these were the most difficult and expensive parts of the works; and in each case, the directors had to purchase all kinds of implements and materials at a vast expense, including five locomotive engines, while, from the times at which these seven contracts took to complete them, there was very little possibility of transferring these implements (technically called the Plant) from one contract to another. This, although a very expensive process, was the only one to be followed, or the line could not be opened under at least a year beyond the time contemplated.

It is a well known fact, that from the great rise in prices there is hardly one of the contractors who has made a sixpence by the three years' labour, and some have absolutely lost money, but have spiritedly performed their engagements whenever it was possible for them to do so. The difficulties of particular works will be adverted to in a future place; in the mean time the reader may be reminded of another class—namely, the variable one.

The contract works, consisting of definite portions of the whole, being let, as the land agents advanced in their labours, a series of what are called extra works arose; these consisted of bridges over private roads,—of bridges to join lands severed by the railway,—of culverts, drains, watering places, new roads, gates, fencing, approaches to bridges, &c., forming a large portion of the whole, and which could only be ascertained as the agreements were entered into between the owners of the land and the Company's agents.

It is obvious the engineer can have neither a knowledge of the extent of these, nor of their cost, except in a very general way; he only gains full information as he has extracts sent him from time to time from these agreements, showing what has been consented to on the part of the company, and he then gives his orders for the various works to be done. It is evident therefore that the total cost of these constantly increasing and variable works, many of them, as in the case of bridges with extensive approaches, costing several thousand pounds, cannot be fully ascertained till the line is nearly completed.

Another variable class of items are those denominated additional works. These consist of alterations of various kinds which must constantly arise in all great undertakings, such as increasing the slopes in particular parts where, on cutting into the ground, it is discovered to assume a different character to that of the borings taken right and left of it, from which borings alone could a judgment be formed in the first instance; in some cases springs of water are cut into, and have to be drained, in others rock is come upon, where no geological indications, or any result from the borings, would lead any one to suspect its proximity; from similar causes bridges have to be enlarged in their foundations, and where the slopes have been increased, in their superstructure also; water has to be procured for the adjoining occupiers of land at a considerable expense; and there is a constant and unavoidable increase in the outlay from these and other causes, over which no human foresight could, by any possibility, have the least control.

The description of the railway, considering the number of interesting works on the line, will we think be very limited if the letter press of the five remaining numbers be not extended. We suggest to the publisher that an additional eight pages would not be lost in the sale of the work. And there are ample materials for filling up the extra space with information highly interesting both to the public and the professional reader.

Reply to "A few Plain but Important Statements upon the Subject of the Scheme for supplying Leeds with Water; by Henry R. Abraham of London." By John W. Leather. Leeds: 1836.

In a former number of our Journal (No. VIII. p. 184), we noticed Mr. Abraham's pamphlet; and gave rather a lengthened extract, without making any comment. We have since received the reply of Mr. Leather, the other candidate in the field; and we proceed to make extracts from his pamphlet in the same manner as we did from Mr. Abraham's. There is much useful matter connected with the supply of water, to be culled from the statements of both parties. We understand that the question in dispute has been referred to six eminent hydraulic engineers, who are to examine the correctness of the various statements, and to report their opinion to the company. We consider that this is a very wise act on the Company's part; and it will remove a heavy responsibility from the Directors.

I now proceed to Mr. Abraham's pamphlet; he says, page 5:—

"You have stated, 'that before the works can be completed, 210,000 per-

sons will require water.'—Mr. Leather's evidence in the Committee of the House of Commons."

Mr. J. W. Leather's evidence is here professed to be quoted. His evidence, however, was, that the works might be brought into full operation in 1841; that, at that time, there might be two-thirds of 142,000, or 94,600 persons, occupying 20,000 houses, wanting water; and, if we allowed 60 gallons per house (being about 12½ gallons per individual), they would require 1,200,000 gallons per diem.

He afterwards went on to say, that, in 1851, there might be half as many more, or 142,000 persons, occupying 30,000 houses, wanting 1,800,000 gallons per diem. Mr. A misquotes in the outset; but let that pass.

* * * * * * *

Mr. Abraham says, page 6—

"At Eccup and Alwoodley, near Leeds, there are springs of water whose conflux yields a run of 230 gallons per minute, independent of any assistance from rain: this gives 18,165,050 cubic ft. per annum."

230 gallons per minute gives 19,397,946 cubic ft. per annum, when correctly calculated. I notice this merely incidentally. A gentleman claiming such superior accuracy, and actually going to half a gallon in his assumption of data, should be careful that his results do not show an error of upwards of a million cubic ft. But the discrepancy between his present and his former statement is many millions of cubic ft. In his Report, jointly with Mr. Mylne, dated August 31 1835, he says—"Upon examining the account of the weekly gauges of the various springs which unite in the Eccup Beck, the fluctuation appears to guarantee at its minimum flow a quantity equal to 432,000 gallons *per diem*."—Now, 230 gallons per minute being, in round numbers, nearly 332,000 gallons per diem, it seems probable that his error may have arisen from a mistake of the first figure: however, be his error where it may, it is clear that, in 1835, he stated the minimum flow of the springs at 432,000 gallons per diem, and this is equal to 25,301,668 cubic ft. per annum.

He then concedes that, besides the springs, we may get 11¾ ins. of rain into our reservoir, making, he says, 51,183,000 cubic ft.

We then have Springs	25,301,668	cubic ft.
Rain	51,183,000	„ „
Being a total of	76,484,668	„ „
The supply we stated as likely to be required in 1841 was	70,280,000	„ „
Leaving an excess of	6,204,668	cubic ft.

to supply evaporation from the surface of the reservoir.

Mr. Abraham, with minute accuracy, proceeds to calculate the amount of this evaporation. He tells you that "evaporation is and must be equal to the fall of rain." He then tells you that "in summer height $\frac{3}{10}$ of an in. is vaporized each day."

The result of a number of years' experiments by Dr. Dalton, Mr. Daniell, and Mr. Howard—three of the greatest names in the science of meteorology—state the maximum of evaporation to take place in July; the average of their observations giving about 4 in. as the quantity for that month. This gives an average of 0.13 in. per diem; it is, however, possible, nay probable, that, with a strong wind and a hot sun, evaporation may, on some days, amount to 3-10ths of an inch; but Mr. Abraham assumes this quantity for 90 days of summer. This would give - - - - - - 27 in.

He assumes $\frac{1}{20}$ in. for 90 days of winter, which would give - 4½ „

and $\frac{2}{10}$ .... 185 .... of autumn and spring - - 37 „

Making the total evaporation per annum - - 68½ „

He surely thought he was in the tropics!

Dr. Dalton's experiments	at Kendal,	for 3 years,	give 25.157 in. per annum.	
Mr. Howard's	at Tottenham,	8½ years	..	30.467 „
Mr. Daniell's	in London,	3 years	..	23.974 „

We might fairly take Kendal as being the most analagous to our district, not only in latitude, but in elevation above the sea,—consequently as most likely to assimilate to our district in its mean temperature, and other circumstances on which evaporation depends; but we will take the average of the three, or 26.53 in. It is therefore clear that 26.53 in.—say 26½, instead of 68½ in.—will be the quantity to be deducted for evaporation per annum.

But now a few words as to the extent of surface over which this evaporation is to take place. Mr. Abraham presumes that he has proved that our reservoir will never have more than 11,000,000 cubic ft. in it; while he assumes, in the data upon which this result is founded, that the reservoir will be nearly full. Mr. Abraham ought to know, that, in a reservoir to be formed by throwing an embankment across a valley, having converging sides, like that of Eccup, the surface of the water diminishes (though not in any precise ratio) as the cubic contents of the water diminish. I can supply him, however, with a few facts as data for any further calculations he may feel disposed to waste his time in making. In the situation where the Parliamentary reservoir is shown (though Mr. A. knows that we proposed to place it in a more advantageous position, as we so stated in our evidence):—

	Acres.	Cubic ft.	
If the water were 45 ft. above Will Redhoff's spring, its area would be	48½; its cubic contents	39½ millions.	
.... 40	40½	.... 29½	„
.... 35	30	 22	„
.... 30	26	 15	„
.... 25	21	 10	„

So that when reduced to 11,000,000 cubic ft. its area would be about 22 acres. But as this 11,000,000 cubic ft. is the maximum quantity of water which Mr. A.'s calculations (if they go to prove any thing) go to prove that we should have in our reservoir, he ought not to take so large an area. Half this area would be as much as Mr. A. ought to take, if he contends that he is right in his other positions; *i. e.* if he contends that we shall never have more than 11,000,000 cubic ft. of water, he must admit that we have not 40 acres exposed to evaporation.

If, on the other hand, he contends that we have 40 acres exposed to evaporation, he must admit that we have 30,000,000 cubic feet of water.

But to return to real quantities. I will not affect an accuracy which the subject does not admit of, by pretending to separate the seasons. But I will allow (and I am sure it is a liberal estimate, seeing that the reservoir will have least area when the vaporizing power is most active), that, on the average of the whole year, we shall expose 20 acres to this power.

We still want one further correction before we ought to satisfy Mr. Abraham's precision in estimating the quantities. It is clear that "filtration, irrigation, and evaporation," can stop none of that rain "in its meanderings and lazy percolations towards the reservoir," which actually falls upon the surface of the water. And here too, even the dew (of which more anon) will make, without deduction, its slow but sure deposit of 5 inches per annum.

We have only taken half the rain in the above estimate. We shall therefore have, towards compensating the evaporation, the other half of the rain, viz. 11¾ inches, and the dew 5 inches, making 16¾, or 16.75 inches; which, deducted from 26½ inches, or rather from 26.53 inches, (I beg Mr. A.'s pardon, it behoves me to be precise when dealing with gentlemen who go to half a gallon,) leaves 9.78 inches as the excess of evaporation over the compensating corrections. These 9.78 inches upon 20 acres, give 710,028 cubic ft., as the real probable quantity of uncompensated evaporation. Mr. Abraham states the quantity at 9,456,150 cubic ft.

We have then to deduct this quantity from the gross excess of the supply beyond the demand, viz. *vid. supra*	6,204,668	c. ft.
Deduct evaporation	710,028	„
Leaving the net excess	5,494,640	„

Or, in round numbers, about 5½ millions of cubic feet.

But Mr. Abraham tells you that above 7,000 000 cubic ft. will remain in the Eccup reservoir which cannot be drawn off. Fortunately he gives his *data* for this calculation. He says—p. 12—"A reservoir is to be formed at Eccup, 45 acres in area. The conduit from this is to be two feet from the bottom, and the conduit itself 30 inches in diameter—and it should have a head of a foot to work with; then above 7,000,000 cubic ft. must be deposited before the service can be carried on with regularity."

Now one foot deep upon 45 acres gives 1,960,200 cubic feet: it is therefore clear that Mr. Abraham has calculated upon the loss of between three and a half and four feet over the whole area of 45 acres. I have shown above that when the water is drawn down to 25 feet above Will Redhoff's spring, its area is reduced to 21 acres; and, when it should be drawn down to only four feet above Will Redhoff's spring, its area would be reduced to little more than half an acre—6-10ths of an acre. Then 4 feet is the depth at the deepest point, (round the perimeter of the water the depth is nothing, the water meeting the ground,) therefore, 2 feet average depth over 6-10ths of an acre, or 52,272 cubic feet, would be the real quantity, instead of upwards of 7,000,000 cubic feet, as Mr. Abraham has stated,—taking all Mr. Abraham's data, except his erroneous assumptions of uniform depth over an area of 45 acres.

Mr. Abraham knew, however, that we purposed to alter the site of the Parliamentary embankment, as we so stated in the Committee of the House of Commons. We should so execute the reservoir that we could draw off the whole of the water when we so wished, and for the supply of the town, as much as is desirable, *i. e.*, within two feet of the lowest point of the reservoir. Instead of 7,000,000 cubic feet, or even 52,000 cubic feet, the quantity left in the reservoir would not amount to 20,000 cubic feet—or, 1-10th of a day's supply. With respect to the 3,500,000 gallons which Mr. A. states would be left in the Weetwood reservoir, it is only necessary to observe that there would have been a large quantity (though, like the other, it is greatly magnified,) had the reservoir been executed exactly as shown in the Parliamentary plan, but this we should remedy in execution, and no loss would arise.

* * * * * * *

And now with respect to the quantity of downfall water absolutely lost. Mr. Abraham's theory appears to be that "one-half" of the downfall (be that downfall what it may) is lost in "filtration, irrigation, and evaporation." Thus out of 23½ inches of rain, he allows that 11¾ inches may run off into our reservoir;—and, besides this, he allows us to recover (after "filtration") from the other half, the *minimum* flow of the springs. This *minimum* flow, taking his own account of 432,000 gallons per diem, amounts to about 6 inches of water per annum over our whole gather. He has, therefore, only 5¾ inches left for the support of evaporation and vegetation during the whole year; and, had he founded his calculation on a downfall of 20 inches or 18 inches—which, he contends, are probable occurrences—he would have shown, by the same process of computation, that evaporation and vegetation would only have 4 inches or 3 inches, in these respective cases, to depend upon.—A most strange theory truly! In such years as these he would find a woful want of "the dew."

Our calculation was, that evaporation and absorption for the purposes of vegetation would cause an absolute loss of 10 inches per annum, let the downfall be what it might; and that the excess of the downfall over this quantity (and this excess only) would be returned to us by the springs and living streams. Mr. A.'s theory (if we could have entertained such a theory) would have been very much more favourable to our case in a dry season than our own. Thus,

supposing a downfall of 22 inches, by our own notions we should get but 12 inches, while Mr. Abraham's theory would yield us 17 inches:—17 inches would exceed 1,200,000 gallons per diem, after allowing all deductions; and, therefore, we might contend that Mr. Abraham's theory had proved our case. But we cannot recognise such a theory.

The real question hinges on the probable amount of the downfall. We are taunted with not having ascertained this downfall. No engineer hitherto employed has ascertained this—no engineer, before ourselves, has even recommended the fixing of a rain gauge. How many years would you have to extend your observations before you could be satisfied that you had ascertained the minimum yield of your district? The proposition is absurd. You must proceed on some assumption, and it is only necessary to show that our assumption is within the bounds of probability.

In reading an article on Meteorology or Rain some years ago, I had noted, from Rees's Cyclopædia, the fall of rain at several places; and I had noted also, a general observation that the average rain for England was 31 inches.* This note was made without any reference to my evidence on the Leeds Water-works: but, when I came to consider the subject with that view—when I considered the circumstance of our district being a tract of high and undulating ground, and forming the ridge between the valleys of the Wharf and the Aire—when I examined the quantity of rain falling in other places of which I had returns—when I compared the circumstances of these places and of our own district, and weighed well their analogies—I judged (and I trust I can satisfy you) that the assumption of 31 inches in our district was most reasonable.

Mr. Abraham tells you he has observations of the rain falling in a wet adjoining county—Lancashire; but he mentions no place. I can give you the results of observations made at several places in this wet adjoining county.

	Inches.
Dr. Dalton's observations for twenty-five years at Manchester, give	33.87
Observations for 18 years at Liverpool.....	35.10
.... 10........Lancaster......	45.00
.... 15........Townley	41.50
.... 2........Crawshawbooth	60.00
These places are all in Lancashire.	
Again, Obs. for 9 years at Kendal give ..	56.20
...... 7........ Keswick	67.50
...... 3 Garsdale, Westmorland	56.30
...... 3 years at Fellfoot ,,	55.70
At the gauge of the Sheffield Waterworks Company above Sheffield, there fell, in 1836	45.90

I might, with as much fairness, have adduced the above places in proof that my quantity is under rated; and indeed, with more of analogy on my side than Mr. Abraham has when he brings York and London, to show that this quantity is over-rated. Look at the situation of York, which, as Professor Phillips says†—"stands in the centre of perhaps the most uniform "and extensive vale in England, reaching from the mouth of the Tees to the "estuary of the Humber, a length of 70 miles, with a breadth of from 15 to "25 miles. In this vast space, no ground rises more than 100 or 150 ft. "above the level of York; and the Minster, elevated 200 ft. from the ground, "looks down upon an area of above 1,000 square miles, in which hardly any "object, whether of nature or art, rises to within 100 ft. of its summit."

"To this peculiarity of its geographical situation," he says, "we may "probably attribute the remarkable general regularity of the curves of mean "temperature at York:" and yet, even here, Professor Phillips's observations for 1833-34 give 25.7 inches.

Turn, on the other hand, to our district—a tract of high ground of very undulating surface—the ridge between the Wharf‡ and the Aire—having a deep valley on either side—just the circumferance to call into full activity the real sources of rain,—"to say nothing of the unequal circumstances of humidity in the different strata of the air, the incessant play of the currents "generated by the inequalities of the surface must incessantly mingle toge- "ther volumes of unequal temperatures, and thus create a greater amount of "rain than could be produced" in the lower and more level situation of York, where more uniform laws prevail.

In a year in which only 24 inches of rain should fall, we should have, according to Mr. Abraham's own theory, about 18 inches available for supply, and this would yield us 1,333,800 gallons per diem. I stated in my evidence that I had no doubt this quantity might be depended upon from the Eccup source; and "I thought it probable that, by the construction of a sufficiently capacious reservoir, the still higher quantity of 1,800,000 gallons might be secured without the aid of any auxiliary source." We further stated that the gather to our reservoir might be increased, if found necessary, by cutting a catch-water drain; which, with the friendly disposition of Lord Harewood, we thought might be done without any further Act of Parliament. I therefore trust that I have allayed any fears which Mr. A. may have excited, and that I have proved a high probability, to say the least, that the Eccup source will be sufficient for the requirements of the town for many years to come.

* Dr. Dalton gives it 31.3 inches.

† Report of Third Meeting of British Association for the Advancement of Science.

‡ Wharfdale is proverbially wet.—As an illustration of this popular opinion, I may quote the questions put to me by an Honourable Member—who was born and brought up in Wharfdale—when under examination in the Committee of the House of Commons:—

Mr. John W. Leather, examined by the Committee—"Your district is on the edge of Wharfdale? Yes.

"Do you think there is any place in the kingdom where there is more rain falls than in Wharfdale? I think there are places where more rain falls.

"Do you know another? I should say that at Keswick, Kendal, and other places in Cumberland and Westmoreland, more rain falls than in Wharfdale."

We received too late for notice in our present number, Mr. Abraham's rejoinder, from which we design to make some extracts on a future occasion.

Remarks on the disputed North-Western Boundary of New Brunswick, bordering on the United States of North America. By Captain P. Yule, Royal Engineers. London: Ridgways, 1838.

This is a pamphlet designed to attract public attention to a subject on which the author laments over public indifference and ignorance: his very title indeed conveys a tacit satire on popular ignorance respecting even the geography of our American colonies. He gives a very clear but concise account of the matters in dispute, and the various treaties and conventions on which they depend; the whole illustrated by a map marking very plainly the different lines of boundary proposed by different parties. A matter of this kind does not ordinarily fall within our province as journalists; though as Englishmen we feel an interest in the question, and as men we hope the disputing parties will find a rational and satisfactory settlement of the debate by peaceful argument alone. It happens however that even as journalists we are interested in this particular debate; for not only is the disputed territory important in relation to the integrity of our North American possessions, but we remember to have heard that a magnificent plan for a great Railway is necessarily postponed till this dispute be settled. The proposed line is designed to connect Quebec with one of the harbours of the Bay of Fundy; thus offering to the Canadian capital a harbour always accessible, and dispensing with the tedious and uncertain navigation of the St. Lawrence. Americans and English are foremost in the honourable race of mechanical improvements; they compare their railways with mutual advantage; they have of late mutually rejoiced in the success of the experiment which has brought their shores practically closer together: we firmly trust this difference, already of too long standing, will be speedily adjusted. And then we will give them at their own door a specimen of English railways,—willing alike to teach and learn.

Transactions of the Society for the encouragement of Arts, Manufactures, and Commerce: Vol. LI., part II. London: 1838.

This second part of the Society's transactions, contains as usual several interesting papers on various branches of Science and the Arts. There are however some of them more immediately connected with the objects of our Journal; and to these we shall confine our remarks.

But first we must be allowed to make a few remarks respecting the management of the Society itself. The mode of publishing the proceedings, we consider decidedly objectionable. On the present plan, none of the papers which have gained for their contributors the thanks of the Society, nor of the inventions rewarded by them, during the session of the present year, will be known to the public for from twelve to eighteen months to come. These, we conceive, should be announced forthwith; it would bring the Society more constantly before the public, and create a greater interest respecting their objects, were they, like other societies, to publish monthly brief abstracts of their papers. There must, we fear, be something radically wrong in the conduct of the Society, when we find further, that an income of 1,026*l.* is as stated in the accounts of the past year entirely expended in the support of the establishment, and that of this sum only a paltry 161*l.* has been distributed in rewards and prizes. For so praiseworthy an object, the Society ought to have a surplus of two or three thousands;—and we feel convinced that such would be the case, if they could but be induced to get rid of some of their antiquated modes of proceeding, and modify their plans so as to adapt them to the existing wants of the public. The designs of the Society are of the utmost public importance; much has been done by their means formerly in creating and diffusing a taste for the fine arts, and stimulating the progress of mechanical and manufacturing improvement; and we are fully convinced that much may still be done if the members will but resolutely exert themselves for the renovation of the Society.

We have however digressed somewhat (we hope not unpardonably) from the object of our review. To return then to the part of the Society's transactions at present before us. The paper on "Limestone and calcareous cements," by Mr. Aikin the respected Secretary of the Society, is deserving of an attentive perusal by the profession.

There is also a valuable practical paper, describing a "Method of building an obelisk without scaffolding," by Mr. T. Slacks of Lang-

holm, which is well deserving of notice. This paper and that of Mr. Aikin before mentioned, we shall notice again hereafter.

Mr. Wicksteed, the chairman of the Committee of Mechanics, has contributed a useful practical paper on the use of "Wooden wedges for water-pipes." This paper will attract attention to a mode of securing the joints of pipes, at present very little known, though it has been adopted for upwards of fifty years with complete success. To such of our readers as have not seen the Transactions of the Society, we cannot do a better service, than to give this paper in full.

The Thanks of the Society were voted to THOMAS WICKSTEED, *Engineer to the East London Water-Works, for his experiments on the application of Wooden Wedges to secure the Joints of Water-Pipes.*

Old Ford, July 14th, 1837.

SIR,—As the Society of Arts propose to publish my paper upon the method adopted by the East London Water-Works Company in making the joints of their water-pipes, I beg leave to add, that, although I consider it the best and most economical mode of making joints where pipes are laid *straight*, nevertheless (as it occasionally happens that in laying pipes, either to save bend-pipes where the curve is very slight, or by deviating from the straight line to avoid some sewer, or other obstruction, we are obliged to lay them so that the spigot end of the pipe does not enter the socket in a straight line) it is sometimes necessary to have recourse to an inferior material for the joint, as, for instance, lead, or iron cement. As, however, such cases happen but rarely—probably not one joint in a hundred—it will not be any objection to the adoption of wooden joints. I consider lead inferior to wood, because it is less elastic, and it is, therefore, more liable to be blown out than a wood joint, which, on account of its elasticity, has a firmer hold on the joint. And to iron cement, besides its want of elasticity, there are two objections; one, that it requires time to set before it can be safely exposed to a pressure; and secondly, if there should be a defect in the joint it must be made afresh, as it can neither be spiled as a wooden joint, nor set up as a lead joint.

There may be objections to a wooden joint in some cases, but in the majority of cases, if proper attention be paid to the quality of the wood, the form of the wedges, and care taken in making it, it is decidedly the best.

I am, Sir, &c. &c.

A. Aikin, Esq., Secretary, &c. &c. THOMAS WICKSTEED.

Old Ford, January 4, 1837.

SIR,—Having, for the last seven years, made use of wooden wedges, instead of lead, or iron cement, for the purpose of making the joints of our water-pipes, and considering that the great success attendant upon the renewal of this old method of making joints is worthy of being noticed, I propose to give you some account of it, that the Society of Arts may, if thought worthy of notice, make it more generally known.

Soon after I was appointed engineer to the East London Water-Works Company, Mr. Grout, one of the Directors of the Company, called my attention to the use of wooden wedge joints, stating, that joints had been so made at the Norwich Water-Works, for more than forty years, and had been found superior in stability to, and far less expensive than, lead or iron cement joints. I made some inquiries about them; and, amongst others, received information from an engineer at Newcastle-upon-Tyne, that they had been used in the collieries in that neighbourhood for above half a century. After considering the subject, I recommended the adoption of this method of making joints, although in opposition to the opinions of other professional gentlemen: the result has proved most satisfactory.

After having made use of the joints constantly for five years, I stated to some other engineers the result of my experience, and was answered by their saying,—that although there was no doubt that for *low* pressures—say, equal to 100 or 120 feet column of water—the wooden joints would answer; nevertheless, when exposed to a *greater* pressure of water—say, of 200 or 300 feet—the wedges would be blown out: I therefore tried the joints under a great pressure, and reported the result to the East London Water Works Directors, in January 1835, from which report the following is an extract:—

"I have, at various times, heard objections made to the wooden wedge joints adopted by the East London Water-Works Company, because it has been said, that the joints, under any extraordinary pressure, would be blown out; now as this, if correct, would have been a serious defect in the principle, I have thought it advisable to try what pressure they *would* stand.

"I caused two 3-inch, two 5-inch, and two 18-inch joints to be made, and placing the pipes, jointed, in the proving-machine at Old Ford, gradually increased the pressure, until it equalled a column of water of 733 feet* in height, without the joints being affected; when being perfectly satisfied with the result, I did not further increase the pressure, being fearful that the apparatus would break before I could blow out the joints; and I have no doubt that the pipes would have burst before the joint was destroyed.

"The only other objection that I have ever heard made to the wooden joints, has been a suspicion of their want of durability. In opposition, however, to this surmise, there is not only this principle, viz., that when wood is protected from the action of air and water (as is the case with the wood joint in that portion of it forming the wedge), it will not decay; but also the evidence produced by one of the directors, of the durability of wood joints at Norwich, and evidence which I myself received from Newcastle, and other places, of wood joints that had been made for fifty years, and were then perfectly sound.

"The joints that have been made for the last five years in the East London district are all good, and, in no instance, where care has been taken in making the joints, have they leaked.

"Before concluding this report I wish to observe, that the pressure to which the pipes were exposed in making the experiment was so much greater than that to which pipes are usually exposed, that it would, perhaps, be well to record the weight and thickness.

		Cwt.	qrs.	lbs.
"The 18-inch pipe was barely $\frac{3}{4}$ in thickness of metal, and weighed		11	0	0
The 5-inch	$\frac{1}{2}$	2	0	14
The 3 inch	$\frac{3}{8}$	1	0	14

"These pipes were exposed to a pressure of 733 feet column of water without bursting."

The following is a statement of the quantity of pipes I have laid for the East London Water-Works Company, the joints of which have been made with wooden wedges; and I have only to remark, that the repairs necessary have been very much less than those required upon lead or cement joints.

Bore.		Length.
3 inch	diameter	10,882 yards.
4	ditto	14,964
5	ditto	2,738
6	ditto	4,065
7	ditto	730
8	ditto	140
9	ditto	2,645
12	ditto	111
15	ditto	11
18	ditto	2,272
	Total	38,558 yards, or $21\frac{8}{10}$ miles.

The following Table will show the expense of joints, for one mile in length, of iron pipes of various bores, made of wood, iron cement, and lead:—

I. Bore of Pipes.	II. Cost of *Wood* Joints, for one mile in length, of various bores, as shown in column I.			III. Cost of *Iron Cement* Joints, for one mile in length, of various bores, as shown in column I.			IV. Cost of *Lead* Joints for one mile in length, of various bores, as shown in column I.		
inch.	£.	s.	d.	£.	s.	d.	£.	s.	d.
18	60	10	$8\frac{1}{4}$	135	14	$10\frac{1}{2}$	221	6	$11\frac{1}{2}$
17	56	5	1	128	8	$1\frac{1}{2}$	207	5	$8\frac{1}{4}$
16	54	8	$4\frac{1}{4}$	122	5	10	192	12	$2\frac{1}{4}$
15	51	7	3	115	11	$3\frac{3}{4}$	179	15	$4\frac{1}{2}$
14	48	18	4	108	16	$9\frac{1}{2}$	165	1	$10\frac{1}{2}$
13	45	17	$2\frac{1}{4}$	101	10	$0\frac{1}{2}$	158	7	$4\frac{1}{4}$
12	42	16	$0\frac{1}{2}$	75	16	5	120	9	$1\frac{1}{2}$
11	39	2	8	67	5	$2\frac{1}{2}$	101	10	$0\frac{1}{2}$
10	36	13	9	62	7	$4\frac{1}{2}$	94	3	$3\frac{1}{2}$
9	33	0	$4\frac{1}{2}$	56	5	1	86	4	$3\frac{3}{4}$
8	30	11	$5\frac{1}{2}$	48	18	4	76	8	$7\frac{3}{4}$
7	26	18	1	47	1	$7\frac{3}{4}$	67	5	$2\frac{1}{2}$
6	23	4	$8\frac{1}{2}$	38	10	$5\frac{1}{4}$	57	9	$6\frac{1}{2}$
5	21	8	$0\frac{1}{4}$	33	0	$4\frac{1}{2}$	49	10	$6\frac{1}{4}$
4	18	19	$1\frac{1}{4}$	26	5	$10\frac{1}{4}$	40	7	$1\frac{1}{2}$
3	16	10	$2\frac{1}{4}$	22	0	3	34	4	10
	606	11	4	1189	17	$11\frac{1}{2}$	1852	2	$1\frac{3}{4}$

From the foregoing table, it appears that the joints, for 16 miles of iron piping, varying from 18 inches to 3 inches, will cost, if made of wood, 606*l*. 11*s*. 4*d*.; if made of iron cement, 1,189*l*. 17*s*. $11\frac{1}{2}$*d*.; and if made of lead (20*s*. per cwt.), 1,852*l*. 2*s*. $1\frac{3}{4}$*d*., exhibiting a considerable saving in expense in the use of wood.

The material to be used for wooden joints should be the best Dantzic fir. A balk is cut up into chocks of 9 inches in length each. These chocks, having been riven with an axe into pieces $\frac{3}{4}$ inch thick by about two wide, are worked into the proper form by spoke-shaves curved to suit the inside of the socket, and outside of the pipe for which the wedge joint is required. Each 9-inch piece of wood, when worked and cut in half, makes two wedges, each $4\frac{1}{2}$ inches long.

Herewith you will receive a chock of fir, a piece riven ready to be worked into the proper form, one when worked, two wedges made out of one piece, and two spiles; also, a curved spoke-shave or drawing knife, and a set.

The joints are formed thus:—The wedges are introduced into the socket, and placed close to one another—each forms an arc of a circle, and is wedge-shaped; a set is then applied to the end of the wedge, and the workman strikes it with a hammer, driving the wedges in regularly and gradually all round (as a cooper hoops his barrels) until they are driven up tight; the ends, if any are left, are cut off with a hand-saw, so as to leave the joints flush. When as many joints are made as are required so as to allow time, before the day's work is completed, to fill up the trench and cover the pipes, a bonnet is strapped on to the end of the newly laid line of pipes, the water is admitted to the other end, and the joints exposed to the pressure of the water in the mains; a man then examines every joint carefully, and wherever there is an escape of water, he makes an incision with a chisel, and drives in a wooden spile, which immediately stops the leak. When the whole of the joints have been thus examined and made tight, the ground is filled in, and the work is completed.

* Equal to the enormous pressure of 318 lb. on the square inch!—ED.

From this description it will be seen that it is necessary to have some communication with pipes already charged with water, which is always attainable in established works. In new works it will be necessary to have a force-pump, or other means to prove the joints before the ground is filled in.

In lead joints the operation is,

1st. To introduce some gasket which is driven in tight all round, to prevent the melted lead from running into the pipe.

2nd. To melt the lead. A man and fire are required in this case, but not so in making wooden joints: hence a saving in materials and labour.

3rd. To form a clay mould.

4th. To run the lead in.

5th. To set up the joint.

With the foregoing description and tables, aided by the specimens referred to, and a specimen of one of the joints when made (of which specimens I beg the Society's acceptance), I trust the advantage, in many, if not most, cases, of this description of joint will be perceived.

I am, Sir, &c.,

A. Aikin, Esq. THOMAS WICKSTEED.

Index to the Times, for May 1838. London: James Wyld.

For fulness of information on all possible subjects, the Times has long held a high and well-earned reputation: for statistical facts especially, its file is constantly consulted by men of all parties and of all occupations. An index like the present is much wanted, to diminish the labour of reference; it is full, well arranged, clearly printed and cheap. Every one will look to his own particular topic of interest to judge of the merit of the work: and we looking to the head of "Railways," find the news of the month on this subject most clearly drawn out and referred to. Under the head of London and Birmingham for instance, we find the completion of the front; various complaints about the mode of carrying on the traffic, which have appeared in the Times during the month (with what justice, is nothing to our present purpose); and the conveyance of the mails. We find numerous foreign railways noticed in various stages, from the debating whether they shall be made, to their final opening. So also, English legal intelligence in great variety; and the progress and working of numerous railways at home.

We view this index as a specimen: and from its execution, and its evident utility, we cordially wish the publisher the success which his spirited undertaking so justly deserves.

ORIGINAL PAPERS AND COMMUNICATIONS.

RALPH REDIVIVUS—No. 7.

THE POST OFFICE.

Let us just step across the way,—I mean cross over from Goldsmiths' Hall to the Post Office,—a moderately short cut, especially when it is considered that it carries, to the antipodes, Sir Robert Smirke's Grecian being diametrically opposite in taste to Mr. Hardwick's Italian. "Cross over," is, perhaps, an ominous expression, for it almost seems to say that I am going to be cross myself; it shall therefore be "let us go round" and look at the façade. There is no occasion for us to take our station so as to behold at the same time the north end of the building, because there is no particularly classical gusto in that; on the contrary, it partakes more of a Quaker's drab bonnet than of Athene's helmet.

Having fairly passed that corner; we may now pause to contemplate the front. According to Wightwick, whose opinion ought to stand for something, "there is a severe tone of classic propriety about it which almost awes criticism into silence. Smirke has here emulated the true nobility of Athens and has 'done the deed' of which an Ictinus might be proud." That the portico is a noble feature, that it is executed upon a grander scale than almost any other, that it displays itself to very great advantage, and that all the rest is kept quite subservient to it, are points I do not intend to dispute. Neither can exception be taken to the general composition; which must be allowed to have an air of dignified simplicity arising from continuity, regularity, breadth of masses, and magnitude. Still as far as design alone goes, I am unable to discern anything more than sober discretion, and correctly calculating taste, without aught that gives evidence of either superior mind or any imagination and invention on the part of the architect himself. If he shows himself correct, it is because he is exact, and adheres as rigorously as it is possible to do to the express forms and features of the antique, carefully abstaining from introducing besides more than circumstances absolutely compel him to do.

Oddly as it may sound to those who hastily adopt current opinions, it is possible for a building to possess much merit, though the architect himself may not possess at all greater talent than those whose works exhibit greater incorrectness and more inequalities; nay, very probably, he may not happen to be gifted with so much. The secret of this is, that as far as circumstances will allow, he confines himself steadily to some approved pattern, without venturing, if he can possibly help it, to introduce a single idea that can be mistaken for his own. What is the consequence?—this abstemious cautiousness, which more likely than not ought to be ascribed to sluggishness of imagination, procures for him the reputation of being exquisitely classical and chaste, although in any other art a similar system of copying would procure for him who adopted it, the unenviable sobriquet of Sir Facsimile Plagiary.

It is rather inexplicable, why so much stress should be laid upon scrupulous fidelity to extant classical authorities, precisely in that very art where fidelity may be accomplished by unerring mechanical rules, without demanding that species of skill which is necessary for producing a faithful copy of a fine original in painting or sculpture. Not only do we most barefacedly copy the individual and component parts, as far as ancient examples will supply any applicable to our purposes; but we make no scruple of taking them by wholesale, without studying how to give them any degree of newness by combining them differently. We do not employ them as words, which are common property in a language, in order to express our own ideas; but take ideas and all, repeat the very expressions, and thereby reduce architectural composition to the level of a mere happy knack in quotation.

Were no merit whatever arrogated, such a system would be less offensive; but when we find so much pretension go hand and hand with the most undisguised practice of purloining ready made-up materials, we may be excused—not for being magniloquently indignant at it,—but for smiling at the excessive simplicity of the public who lifting up their hands with to-be-wondered-at wonderment exclaim what conceptions! what genius! has Sir Facsimile. Surely it would be but decent were those architects who show themselves to be no more than compilers to abate a little of their claim to the title of artist. In the republic of letters—whose motto may be "Fraternity" but certainly not "Equality,"—the dictionary-maker does not pretend to place himself on the same form with the poet,—nor for the matter of that, even with the puniest novelist—I might say not even with the puniest punster, though as far as serviceableness goes he may be worth more than poet, novelist, and punster, all three together. In architecture on the contrary, men actually pique themselves on doing that which however it may show their taste, most assuredly does not

display any talent on their part. To say the truth, design is thus reduced to what any amateur who is master of his pencil, can accomplish equally well,—in proof of which, we might refer to the idea published some years ago by Mr. Kelsall, alias Mela Britannicus, for rebuilding Windsor Palace in the Grecian style.

On the first introduction of the genuine Athenian and Hellenic architecture among us, it was no more than desirable as well as natural that we should conform strictly to the various examples of its orders: yet that is no reason wherefore we should continue to do so, now that we are well acquainted with them, repeating over and over again precisely the same forms, to the exclusion both of variety and individual character. Either we have been studying them all the while to no purpose; or we ought by this time to have sufficiently imbued ourselves with the spirit of the originals, to be able to preserve it without servilely transcribing the very patterns themselves, and to communicate it to what is conceived with artist-like freedom. So then! I recommend it seems that we should abandon those models, and give ourselves up entirely to our own fancies! Very far from it; I recommend no such thing; all I protest against is the mechanical and unartistical practice of invariably giving fac-similes of them, or rather of one or two individual examples;—a practice the reverse of that pursued by the Greeks themselves, as is proved by the numerous varieties we meet with in their treatment of the same order. That some of them are much inferior to the others cannot be denied; but then this very circumstance itself is favourable to *us*, because it affords scope for the exercise of our own taste and invention, leaving to us the task of working up those less perfect specimens into more finished consistency and gracefulness. Besides, after all, what avails it to be so punctiliously and superstitiously exact in such particulars, when we do not scruple to take wholesale licenses in matters of far greater importance, as influencing general effect and character? I am therefore inclined to suspect that such scrupulous reverence for the antique is frequently no better than a pretext to cloke either indolence or something worse. Be that as it may, it is a pity that their reverence for the antique does not lead our architects to avail themselves of some of the capitals deposited in the British Museum. They are it is true but fragments; yet on that very account are they calculated to prove more valuable as studies, because while they show enough to serve as a theme, they leave it to the artist to expand the idea, and supply all the rest from his own resources.

By this time the reader perhaps smells out much strange heresy in my doctrine, which may, therefore, be impugned by the stalest arguments *ex adverso*. I do not however apologise for the above remarks, on any other ground than that of their being, although greatly too brief to serve as a full exposition of the matter itself, somewhat too lengthy for the present occasion, having detained me from commenting on what is professedly the subject of my present paper. Yet the building itself is of such negative quality,—with so little either of excellence or the contrary which can be attributed to its author, that it does not afford much opportunity for particular criticism. In itself it possesses, most unquestionably, the advantage of extent; and is commanding from its style, no less than from its size: and had it been erected a century earlier than it was, it would have been entitled to very high praise indeed, as manifesting a singularly pure and correct taste in comparison with what then prevailed. But at this time of day, when we have got the Greek grammar of architecture quite by heart, and know all its rules by rote, there is very little merit in applying them with tolerable correctness, where there is no ambition to achieve anything more.

We are told of Addison that his natural talents "were so restrained and disabled by his constant and superstitious study of the old classics, that he was in fact but a very ordinary poet." *Mutatis mutandis*, this will apply to the architect of the Post-office. Whatever imagination he may have of his own, he represses it so entirely, out of deference to his classic models, that he does not permit it even to betray any symptoms of its existence. So far from being ambitious of signalizing himself, he is content to act entirely as proxy for the ancients, doing nothing—as far as he can avoid it—for which he has not their immediate sanction. It is therefore an invariable practice with him to confine his attention exclusively to the order and the columnar parts; bestowing no other study on the rest, than how to render them as little conspicuous as possible, so as not to divert attention from what is principal in the design. Unfortunately however this tends to produce a result contrary to the one aimed at; inasmuch as the disparity of character between the several parts of the composition, becomes in consequence all the more striking. The only novelty observable here is that the upper face alone of the architrave is continued along the parts between the centre and ends of the front.

In regard to the portico itself it is unexceptionable; it comes in, as a portico invariably ought to do, where it seems absolutely required to fill up the design, instead of being placed so as to look like an extraneous addition to the parts behind it. It is remarkable also for its spaciousness; for besides being brought out boldly forward, it likewise retires nearly as much within the building, and thus acquires more powerful depth of shade; added to which it looks in consequence more inseparably connected with and belonging to the rest of the edifice, than does one that merely juts out from it. The large door is a noble feature in itself, and loses nothing from being contrasted with the two smaller ones. Yet while I readily admit that every thing here is good, I cannot help also fancying that it might by a little more study have been rendered very much better: for instance, had what are now separate pedestals below the columns been made a continued stylobate, leaving only the present entrances at the extremities of the front of the portico, it would I conceive have been a decided improvement; more especially had such stylobate been continued beyond the extreme pedestals, but brought forward upon the same line as, and in lieu of, the present palisading, which so far from being in any degree ornamental, is altogether the reverse, detracting very materially from the general appearance of the architecture, whereas a solid podium or low screen wall would have given not only a classical but a somewhat unusual character to the whole.

As to the Hall, I do not consider it by any means to be compared with the portico itself; so far from being pure in its style, it presents most offensive discrepancies. The east end, with its small arched doors and windows, is of a character quite inconsistent with that of the other; nor do those features appear to have been introduced with any other design than to make them agree with the windows of the same kind in the back front. Yet if there was no other alternative, it would have been better to sacrifice unity of style in a part of the exterior which makes little pretension to architectural display, than within the Hall itself; more particularly as the petty and objectionable features complained of, interfere with the effect of the portico itself, being distinctly seen through the great doorway. I might also observe that the sides of the Hall are little better than its east end; having a very ordinary, cold, and unfinished appearance in comparison with the columns. However, as I have now said in the way of praise all that my critical conscience will allow me to do; and in the way of censure enough, perhaps, to make others fancy I have no conscience at all, I will only add, *Basta!*

ON BUILDING MATERIALS.

NO. III.—CEMENT.

Although cement and lime are frequently employed in the same manner, nevertheless as the distinction between them is well known to the practical builder, I have thought it best to treat of them under separate heads, and shall confine myself in the present essay to a description of those substances which are most commonly employed in the external decoration or covering of buildings.

The practice of coating the exterior of buildings with some kind of artificial cement, in order to render it more durable or more beautiful to the eye, is undoubtedly of high antiquity: the temple of Jupiter Olympius at Agrigentum in Sicily, is erected of a loose coarse sandstone, and covered externally with a fine white substance, almost as hard and durable as marble; in the ruins of the city of Alexandria in Egypt, are the remains of some edifices coated with a cement which to this day is almost impenetrable to the chisel; and the remains of ancient Rome present many proofs of a similar practice.

In England cement appears to have been little used until the commencement of the present century, when Messrs. Parker and Wyatt patented the article commonly called Roman cement; which for many years was extensively used throughout the kingdom, although it is now partially superseded by the introduction of other substances. This cement varies much both in quality and price, but is never so good as when it was first introduced; it might then be used even during a sharp frost, but now few builders would venture to apply it at such a season. Whether this inferiority arises from the nature of the material itself, or from the mode in which it is manufactured, I am not able to determine; but certain it is that its quality has greatly degenerated within the last fifteen years. This cement is manufactured principally from stone found in the Isle of Sheppy: its colour is very dark, so that it requires frequently colouring, and it is very liable to crack in drying. It is best mixed with an equal portion of sand by measure, although sometimes two parts of sand to one of cement is preferable; the cement must however be then of the very best quality. Although a fine and almost impalpable powder, it is generally coarse when wet; and except when mixed with great care, can seldom be made to bear a very smooth face. Only a small portion of this cement ought to be mixed at a time, as it sets quickly and is of but little use

afterwards. Its principal value consists in its power of resisting the action of water, to which it is almost impervious very soon after it is applied; hence it is much used in coating the upper surface of brick arches, and lining cisterns and damp walls in basements of buildings. It does not however possess the power of resisting fire in the same degree, as a very moderate heat entirely destroys its tenacity: it is somewhat remarkable that this circumstance is frequently but little known to bricklayers; and I have several times seen ovens, coppers, furnaces, &c., set with it, and although I have warned the workmen of the certain consequence of its employment in such situations, my cautions have been treated with contempt, until experience has proved their correctness.

Atkinson's cement is very similar in quality to Roman cement, but is much better in colour: it does not however set so expeditiously, and it absorbs moisture more; in good dry situations, when used for ornamental work, it is certainly preferable; but for building purposes it is, I think, inferior.

Almost every kind of stone lime, if well burnt and used immediately, becomes a very durable cement; the oxygen of which it is deprived by the action of the fire is gradually re-absorbed by exposure to the atmosphere, and hence it in time becomes almost as hard as the stone from which it was originally manufactured. Of stone lime however, the blue lias is almost the only kind which is extensively employed in coating buildings, &c. When used as stucco, this lime is certainly superior to Roman cement; it is not so liable to crack or blister, and being similar in colour to stone, it does not require to be coloured. For the first coat it should, after being carefully screened, be mixed with about three parts of coarse sharp sand; and for the finishing, with two parts of fine sand to one of lime.

Hamelin's patent mastic is above all others the most durable and excellent substance for ornamenting buildings. This material is mixed with oil instead of water: it is very difficult to lay on properly, and requires considerable care and experience in order to make it attach itself firmly to the walls &c. The thinner the coating, the better; it should never exceed one-fourth of an inch;—ignorance of this fact has sometimes led to very disagreeable results. I was once shown the house of a gentleman which had been covered with mastic at a great expense, and from the walls of which it had fallen off in large patches, some above a yard square; this was principally owing to its thickness, it being in many places near an inch and a half thick. The Monument on North Down in the Isle of Thanet had its mouldings formed of mastic worked out solid; and in a very short time they nearly all fell off.

In London where mastic has of late been extensively used, a much better method is adopted; it is there usual to lay it on the walls in as thin a coat as possible, and all mouldings and other projections are first formed of Roman cement roughly, and then covered with mastic about one-eighth of an inch thick. When used in this manner, and the surface of the wall &c. previously properly prepared, mastic will become almost as durable as stone, and will last for ages. It is likewise capable of bearing the heat of the sun for a long time without cracking, and when carefully worked has a surface almost as smoth as polished marble: and should it require painting it can be done very soon after it is put on.

Various kinds of cement have been introduced at different periods to supersede the use of lead in covering flat roofs; of these none has hitherto been effectual, as they are all liable to crack and let in the water. In Persia, a cement for this purpose is formed of sand and a species of molasses, which resists the action of an almost vertical sun; and in Asia Minor, I am told that the flat roofs of the buildings are commonly covered with a layer of reeds, over which is spread a coating of cow dung and pounded sea shells, which in time becomes almost as hard as stone. The introduction of Asphaltum into this country will probably give a fresh impulse to attempts of this kind; although its inflammable nature is a great objection to its extensive use. As this substance is quite new to us, I shall refrain from giving an opinion upon it until practical experience shall have enabled us to judge more correctly of its merits.

C. L. O.

ON THE CLAIMS OF CIVIL ENGINEERING TO BE CONSIDERED AS A PROFESSION OF GENIUS.

By Hyde Clarke, Esq., C.E.

If there be anything which can be justly esteemed an object of rational pride, it is the contemplation of great works of public utility; which, whether they be erected by our ancestors or ourselves, are equally productive of pleasure and enjoyment. It is in such monuments that we appreciate the triumph of science over all other objects of competition. The greatest victory of the hero is but the precursor of his nation's downfall; the songs of the bard fall tuneless on the ears of those to whom the language is unknown; and the temples of the architect crumble into ruin, with the oblivion of the name to which they were consecrated: but the exertions of the engineer continue for ages to minister to the wants of successive generations, who although they may forget their constructors, will ever appreciate the utility of their labours. The site of Troy lives but in the pages of Homer; the eternal city is now the tomb of the same desolation which it once scattered abroad; but the roads of the Romans are as crowded as ever, and will live longer than the memory of their founders.

The engineer thus labours in the composition of works more durable than those of any class of artists; and he may be truly said to work for immortality, who labours not for this generation or this age, but for all posterity. The designs of the painter after many resuscitations fade for ever; the finest marbles of the sculptor perish, or their subject becomes forgotten; the ruined piles of the architect are torn from their position to construct new buildings; but the causeway of the Roman is the path of the Lombard and the Italian; while aqueducts for nearly twenty centuries have supplied to the Goth, the Moor, and the Spaniard, water from the fount from which the Romans drank.

As the compositions of the engineer are of this imperishable nature, so have they been appreciated by every people, as true sources of national grandeur and prosperity. The pyramids of Egypt were its least glory; gigantic canals transported to India the traffic of the world, or diffused plenty and abundance over the whole country. Among the Greeks, the triumphs of Alexander as an engineer were not less than his victories in the field; he built out the sea to join Tyre to the continent, and his efforts at Alexandria rendered that city long the emporium of Eastern commerce. With the Romans, the spade which dug entrenchments in time of war, gave strength to the country on the return of peace; nor were their exertions confined to Italy, but even to this day in Spain, France, and England, you still see unimpaired many of their roads, bridges, and aqueducts. In modern times this emulation in useful enterprises has not ceased; and the greatest men of all countries have vied with each other in the magnitude of their designs. One of the glories of Louis Quatorze, is the Canal of Languedoc; and the Emperor Napoleon conquered those Alps by magnificent roads, which he had previously surpassed by his incomparable genius. Peter the Great and the daring Catherine, Frederick of Prussia and the Emperor Joceph, all strove equally in the vastness of their civil works, as in the extent of their conquests.

How is it in this country and in America? It is felt that the people have imperishable treasures, in the works executed by their own energy or the prudence of their ancestors. It would be in vain that the powers of steam armed the manufacturer with magic facility of production, unless his textures were distributed to every part of the country by adequate communications, or conveyed to distant lands from the docks and basins of the coast. These glorious productions we may esteem as living monuments of our greatness. The writings of our poets may be read in foreign lands, the designs of our artists spread over the world by engravings; but the Caledonian Canal, Plymouth Breakwater, the Menai Bridge, or the Birmingham Railway, to be appreciated must be seen. It shows a purity and exaltation of taste, in which we are lamentably deficient, that while our nobility, gentry, and men of learning travel but to view works of taste or to dissipate time; it is always the principal object of foreign visitors and often their sole inducement, to see those transcendant testimonials of our engineering skill that are better known on the Continent than the brawls of our statesmen, the victories of our heroes, or the effusions of our writers.

Having shown the importance of this class of monuments, it is essential to estimate the merit that is due to their designer for his exertions in their production; and to consider how far the execution of these works is a matter of acquired skill, and how far of native genius. It is undeniable that the practice of Civil Engineering requires a high class of scientific attainments, many years of study, and a well instructed experience; but we should do wrong were we to imagine that the qualifications for the profession are confined to these requisites. Engineering is of all professions, the military excepted, that in which a new adaptation of expedients to unforeseen occurrences is ever most imperatively required; and in which a mere knowledge of past efforts will be insufficient, unless the mind be competent to invent new processes, as well as to avail itself in the best manner of old ones. No man can go upon a spot, and say I will do such and such things at such an expense; some unexpected variation of nature beneath the surface will often thwart the best calculated plans, and render all attempts at economy abortive: happy if the difficulties be surmounted, and the work be completed. It is genius only, and genius of the highest kind, which can properly preside over the just application of the fixed rules of science to the ever occurring variations which spring up in the course of an engi-

neering undertaking. What other power could have combated the circumstances which retarded the progress of the Thames Tunnel, and impeded the excavations on the Birmingham Railway?

Nor is this quality of genius confined to the execution of works, but it must be present at their suggestion. Any man can draw lines from one town to another, or survey the localities; but it requires an exquisite exertion of thought, properly to design a canal or a railway. Men of the greatest talent and experience will repeatedly fail in the formation of a harbour, and find all the resources of science fruitless and unavailing; because the circumstances of the case require new modifications of preceding theories, which they may prove incapable of suggesting. Who can go over a great public work without seeing the marks of some presiding genius imprinted at every stage, and without feeling his admiration excited by the contemplation of every new object? In the enthusiasm of the moment the name of the engineer may be asked;—but it is too often to be considered as an extravagantly paid mechanic, or a competent superintendent over excavators and bricklayers;—while the man who paints a portrait of some illustrious unknown, or erects a plagiarised building, is esteemed as having more genius, and as exercising a more liberal profession. This is not just: and a due appreciation of the circumstances would point out that the success of a great work is not dependent on parrot-like acquaintance with science, or mere mechanical skill; but that to the greatest acquirements must be united a degree of genius which can supply the deficiencies of the precepts of the art, and point out new tracks where none have passed before.

Discoveries and new applications in science and medicine have covered their promoters with honour, and their country with glory; but in civil engineering where more triumphs of this kind have been achieved than in any other branch, they are passed over in silence and neglect. Jenner was rewarded for introducing vaccination, Watt is crowned with praise for his improvements on the steam-engine, and the fame of Captain Cook is established on an immoveable basis; but few think of the claims of those who introduced or improved railways, locomotive engines, and suspension bridges. The last traveller who has advanced an inch nearer to the Pole, is considered worthy of higher honours than those who have given to all generations immortal testimonies of their own genius, and their country's greatness. Every new work adds some farther improvement to the science; and notwithstanding the heavy responsibility which weighs upon engineers, the boldest experiments are being continually made at the hazard of their own fame, with small chance of reward, and often with a lowering prospect of doubtful success. The bold attempts on the Thames Tunnel, and the Great Western Railway, are noble efforts of the enterprise of the engineers, and of the public spirit of their countrymen. The author may suppress an unworthy composition, the artist may discontinue an unsuccessful work, and the philosopher may renew experiments which he is praised for having attempted; but the plan of the engineer once commenced, to pause is to be disgraced, and to commit an irreparable error, is ruin in the eyes of the world and of all posterity. Young men who are entering the profession may feel assured that unless they have a natural genius for it, they will fail, even should they acquire the most extensive mechanical and scientific attainments; and they will as certainly turn out plodding surveyors or mere clerks of the works, as one who enters on some other career without proper taste will become a scribbler or a dauber, a briefless barrister, or an unfeed physician. They must remember that this is a profession which has to combat the difficulties of streams, tides and currents; to work under the surface of the ground, to soar over the valley, and to pierce the hidden recesses of the mountain; to stem the sea with a bridge, and to erect buttresses against the tempest.

The claims of the profession to be received as one of genius being thus established, it remains to be considered what title it possesses to rank with others; and in this it will be necessary to refer to the circumstances which have previously influenced it. Among the Romans and other ancient nations, engineering was always executed by the military, and it was esteemed a glory in even the greatest commanders to preside over works to which their names were often attached. This union of the two professions was carried down to the lowest ranks; and the common soldier carried his weapons and his spade, just as the commander alternately directed a distant campaign, or an important work. Even down to our own times, some degree of connexion has always been maintained, and in the English and most other services the Artillery and Engineer departments are often employed on public works; while in Sweden in time of peace the whole army is occupied as the Romans were of old in constructing canals, bridges, and docks. In Holland and France, civil engineering forms a distinct government department; but the effect of this arrangement is to produce exactly the result of a University or an Academy,—to send forth abundance of men of instruction, but few men of genius. The profession however enjoys a high rank, and its services are properly appreciated.

In England down to a late date, the profession has existed by isolated but brilliant names, and has been little appreciated. The great impulse given by the construction of canals and railroads has increased the number of its professors, and established them as a distinct class; but much remains to be done before it can be regarded as placed in its proper rank. The formation of the Institution of Civil Engineers is a happy omen of the success of the profession; as is the foundation of classes for its study in the Universities of Durham, and London. A most important result of its progress will be to subdivide into branches, and by such subdivision of labour to improve each respective department; already the civil and practical engineers are separated, and a distinct classification for harbours, railroads and bridges will certainly promote an equally beneficial result.

In conclusion,—the successful progress of Civil Engineering is important not only to the commercial and manufacturing interests of the country, but to its perpetual welfare; and as this century is already distinguished by some of the noblest efforts of this science, so it is to be hoped that the new reign may leave to future generations many such memorials of the national grandeur, and undeniable testimonies of that true glory which seeks public utility rather than empty fame.

THE PARKS AND METROPOLITAN IMPROVEMENTS.

In our last, we gave a general review of these most valuable ventilators to our great city; and we would now say a few words on the buildings that adorn them, but that we do not feel at liberty to assume the critic on the works of *living* artists, nor wish to thrust our hands into a hornet's nest. We shall therefore only congratulate the public that in the greater part of the late erections, the principles of *Grecian* art have been followed, and its capabilities asserted, whether in adorning the less extended area of a Park Lodge or the more expanded volume of a colossal building.

But before we proceed to our subject we must advert to a criticism which has elsewhere appeared, upon our remark upon the improper use of bronze or any valuable metal for public monuments. As contradicting our position, the bronze horses over the porch of St. Mark's Venice, the equestrian statue of Marcus Aurelius at the Capitol, and the Balbus of the museum at Naples are quoted. But these three instances out of three thousand, or more probably thirty thousand, are the exceptions that confirm the rule. The Venetian horses were the pillage of Greece; to whose honour they were originally formed, is entirely unknown. They ornamented successively different triumphal arches at Rome; were transported by Constantine to his new city, and conveyed thence by the Venetians when they took and plundered Constantinople in 1206. They were removed to Paris in 1797, and restored to Venice in 1816. Whether they have finished their travels, is in the womb of time; but they do not now, nor do they ever appear to have supplied, since their removal from Greece, any memorial of their original creation.

The Marcus Aurelius was accidentally preserved, and as accidentally found in forming the area around the church of St. John Lateran; Vasi describes it "as the ONLY equestrian statue that remains of all that embellished ancient Rome." The Balbus was preserved by the same eruption that consecrated the ancient cities of Pompeii and Herculaneum to modern research.

Statues however, of such colossal dimensions as could scarcely be accidentally buried; the Apollo, which Pliny describes in the palace of the Cæsars on the Palatine, fifty feet in height; that of Nero, the work of Zenodorus, one hundred and twenty feet high; were no doubt re-cast for domestic purposes, and are probably now in the British Museum under the useful forms of jugs, saucepans, and other necessary utensils;—forming no unapt parallel to Hamlet's reflection tracing the "noble dust of Alexander stopping a beer barrel." We think we need not further enforce this argument; but the consideration of the question has led us to a new reading of the often quoted barbarism of Mummius the Roman Consul, on the taking of Corinth B.C. 147. Had the ignorance of that conqueror equalled all that has been said of him, still he would surely have learned the value the Corinthians placed upon many of their statues, which he was transporting from their city by the right of conquest, (although himself entirely unequal to their appreciation as works of art), and have estimated them accordingly. They are reported to have amounted in number to several thousands: from the known celebrity of the Corinthians for casting in metal, they may be supposed to have been chiefly of bronze; and as the greater part were probably not better than

some that have lately been set up in our own capital, Mummius having ascertained their WEIGHT (with an eye to prize-money) gave notice to the Commissariat who had the charge of the booty for the general benefit of the army, that if there was any deficiency, they were the responsible officers to make it good. But as the object in erecting monuments in public places, is to carry down to a distant posterity the expression of a nation's gratitude to its benefactors, let us for a moment consider how far this has been accomplished by the employment of bronze. In our own capital the statue of Charles I. remained on its pedestal about twenty years, and was preserved from total destruction, only by the same cupidity that had ordered its sale. In Paris the statue of Henry IV. occupied its position for nearly one hundred years (a brief immortality), ere it was fated to circulate under the useful but somewhat degrading form of pieces of two sous, having exchanged the stamp of royalty for the emblems of revolutionary France. We have no precise date of the duration of *antique* bronze statues: we only know that they have all disappeared, and may conjecture that they have followed, what may be termed the law of nature.

Let us now turn our attention to other materials—stone or marble. In our capital we have but little sculpture placed externally; but as even one small specimen is fully enough for our purpose, we will refer to the alto relievo on the base of the monumental column erected by Sir Christopher Wren in the City. It is now, after a lapse of one hundred years, although placed in the most moist and the most smoky part of the town, as perfect though not quite so clean, as when left by the sculptor; no feature has suffered either from mutilation or decay.

But although London affords us but this solitary example, how amply are we supplied by the ecclesiastical buildings of our episcopal cities! Many of these already boast an immortality of six or seven hundred years; and though the fury of the iconoclast has in some instances damaged what was within his reach, yet as no other feeling than religious enthusiasm directed him, they have escaped with only degrees of injury. As regards our own posterity then, for the next ten generations, we may safely reckon upon stone: and if we refer to other climes we are lost in the long perspective. Suffice it to say, that the Greek marbles in the British Museum speak the same language to us, that they did to the Greeks themselves three thousand years ago; and that while no one statue of bronze has reached our times, those of marble, although exposed for so many centuries to all the varieties of the seasons, have with but trifling injury been preserved for our instruction. From all example therefore we feel the truth of the assertion we now repeat, "*that all monuments intended to convey to posterity the gratitude of man to his benefactors, should be formed of a valueless material.*"

We have now to make, what will at first appear to be a somewhat *startling* digression; but we are warranted in offering our remarks by no less an authority than Vitruvius, who (l. 1. Introduction) says, speaking of the necessary qualifications of the architect; "Skill in physics enables him to ascertain the salubrity of different tracts of country, and to determine the variations of climates; for the *air* and *water* of different situations being matters of the highest importance, *no building will be healthy without attention to these points.*" The subject to which we allude and which has created great alarm for the health of our beloved Queen, is the report that Typhus fever is prevalent in the New Palace; and with such efficient cause as we shall point out, in full operation, no one will for a moment doubt that such effects *may* be produced.

The experience of the whole reign of his Majesty George III. will attest the salubrity of the spot, even before the recent and complete drainage of that part of the town, now occupied by the Belgrave Square district, and which as the "Five Fields Chelsea" was during seven or eight months of the year, little better than a morass. The Grandfather of her present Majesty resided here with his numerous and healthy family; and some cause must have effected an evil, which the change we have alluded to above, must have made even more remote. That cause may probably be found in the very extended surface of stagnant water lately introduced *on each side* of the palace; the miasma of which, inferior in *quantity* only to the malaria of the Pontine marshes, must be ever penetrating into the apartments. Whether the wind be from the East or the West (the most prevalent winds of our climate), there is no escape for the pestilential vapour, which blown directly against the palace, must insinuate itself into it and therein deposit all its noxious qualities.

But were these circumstances insufficient to convert a healthy into an unhealthy spot, there is yet a hidden but no less operative cause. At the top of Constitution hill, and near the entrance archway, concealed from public view by the low shrubbery around it, is the reservoir formed by Mr. Nash for the purpose of supplying the fountains he intended to place, but which were not executed, in the Royal Gardens. It is now neglected and probably forgotten. It is we imagine about one hundred feet in diameter; we do not know its depth, but at the time we saw it (the morning of June 8th), it was filled to within about five feet of the curb; covered with a thick coating of green animalculæ, except where the even surface was broken by the bodies of eight dead dogs; a vertical sun was acting in its full power on the putrid mass. We admit that this reads very unpleasantly and very unlike the description of the gardens of Adonis, but it is impossible to describe such things "en couleur de rose."

To remedy these evils (and the remedy may be effected during the absence of the Court for the autumn), it is only necessary to bring back the ground to the state, as far as the elements of land and water are concerned, in which it was at the time to which we have referred, namely, to draw off ENTIRELY the shallow and pestilential lake in the Palace gardens; the small depth to which any part of it is dug will give only a variety to the surface of the ground, and an opportunity for judicious planting: and to fill up the Western half of the ornamental water in the St. James's Park enclosure, and the useless reservoir on Constitution Hill. These cheap and efficient remedies will secure the health of the inhabitants, and relieve the public from the charge of erecting another palace, which will assuredly be forced upon them by the necessity of the case, should the symptoms we have quoted from several public journals, and which we imagine may be but too true, continue. May they thus avoid

"Whatever plagues
Rise from the putrid watry element,
Motionless and rank."—*Armstrong.*

To resume our more immediate subject. We have expressed our unwillingness to criticise the works of *living* artists; but we do not feel, that that principle prevents our remarking upon designs to which no professional name is attached, and we therefore assume the privilege of treating them as public property.

Nothing can exceed our regret that such should be the case:—that a building so noble in its purpose and so prominent in its position, as the new chapel for the Wellington Barracks, should not have had upon it the impress of the talent of a Smirke, a Barry, or a Cockerill. That its design has not proceeded from any of those gentlemen, the proof is afforded by the flagrant violation of some of the most fixed principles of the order in which it is erected; and for which departure from antique models we have no means of fixing a responsibility.

That upon a building upon which Pericles would have employed Ictinus or Callicrates, our modern Pericles should have thought fit to consider only the most economical method of obtaining professional assistance, and have disregarded or undervalued that fragment of Himerius which says, "so great was the effect of the Parthenon in the eyes of Greece, that its construction alone might have sufficed for the glory of Pericles;"—must be a source of great regret so long as the building shall exist, and we shall not shrink from stating wherein we think our observations are borne out.

The principal or West end has a portico of four Doric columns; but its author has most ingeniously contrived to create a difficulty to himself, where the most limited acquaintance with ancient authorities would have taught him to adopt a beauty. Instead of keeping the line of his flanks unbroken, and finishing the walls with antæ, he has reduced the width of his portico about two feet on each side, preventing thereby the use of those characteristic terminations, and almost forcing upon himself the necessity of employing clumsy pilasters,—features never used by the Greeks,—in order to appear to carry the return of his entablature. To this unnecessary deviation from right for the purpose of doing wrong, he has added the hardihood of omitting the mutules over the metopes; thereby destroying that continuity of form, so eminently desirable; and which may not unaptly be likened to drawing each alternate tooth from the mouth of a beauty. But if the entrance front thus displays either an ignorance or a vanity of alteration so inimical to the effect of the building, how much greater a departure from all rule do the flanks exhibit. That maxim of the Greeks, (even more religiously observed by the Romans),—that the metopes should be a square, or so nearly so that the eye cannot perceive a deviation from that figure,—is entirely departed from, and the frieze exhibits the extraordinary appearance of metopes of three varied sizes on the same line. The author had here only to preserve the straight line of wall and to perforate it for windows; but this simplicity was beyond him, and he has again recurred to the unknown pilaster, at once destructive of all character and subversive of all rule.

We have before said that the details of the design are convincing proofs that it has not proceeded from any high professional character: and our zeal for the profession carries us somewhat further; namely, to the very reasonable inquiry, why the defects of some later professors should be employed as a pretext for depriving the profession of the rank of Surveyor General, formerly held by Sir William Chambers

with so much credit to himself and so much benefit to the public. It may be conceded, that the situation, from the examples to which we have alluded, might have required some control over its expenditure; but that the rank which gave the head of the profession the power of direct communication with the Sovereign, should have been lost, must be felt in every grade of it, and should stimulate all its members to its recovery. If the architectural members of the Royal Academy, the Architectural Society and the Institute of British Architects, do not endeavour to accomplish this object;—if they do not set forth the claims of the profession to a more prominent situation than that of occasional consulting counsel, when the difficulty appears too great for the office clerks;—they may as well dissolve their associations. They may flatter themselves, that they are encouraging good taste, they may hope they are aiding the education of men who may do their country honour, but they will find they are exerting themselves to no good purpose, so long as their care is nullified by the employ of of irresponsible or incompetent parties.

We are fully convinced too, that by these deviations from established forms, an unnecessary expense has been incurred, which would have paid the commission of an educated and intelligent architect, and saved at the same time the character and the purse of his employers. The deviations may appear trifling to the unprofessional reader, and the circumstance of the building answering its purpose be triumphantly asserted; but we beg to explain our position by analogy with the art of poetry, which our highly born and highly educated ministers *will* appreciate. Would they tolerate a false quantity in a Greek or Latin hexameter line,—or consider as sufficient the excuse, that it conveyed the sense of the passage,—or would they admit him to the rank of a poet—

> "Who free from rhyme or reason, rule or check,
> Breaks Priscian's head and Pegasus's neck."—*Pope*.

We now again ascend the steps at the foot of the York column, and pass, on the principle we have before mentioned, the buildings that surround us. Turning our eye Eastward, we are caught by the view of the National Gallery; and in the same direction, we observe the spire of St. Martin's Church, rising above the mass of houses that have been recently built: and our regrets must find utterance, that in the first consideration of the improvements in this quarter it was not made a peremptory command, that the fine portico of that church should have terminated the vista of Pall Mall. This principle neglected, all else has been confusion and compromise.

We ought however, as in much else in our mundane state, to rejoice that we have escaped so well; and as we consider that a criticism on the National Gallery will be no departure from our principle, we are induced to give that building our next consideration. We consider it no departure from our principle; because Mr. Wilkins is understood to have retired from the practical exercise of his profession, and his fame is therefore public property. That fame will require no blazon from us; the integrity, taste, and science which he has brought into his professional practice are evinced in so many ways and always so much to his honour, that we look to his long enjoyment of his retreat with equal hope and pleasure.

For we are far from being of the number who venture unmeaning and undefined censure on the National Gallery, and we are sure that even the errors which those people decry, are not attributable to the professor. Among the most prominent is the want of height. But the cavillers should be aware that two very sufficient causes prevented a greater altitude;—namely, limited funds, and the necessity imposed on the architect to employ the old columns from Carlton House. To use these without effect, Mr. Wilkins has placed them on a high basement and contrived to convert the want of space in his front into a great beauty;—we mean the approach by the side stairs, which create a picturesque effect from the groups passing up and down, (and particularly on the side view,) which no other arrangement could effect; and we always regret that the Royal Academy, apparently for the purpose of coaxing a few shillings on a wet day, should have disfigured their side of the building with a permanent covering. Having obtained this base, the architect had to place thereon his vagrant columns; and this circumstance added to the desire of not swelling his pecuniary charge beyond the wishes of the government, decided the height now condemned.

We shall return to this question after saying a few words on the other objection; the too numerous breakings of the front. Here again that irresponsible interference must bear the blame. It is well known that the columns on the side entrances formed no part of the original design, but were added on a suggestion that could not be disputed, in the idea of masking what they have served (besides their other demerits) only to make more remarkable, and to effect which, eight new columns were made to match the old ones.

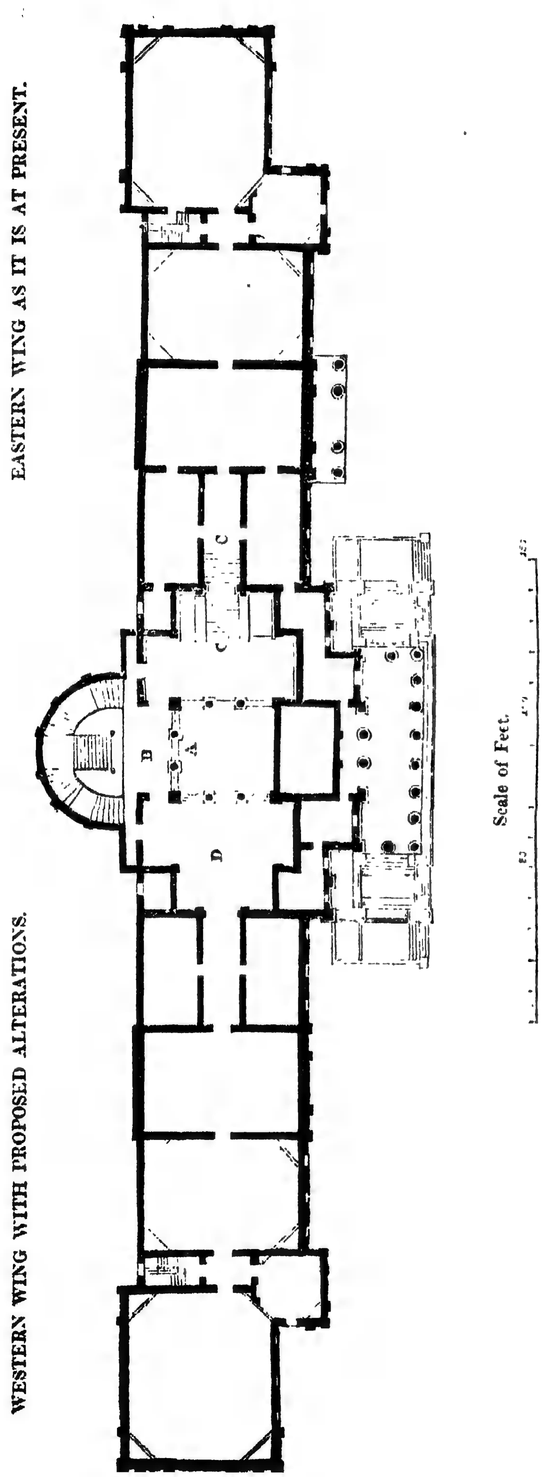
In order that we may dismiss this portion of our subject while the elevation is under consideration, we will venture to call to the mind's eye what it would have been without this interference, and with a small addition to the contemplated expenditure. Of these alterations the most effective would be the removal of the side columns. If the abstraction be desirable as giving repose to the front when seen from the south, how much more effectual will it be, for the improvement of the building, when seen from Pall Mall or Duncannon-street! From those points the numerous angles and breaks are truly distressing. This alteration would create but a very trifling expense, and the government would still be in possession of eight columns wherewith to task the ingenuity of some future state-architect. On the removal of the open ballustrade and the formation of a solid and somewhat more lofty attic, and the addition of a range of columns round the drum of the dome, a small expense might be incurred; but with these additions and subtractions, which we fully believe the architect contemplated, we do not hesitate to say that the building will be equally the admiration of the present day and of posterity. We never pass up Whitehall but we rejoice to see how nobly the portico fills the spot, and until we catch a sight of the side columns we are enchanted with the rich simplicity. In this view we know that we are supported by the first non professional opinion of the day on architecture and sculpture.

Our next consideration is the interior arrangement. There we at once combat the senseless cry of "Where is the gallery?" All the world has been to Paris, and all the world has walked through the Louvre; and therefore our National Gallery is to be assimilated to that very inconvenient expectation. No doubt they are somewhat led astray by the term "gallery;" although with us that term has lately been applied to every collection of art, and as in the instances of the Stafford, the Grosvenor, the late receptacle for the National, and other collections, has nothing to do with the dimensions or shape of the apartment in which they are exhibited;—the word "gallery" in that sense describing a collection of art. We know no rooms where the pictures are better seen, where by the cross divisions more *quiet* is secured to the parties who are enjoying the contemplation of them: and our only regret is, that in the wish to cover as much wall as possible or for some other cause, pictures by modern artists have been admitted, the merit of which by no means establishes the right to such positions.

With these observations on a disappointment which many of the journals have loudly stated, we proceed to the general arrangement; to the task of pointing out wherein the difficulty of the architect has been increased by the discordant office to which the building is appropriated; and we shall then propose a remedy and exhibit a plan which we have well considered and therefore fearlessly recommend. The building is equally divided between the National collection of pictures, and the Royal Academy. To obtain for the latter a place of exhibition for sculpture, it was necessary to form a room on a lower floor and easily accessible from the street. This, the architect has effected, but to the great detriment of his principal entrance; which is dark, and the approach to the principal floor indirect. And not only was his purpose of making his stairs a prominent and visible object, immediately on entering the building, foiled by this necessity; it has created another and not less serious evil, namely the narrow passage which encloses the stairs leading to the principal rooms. These are the only objections that force themselves upon us, and we think they belong not to the professor, but to the instructions he was bound to carry out.

It may be as well here to inquire whether by the arrangements which have thus tended to mar the National Gallery, the Royal Academy has obtained what it wanted in space for the purposes of its institution; and if on a candid inquiry it shall appear that the art has gained nothing by the change, while the public has been a great loser, we hope the plan we shall propose for satisfying all parties, will be entertained with the same good feeling with which it is proposed. It will be admitted that there could be no more cogent reason for moving the Royal Academy from Somerset House, than the desire to procure more accommodation for the student: the institution being, not a sinecure for the professors, but a *Royal Academy of the Fine Arts*. It is not however generally known, although it cannot be too earnestly considered, that the academical year may be stated to commence on the 1st of October; that the schools are open during the dull and cloudy season of the year, when in the day time there is little light, and in the evening the severity of the weather often prevents attendance, and close *in the first week of April until the end of July*. They are again open for the month of August, and close on the 1st of September. By this analysis it will be seen, that during all the time the student could emply himself beneficially, he is turned adrift for the purposes of the annual exhibition; and that he is

PLAN OF THE PRINCIPAL FLOOR OF THE NATIONAL GALLERY.



at full liberty to attend, when it is most likely he cannot see what he is about. The party therefore whose interests ought to have been consulted has been neglected; nor does any other party appear to have proportionally gained. We have therefore to propose *another move*; and we should not do so, had we not the opportunity of introducing the establishment to a locality in every respect more eligible. It is understood that Burlington House in Piccadilly might be purchased; and we would most respectfully recommend to the government to make that valuable purchase, of a freehold which would long since have been sacrificed to the interests of speculating builders, had not the noble owners retained the high sentiments of the cultivated mind that originally erected it. In possession of this space, galleries might be erected on the North at a very moderate cost, sufficient for the annual exhibition; and the students might thus be accommodated *all the year round*. The government would likewise obtain space for locating under the same roof and its wings, the Royal, Antiquarian, Astronomical, and other scientific societies, which now occupy apartments in Somerset House; and thereby be enabled to accommodate the business offices of the State in that central situation. Our neighbours would designate the new locality as "Hotel des Arts et Sciences;" we should feel that the arts and sciences could not be more appropriately placed than in Burlington House.

Having performed our promise of placing the Royal Academy more advantageously, we have now only to deal with the exhibition of the National Collection of Pictures; and to the better understanding of the mode in which we would propose to do this, we refer to the plan, one half of which exhibits the Eastern wing as it is at present, and the other the Western wing with the alterations we propose. The circular projection, now forming the exhibition room for sculpture, we would occupy by the staircase giving access to each wing. The middle wall at A, is replaced by columns, as on the sides; a flood of light is thereby introduced into the centre saloon, and the approach to the upper floor made immediate and evident. Besides the architectural effect which would result from these alterations, the great test of good design—fitness—would thereby be obtained, by the removal of the great inconvenience, consequent upon retaining the present stairs, — (should the building form one establishment) — namely that of passing down one set of stairs to mount another. The gallery of communication B would remedy this; and the staircases C C being removed, the whole area of the room D would be added to the uses of the building. The central saloon would as at present occupy two stories in height, and the vista of the whole length of the building on the principal floor be preserved.

Gradually covering the walls with specimens of ancient or modern art, as such examples should be acquired after a most critical examination of their merits;—and admitting none, as our continental neighbours have undoubtedly done in some instances, merely to cover the walls;—we should be long so employed ere more space were required, And that space is readily obtainable at any time by an encroachment, or the entire appropriation of the barrack yard in the rear;—a resource which no doubt the government had in view when they made so noble an appropriation of the ground to its present exalted purposes.

We might fairly presume that we should then attain that excellence in art, which alone has served to keep alive the remembrance of nations; but we are thereby to accomplish a more valuable object, for "the great use of the arts, is to humanize, refine and purify enjoyment, and to connect the perception of physical beauty with moral excellence."—*Addison*. J. H.

DESIGNS FOR POOR-HOUSES.

The various Boards of Guardians of the Poor in Devon and Cornwall, are constantly advertising to "architects" for designs for poor-houses; and although none of those gentlemen who would be recognised *as* "architects" by the British Institute ever think of answering them, there is no lack of unemployed masons and *designing* builders in readiness to send in plans. We understand however that the "cheap and nasty" system is bringing a return of due ridicule upon the sapient mismanagers of the yet unfinished buildings; and that the regular architects who were scouted as unnecessary for the preparation of fitting plans and specifications, are being busily employed in putting to rights the blunders of those who have been most unwisely and unjustly allowed to "push them from their stools." A. B.

American Oven.—A new domestic oven, of American invention, was lately exhibited to us. It is somewhat similar in form and construction to the well-known Bachelor's Oven, and is used in exactly the same way. The chief difference between the two consists in the present one being square, while the Bachelor's oven is nearly triangular; and in the former having the tray or pan for holding the meat considerably elevated, that the heat may enter below. The great advantage of this is, that it always allows the rays of heat collected upon the surface of the white iron, to be reflected upon the meat, above and below; thus rendering the invention one of the readiest means of dispatch in the way of cooking which a family can possess. It is so simple, so useful, and so cheap, that it only requires to be known, to be in as common demand here as in America, where we believe it is in general use.—*Scotsman*.

ON HYDRAULIC AND COMMON MORTARS. BY GENERAL TREUSSART, INSPECTEUR DU GENIE.

[Translated from the French by J. G. Totten, Lieut.-Col. of Eng. and Brevet-Col. United States Army, for the *Franklin Journal.*]

Art. 1.—*On the present state of our knowledge of Lime.**

Lime has been employed from time immemorial. Mixed with sand, or certain other substances, it forms what is called mortar. Although the solidity and durability of masonry depends on the goodness of mortar, still few experiments have been made with lime, and the manner of making mortar has almost always been given up to workmen. It is only within about fifty years that a few scientific men have attended to this important subject. Comparing the mortars of the ancients, and especially of the Romans, with those of modern times, it was perceived that the old mortars were much better than ours; and the means have, consequently, been sought of imitating them. Several constructors have thought they had discovered the secret of making Roman mortars; others, on the contrary, have thought that the Romans had no particular process, but that, of all their constructions, those only which were made of good lime had survived to our day. We shall see that my experiments tend to confirm this latter opinion.

Lime used in building, is obtained by the calcination of calcareous stones, which occur abundantly on the surface of the globe. Marbles, certain building stones, chalk, calcareous alabaster, and shells, are employed in making lime. The effect of calcination is to drive off the water and the carbonic acid, which are combined with the lime. The water and the first portions of carbonic acid pass off easily; but it requires an intense and long continued heat to dispel the remainder of the acid. Lime, as used in constructions, contains, almost always, a considerable quantity of carbonic acid.

When the stone submitted to calcination is white marble, pure lime is obtained, provided the calcination be carried far enough. According to an analysis which I made of white marble, this substance contained, in 100 parts, as follows: lime 64, carbonic acid 33, water 3. Lime obtained by calcination possesses the following properties. It has a great avidity for water, imbibes it from the air, and has its bulk enlarged thereby. If a certain quantity of water be thrown on lime recently calcined, it heats highly, breaks in pieces with noise, and a part of the water is evaporated by the heat produced. The disengaged vapour carries off some particles of lime. Water dissolves about one four-hundredth of its weight of lime, forming what is called lime-water.† Lime is caustic and turns the syrup of violets green; its specific gravity, according to Kirwan, is 2. 3, it attracts carbonic acid from the air, and finally returns to the state of carbonate of lime. To preserve it, it is necessary to keep it in very tight vessels.

Lime was formerly ranked among the alkalis, and it is only lately that the true nature of the substance became known. Davy, the English chemist, succeeded in 1807, in decomposing, by means of Volta's pile, the sulphate, and the carbonate of lime, or more properly *lime* derived from these compounds; obtaining a brilliant substance, having so strong an attraction for oxygen that it absorbs it rapidly from the air, and from water, which it decomposes. The brilliant substance obtained from lime is regarded as a metal, and has received the name of Calcium. Accordingly, lime is only a metallic oxide.

It is rarely that lime derived from white marble is used in the arts; that which is commonly employed, and which is derived from ordinary limestone, almost always contains oxide of iron, and sometimes a certain quantity of sand, alumine, magnesia, oxide of manganese, &c. Some of these substances combine with the lime by calcination; and the lime thus acquires properties which it had not before, and of which I shall speak in the sequel.

If we take lime derived from white marble, or from common lime stone, and reduce it as it comes from the kiln to a paste with water, and if we place this paste in water, or in humid earth, it will remain soft for ever. The same result will be obtained if lime be mixed with common sand, and the resulting mortar be placed in similar situations.

It is a common practice to deluge lime fresh from the kiln, with a large quantity of water, and run it into large basins, where it is allowed to remain in the condition of soft paste. Alberti says (book II., chap. XI.) he has "seen lime in an old ditch that has been abandoned about 500 years, as was conjectured from several manifest indications, which was still so moist, well-tempered, and ripe, that not honey or the marrow of animals could be more so."

There is another kind of lime which possesses a singular property; if it be slaked as it comes from the kiln, as above, and be then placed in the state of paste, in water or in moist earth, it will harden more or less promptly, according to the substances it contains. The same result is obtained if the lime, being mixed with sand, is made into mortar and placed in similar situations. If this lime be slaked and run into vats, as is done with common lime, it will become hard after a little time, and it will then be impossible to make use of it.

On slaking lime, fresh from the kiln, with enough water to reduce it to paste, it is found to augment considerably in bulk; this augmentation is such, that one volume of quick lime will sometimes yield more than three volumes, measured in the condition of thick paste. When lime which has the property of hardening in water is slaked in the same manner, it affords a much smaller volume than common lime. Sometimes one volume of this lime, measured before slaking, will give, when slaked to thick paste, scarcely an equal bulk. For a long time those limes which had the property of hardening in water were called *meagre limes*, and those which had not this property were called *fat limes*. These denominations were affixed because the first kind increased but little in bulk when made into paste, while the other gave a considerable augmentation of volume; and because fat limes formed, with the same quantity of sand, a mortar much fatter or more unctuous than meagre lime. But the designation "*meagre lime*" is altogether improper to indicate limes which enjoy the property of hardening in water, because there are limes which augment their volume very little, on being made into paste, and at the same time possess no hydraulic property. Belidor gave the name of *beton* to lime which had the quality of hardening in water; but many engineers continued to call it *meagre lime*. The denomination of *beton* is not suitable; and, in this sense, is not now in use. The following are the terms now employed.

In England, the name of *aquatic lime* has been given to lime which indurates in water; in Germany it is called *lime for the water*; M. Vicat, engineer of roads and bridges, has proposed the name of *hydraulic lime*, and this denomination, which is a very good one, has been generally adopted. I shall therefore call that lime which swells considerably in slaking, *fat lime*; that which swells but little and does not harden in water, *meagre lime*; and that which possesses the property of hardening in water, *hydraulic lime*. *Fat lime* is often called *common lime*, also. The term *quick lime* is applied to all unslaked limes, whether *fat lime*, *meagre lime*, or *hydraulic lime*. Although *meagre lime* and *hydraulic lime* may have been calcined exactly to the proper degree, still they are slower to slake, and give out less heat than *fat lime*. When *fat lime* has been too much burned, it also becomes slow to slake; while, if properly burned, it begins to slake the instant water is thrown on. Experiments, to be given in the sequel, will show that iron, in the state of red oxide, causes *fat lime* to slake sluggishly.

Some of the ablest chemists have, at different times, sought to detect the substances which impart to lime the property of indurating under water.

Bergman, a Swedish chemist, was, I think, the first who gave an analysis of a hydraulic limestone. That from Léna, in Sweden, he found to contain, in 100 parts, the following substances: lime, 90; oxide of manganese, 6; clay, 4. Bergman seems to have attributed the peculiar property of hydraulic lime, to the oxide of manganese; and this opinion prevailed for a long time. On the other hand we find in the *Bibliothèque Britannique*, of 1776, vol. 3, page 202, that Smeaton the English engineer, who built the Eddystone Lighthouse in 1757, attributed this property to clay; for he says that it is a curious question, which he leaves to chemists and philosophers to decide, why the presence of clay in the tissue of a calcareous stone should give it the property of hardening in water, while clay added to common lime produces no such effects.

Guyton de Morveau, announced in a memoir published in 1809, that he had detected the presence of oxide of maganese in all the limestones which afforded hydraulic limes; he announced further, that in calcining together 90 parts of common limestone pulverized, 4 parts of clay, and 6 parts of black oxide of manganese, an excellent artificial *meagre lime* would be obtained. It was stated above, that at that time the name *meagre lime* was given to lime that would set under water; the French chemist was the first, therefore, to make artificial hydraulic lime; but he, as well as Bergman, was mistaken in supposing that the presence of the oxide of manganese was necessary to the result. He would have obtained his result by burning the pulverized limestone with clay alone.

* The present article is the first of a series on hydraulic and common mortars. In presenting them, the Translator thinks that he is rendering a service to the art of construction in this country.

The French, within a few years, have devoted themselves with great zeal and effect to the subject of mortars; and they have applied, with perfect success, the results of their experimental investigations to actual constructions of great difficulty and importance. The English are, perhaps, equal to the French in knowledge of the best constituents of mortars, and in the practical composition and use of them; but they are not, like their neighbours, in the habit of recording, methodizing, and publishing their experience; and hence, though important information may be very generally spread among their builders of all classes, it is nowhere to be found concentrated in books.

In this country we have been led, within a few years, to some improvements in the practice of mortar making, by the actual necessity imposed by extensive hydraulic works, and by the providential diffusion over our territory of an admirable material; still we are, for the greater part, the slaves of an antiquated routine, elsewhere known to be radically wrong.

The works here translated are recent, and amongst the best issued from the French press: others have been carefully consulted; as Vicat's, Raucourts's, Soleirol's, &c., but these have been preferred as answering best to our need.* To most American readers, they will present many new results, highly important, and of a character to be applied with great advantage to our own operations; they are, therefore, commended to the perusal of all who have an interest in the subject.

In relation to the terms employed in translation, it is proper to state that the expression *fat lime*, used for the *chaux grasses* of the French, is applied to lime nearly or quite pure, not hydraulic, and which swells much in slaking. *Poor lime*, or *meagre lime*, substituted for *chaux maigres*, means a lime which slakes reluctantly, swells but little, and is not hydraulic. *Hydraulic lime*, *chaux hydrauliques*, implies a lime which will harden, in a longer or shorter time, under water: this generally slakes slowly, and swells but little. The French term *ciment* means, almost always, finely pounded bricks or tiles: with us, *cement* is a sort of generic term, having various significations, but generally implying, when used herein, the hydraulic constituent of mortars.

The term *puzzalona* belongs, strictly, to a peculiar volcanic product, formerly much used in hydraulic mortars, and which is particularly referred to herein; it is, however, often used to signify natural substances not volcanic, and even artificial substances, if producing effects similar to those afforded by the real *puzzalona*.

The English having adopted the expressive term *concrete*, to signify the mixture called by the French *beton*, the same term will be used in this translation.

† One four hundredth, Davy—one seven hundred and fifty-eighth, Thompson—one seven hundred and seventy-eighth, at 60 deg. Fahr., Dalton.—Tr.

M. Saussure, in his *Voyage des Alpes*, says that the property possessed by certain limes of hardening in water is due solely to silex and alumine (that is to say, to clay) combined in certain proportions.

M. Vitalis, chemist, of Rouen, made in 1807, the analysis of the limestones of Senonches and St. Catherines, near Rouen; the analysis is contained in the memoir on the schists of Cherbourg (page 58), published in 1807, by M. Gratien, sen., engineer of roads and bridges. This limestone contains, according to M. Vitalis, in 100 parts, the following substances; water, 12; carbonate of lime, 68; alumine, 12; sand, 6; oxide of iron, 2. In addressing these results to M. Gratien, sen., M. Vitalis expresses himself thus:—"It follows from the analysis that the limestones of Senonches and St. Catherines, are two calcareous marles, in which the chalk predominates it is true, but wherein the clay performs an important part. It is this portion of clay which, in my opinion, makes the lime of these two limestones *meagre;* whence it follows, that the presence of oxide of manganese is not indispensable to the constitution of such limes, since the analysis proves that the limestone in question contains no oxide of manganese, as it would, if present, have coloured the glass violet." I noticed above that these hydraulic limes were then called *meagre limes*. We see that the analysis of these stones confirms the opinion of M. Saussure, who had attributed to the clay alone the property of hardening in water. Thompson, an English chemist, was of the same opinion.

M. Descotils, engineer of mines, also made an analysis of the limestone of Senonches; which analysis may be found in the "Journal des Mines," of 1813, page 308. According to this trial, the Senonches limestone contains a quarter part of silex, disseminated in very fine particles, and only so small a quantity of iron and alumine, that these substances can have no influence on the lime; whence this engineer concludes that the hydraulic property of this limestone is owing to the silex. We have, however, seen above, that according to M. Vitalis, it contains twice as much alumine as silex. M. Berthier also inserted in the "Journal des Mines," an analysis of the Senonches limestone, which will be given further on, and according to which the stone contains very little alumine. This contradiction has not yet been explained. Perhaps the quarries at that place afford stones of different kinds. If so, it would be important to ascertain what is the composition of the best.

The analysis of the Senonches limestone afforded M. Descotils occasion to make an important remark on the silex contained in limestone; namely, that the silex found in these stones does not dissolve in acids before calcination, but does dissolve after calcination. This fact proves that the properties of silex are changed by calcination with lime, and that it combines in the dry way with this substance.

M. Vicat, engineer of roads and bridges, published, 1818, a very important memoir on hydraulic mortars. This engineer set out with the opinon generally admitted at that time, that it was the clay which gave to lime the singular property of hardening in water. He, in consequence, took fat lime, which he mixed with various proportions of clay, according to the following process, extracted from page 7. "The operation we are about to describe (says M. Vicat) is a true synthesis, reuniting, in an intimate manner, by the action of fire, the essential principles which are separated from hydraulic lime, by analysis. It consists in allowing the lime, which is to be improved, to fall spontaneously to powder in a dry covered place; afterwards to mix it, by the help of a little water, with a certain quantity of grey or brown clay, or simply with brick earth, and to make balls of this paste, which, after drying, are to be burned to the proper degree.

"Being master of the proportions, we may conceive that the factitious lime may receive any degree of energy desired, equal to, or surpassing at pleasure, the best natural lime.

"Very fat common lime will bear 0.20 of clay to 1.00 of lime; moderately fat lime will have enough clay with 0.15; and 0.10, or even 0.06 of clay will suffice for those limes, which are already somewhat hydraulic. When the proportion is forced to 0.33 or 0.40, the lime does not slake, but it pulverizes easily, and gives, when tempered, a paste which hardens under water very promptly."

Such is the process indicated by M. Vicat. But this engineer did not content himself with experiments on a small scale: a manufactory was established near Paris by his means, where artificial hydraulic lime is made in large quantities; he moreover exerted himself to extend the use of hydraulic mortar everywhere, and he succeeded. He has, therefore, rendered an important service to the art of construction, and I have done him the justice to make this acknowledgment, in the notices I have heretofore published.

In 1818, Dr. John, of Berlin, presented to the Society of Sciences, in Holland, a memoir, which was published in 1819. This memoir, crowned in 1818 by the Society, answered the following question proposed by the Society:—"What is the chemical cause, in virtue whereof stone lime makes generally more solid and durable masonry, than shell lime, and what are the means of improving shell lime in this respect?" Dr. John has remarked, that shells require to be more highly calcined than common limestone: he thinks this owing to the shells being purer carbonate of lime than common limestone, which contains earthy substances, facilitating the disengagement of the carbonic acid. In making the analysis of sundry limestones, he found that those which afforded hydraulic lime contained clay, oxide of iron, &c. He called the foreign matters which gave the property of hardening in water, *cements;* and says, that it is possible, by introducing cement in the dry way, to ameliorate lime which contains none. On these considerations he made the following experiments:—He mixed the powder of oyster-shells, first with $\frac{1}{18}$ of silicious sand; secondly, with several proportions of clay, varying from $\frac{1}{10}$ to $\frac{1}{5}$; thirdly, with $\frac{1}{10}$ of oxide of manganese. He tempered these mixtures by water, formed them into balls, let them dry in the air, and then burned them in a lime-kiln for 95 hours. The following results were obtained: the first mixture was agglutinated, but friable, and was not a good result; the second mixture gave good results; and the third possessed no peculiar property. The author concludes that clay is the ingredient which gives to common lime the property of hardening in water; and he says that nothing can be easier than to procure good hydraulic lime, either from shells or from pure limestone, following the process indicated: he adds, that it is for constructors to determine the best mixture to be made in each case.

The memoir by Dr. John contains the analysis of several ancient mortars, and offers several important observations, of which I shall have occasion to speak.

In the third number of the "Annales des Mines" of 1822, there is a very interesting memoir by M. Berthier, Ingénieur en Chef des Mines; it contains the analysis of different limestones, and several new views, which will contribute to form a more perfect theory of mortars. I shall have more than one occasion to cite his experiments, and his opinion on several important facts.

M. Raucourt, engineer of roads and bridges, published at St. Petersburgh, in 1822, a work wherein he narrates the experiments he made, following the process used by M. Vicat, and adding several of his own. M. Bergère, Chef du Bataillon du Génie, gave an analyis of this work in the "Annales des Mines" of 1824, Vol. IX.

In 1825, M. Hassenfratz published a memoir on mortars. This work, which is voluminous, contains many practical details on the calcination of limestone in different countries, and exhibits the actual state of knowledge in the art of making mortars at the period of publication.

In terminating this reference to works on hydraulic mortars, which have appeared up to this time, I must introduce a fact, entirely new, announced by M. Girard de Caudemberg, engineer of roads and bridges, in a notice published by him in 1827. He states, that the proprietors of mills on the river Isle, in the department of the Gironde, discovered by accident a kind of fossil sand, to which they gave the name of *arène*, which has the singular property, without any preparation, of forming, with fat lime, a mortar that hardens under water, and has great durability. I shall have occasion to return to this important fact, and to report what M. Girard says, as well as to state the principal experiments which have been made with this substance in other places where it has been found.

I was employed, from 1816 to 1825, at Strasburg, at which place they had made no use of hydraulic lime. I ascertained, however, that such lime was to be found in the neighbourhood. Almost all the hydraulic works connected with the fortifications of the place having been badly constructed, and dating as far back as Vauban's time, were to be rebuilt. Twenty-five years' experience had taught me the great superiority of hydraulic mortars in the air as well as in the water—where, indeed, they are indispensable. I tried, therefore, the hydraulic limes afforded by the environs of Strasburg, and found them excellent; they were consequently used in all the works, both in air and water. All the revetments built from Port de Pierre to Port Royal, having a development of about 1,650 yards, were rebuilt or repaired with hydraulic mortar. It was the same with the hydraulic works; they were rebuilt or repaired with the hydraulic lime of the neighbourhood.

An engineer who should use fat lime, even for constructions in the air, when there are hydraulic limes at hand, would be very censurable, because the expense is about the same; and, as regards the strength and durability of masonry, there is a vast difference in favour of the hydraulic mortar. But in countries where no hydraulic lime is to be had, or only that of mediocre quality, what should be done? Shall the engineer adopt the process of M. Vicat, which consists in making an artificial hydraulic lime? I answer, emphatically, that I think not; in this case, occurring very often, it is, in my opinion, preferable to make hydraulic mortar by a more direct process, which I shall point out.

There are two modes of obtaining hydraulic mortar: the first consists in mixing natural or artificial hydraulic lime with sand; the second consists in mixing ordinary fat lime with certain substances, such as puzzalona, trass, certain coal-ashes, and brick-dust or tile-dust. I feel bound to correct here an assertion touching these mortars, not perfectly accurate, of M. Gauthey, Inspector of Roads and Bridges. In his excellent "Treatise on the Construction of Bridges," this engineer says (vol. ii., page 278), that "fat lime is very proper for constructions out of water, but will not answer in the composition of betons to be placed in water, because the mortars in which it is used, even when mixed with puzzalona, and placed in water as soon as made, do not harden, but remain pulverulent." This is far from exact; because mortar composed of fat lime and puzzalona hardens very soon in water, and acquires, in a short time, very great strength. This fact was known to the ancients, for Vitruvius speaks of it, as will be seen further on.

I should not refer to the error into which M. Gauthey has fallen in this instance, if he did not enjoy a reputation so justly elevated. His highly esteemed work being in the hands of every engineer, it was to be feared that this remark of his would prevent constructors from making hydraulic mortars by the direct union of common lime and substances analogous to puzzalona. My experiments will show that, in countries where hydraulic lime is not to be had, instead of following the process of M. Vicat, it is preferable to make hydraulic mortar by a direct mixture of fat lime with substances of a similar nature to puzzalona. These experiments show, also, that fat lime is far from being always proper for construction out of water, although M. Gauthey, in the beginning of the sentence, states it to be.

NEW GATES AND PADDLE AT BRADLEY LOCK ON THE SANKEY CANAL.

N. B. Similar Letters refer to similar things in the Plan, Elevation and Section.

SIR,—According to your request, I forward for insertion in your Journal drawings and particulars of the new lock gate and paddles mentioned in my letter of Nov. 10th, 1837, on page 44 of your journal. I am sorry I could not forward it sooner.

The paddles have now been in use more than six months; they are no worse for wear, and remain quite water-proof. During the severe frosty weather, they worked admirably well; much better than any others on the canal.

My objects in constructing this paddle were;—to *prevent the flatmen* from wasting water by *flushing*;—to increase the facility of passing flats through the lock, by *filling it sooner*;—and *diminish* the unusual expenditure in repairs;—all of which are fully realized. Besides, the construction and placing of the hand-rail and foot-plank have greatly diminished the danger in passing over the gates, and the rail and paddle gearing are quite out of the way of the ropes and sails, there being nothing for them to become entangled with.

The idea of this paddle first occurred to my mind on the 16th November 1836, while calculating the power of some old paddle gearing; and I committed the particulars to paper on the 22nd of the same month.

Perhaps the following will be acceptable as elucidating the drawings:—

Radius of handling	18	inches.	
Do. of driver or pinion	2	,,	10 teeth or leaves.
Do. of wheel	8	,,	40 teeth.
Do. of chain groove to the centre of the chain	$2\frac{1}{2}$	,,	

And supposing a power of 60 lb. applied to the handling, the effect is as follows:—

$\frac{18\times60}{2} = 540$ lb., effect on the wheel; then $\frac{8\times540}{2.5} = 1728$ lb. effect on the chain: and by passing the chain under the sheeve at H, and suspending it to the top bar of the gate at K, thus converting the sheeve into a moveable pulley, we double the effect, $1728\times2=3456$ lb.,—which is amply sufficient for the purpose; the total resistance to be overcome being about 3000 lb.

I need not repeat what I stated in my former letter, only that the lock fills in 54 seconds; in which time not less than 6740 cubic feet=188 tons, or $46,243\frac{3}{4}$ gallons of water have passed through the paddles. I was informed the other day that several gentlemen (supposed to be engineers) had been to examine the paddles at the old double lock, which are similar to these; but it does not appear that they expressed any opinion. Should I trouble you again with any future communication, I hope it will be something of more importance; in the mean time I would state that I have a scheme for a side paddle (that is, one to fix in the masonry); which I purpose committing to paper soon. It will counteract the resistance of hydraulic pressure, and I expect that the paddle will be capable of being opened by one man, or even one boy, without the application of any mechanical power.

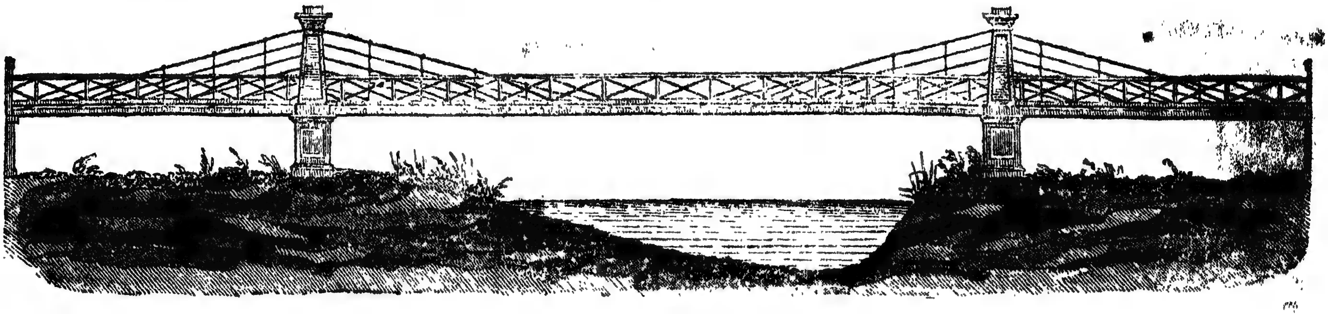
Yours, &c.,

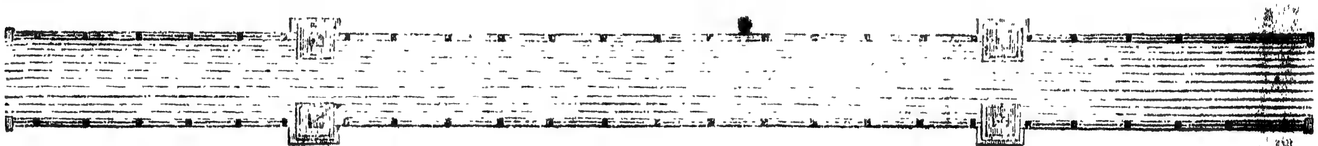
JOHN LISTER.

Engineers' Office, Winwick Quay,
May 23rd, 1838.

TWERTON BRIDGE OVER THE RIVER AVON, NEAR BATH.

ERECTED 1837: THOMAS MOTLEY, ENGINEER.





Scale of Feet.

10 0 50 100 150

THE bridge of which the above is a representation, is erected over the river Avon at Twerton near Bath, and is the first of the kind ever constructed. The span of the middle compartment is 120 ft. from centre to centre of the pyramids; the land ends are about 55 ft. each; making the whole length of the bridge 230 ft. The road-way is 14 ft. wide between the suspending bars.

The four pyramids are placed, each pair on a foundation of concrete 12 ft. by 22; 16 feet thick on one side and 9 feet on the other: the concrete rests on a firm stratum of clay. They are each composed of six courses of Bath stone 2 ft. 6 in. deep, containing two blocks in each course. Their dimensions are, base 5 ft. 6 in. by 4 ft. 6 in.: top, 3 ft. by 2 ft. 6 in. They are covered with a capping as shown in the drawing. At the base of each pyramid, level with the lower part of the beam of the bridge, is a large cast-iron bed, secured by holding-down-bolts inserted into other cast-iron plates in the foundation. In the centre of the large plate is inserted an iron bar 3 in. by 1 in., which passes up the centre of the pyramid to a cast-iron plate at the top, to which it is firmly secured.

The suspending bars are 2 ft. 6 in. apart; and the space between their points of attachment to the bridge, about 9 ft. 3 in. The substance of these bars averages full 2 in. by 1 in.: they are welded in entire lengths, and connected on each side of the pyramid by two bars 3 in. by ½ in., bent in the direction of the strain, and fastened by gibes and keys. On each side of the pyramid is inserted a cast-iron plate from the base to the top suspending bar, cast with holes through which these connecting bars pass.

The beam is composed of two bars of wrought-iron 7 in. by ⅞ in. thick, in lengths of about 18 feet each, properly arranged so as to break the joints, and connected by brace plates. At the edge of each suspending bar which connects with the beam of the bridge, is welded an upright piece of iron about a foot long, of the same substance as the upright supports; and to this the upright supports are attached by coupling joints. In the uprights are proper eyes made, through which the suspending bars pass and are made tight by a wedge above and below the bar, and covered over with a cast-iron rosette. Each suspending bar is attached to a round iron bolt 2 in. diameter, which passes transversely to connect the two ribs or beams. At the land abutment, the rib or beam is secured to cast-iron chairs held down by strong iron bolts, which latter are secured to cast-iron plates inserted in the foundation. The railing on each side of the bridge, is filled in with iron bars placed upright; which are omitted in the drawing to prevent a confusion of lines.

The weight of wrought-iron in the suspending and upright bars, is about 7 tons; the whole weight of wrought iron, including transverse bolts, beams or ribs, foundation plate bolts, railing, &c., about 18 tons: of cast iron about 5 tons.

The floor of the bridge is composed of Memel joists and oak platform. The joists are 12 in. deep and 3½ in. thick: beveled off on the top from the centre to 10 in. The flooring boards are about 9 in. wide, and 2½ in. thick: they are covered with a thick coating of coal tar and sand, on which is laid screened gravel of an average thickness of 3 in., and in a convex form.

The following was the mode of construction adopted. The land ends of the bridge were first erected; the middle portion over the towing path and river was constructed by means of a platform or hanging scaffold suspended horizontally by means of ropes and pulleys from the top of the pyramid. This platform was chained to the iron-work as it was extended out; so that the bridge was carried over the river without any support from beneath.

The foregoing description will, it is presumed be sufficient to enable those who are acquainted practically with iron, to form an idea of the principle on which the bridge is built, and its effect. It may however be observed, that the principle is that of the inverted bracket, converting the force of compression into that of tension, and at the same time preserving as much compression as circumstances will permit. It must be evident even to the most superficial observer, that this mode of construction and arrangement must be less flexible than a chain; and practice has proved that for stability it is unquestionably next to cast iron. Loads of timber of from six to eight tons have passed over this bridge without producing any visible change in the floor; indeed none can be made without either breaking or elongating the bars, except so far as the natural elasticity of wrought iron will allow.

The power of the above bridge may be nearly ascertained by treating it as a lever, which is unquestionably the law by which it is governed. Thus the first suspending bar descends to the bridge at 2 ft. 6 in. from the base of the pyramid, and extends on the floor nearly 10 ft., which is four times the height: consequently one ton at the end would produce a strain of four tons at the pyramid: and so on in like proportion with each of the upper bars. Now there are 24 suspending bars, averaging a section of full 2 in. to each bar, which makes 48 in.: then supposing one inch of best cable iron to support 20 tons, 48 in. would support in a direct or perpendicular strain 960 tons. But the leverage being as four to one, they would only support

a uniform load of 240, the weight of materials included; or on the whole length of the bridge, a uniform load of about 480 tons. Thus if the proportion of material were increased say 50 per cent, it is presumed that this bridge would be amply sufficient for *railway purposes*, even with such ponderous engines as are used on the Great Western Railway.

The cost of the above bridge, including the expense of masonry and very deep foundations, exclusive of embankments and approaches, was under 2,500*l.* Provided only that it be duly painted, it is presumed that the iron-work will endure even for centuries without requiring repairs of any consequence; as may fairly be expected from its comparatively inflexible nature, and the almost entire absence of friction.

EXHIBITION AT THE ROYAL ACADEMY.

ARCHITECTURAL ROOM.

(*Continued from p. 225.*)

By following the order of the numbers in the catalogue, we are doing that which we ourselves complain of as a fault in the exhibition,—namely, jumbling subjects of all sorts *together*, instead of attempting to classify. No matter,—having so begun, so we must now proceed· and therefore start afresh with No. 1088. "Design for an ornamental arch to be erected in a nobleman's park," T. A. D. Monies; where we have the monument of Lysicrates, merely set upon what would otherwise be a very every-day affair. This kind of architectural addition—for combination it can hardly be called,—seldoms fails to produce heterogeneous, centaur-like buildings; nor does the present drawing form an exception. Something good might be made out of such an idea; but it would require some study to unite the two portions ably together, and to give the whole the appearance of having been fused—not con-fused—in the same mind. Besides it amounts to downright plagiarism when we see so considerable a portion transplanted entire.

The three next Nos. 1089–91, consist of elevation, bird's-eye view and section of a design for a National Museum, by W. L. B. Granville. As carefully executed drawings, these are entitled to much praise; and are withal quite of the orthodox Italian school, but at the same time in that fashion of it which is now considered *passé* even by those who wish to recall the style itself. The elevation is composed of two orders, both Corinthian, the lower one in attached columns, the upper in pilasters,—which by the-by, seems to be reversing the natural order of things. The upper floor has niches instead of windows, decorated very much after the manner of those similarly placed in the side elevations of St. Paul's. Each niche moreover is placed within a large arcade, on a ground of rusticated wall, which produces an effect more singular than happy in its novelty. The whole is crowned by a dome with a series of small circular windows just at its base, yet owing to its not being raised on a tholobate, little more than just the upper part of it could be seen from below; and therefore it was, we presume, that in order to show it in perspective the artist made choice of a bird's-eye view; acknowledging thereby in fact, that one chief feature in the geometrical elevation would be nearly lost, were the building to be shown just as it would appear from a moderate distance; and so far, it would be desirable for the dome on the top of the National Gallery to be similarly conditioned. In our eyes the leading fault of this design is that it is in a style hardly any one would think of adopting at present for such a purpose. Nevertheless we perceive by No. 1197, that some one else has selected for the same purpose what with less originality is open to the same objection; for it looks "for all the world like the very moral," as Mrs. Slip-slop says, of the front of Mereworth in Kent.

Being now on the subject of Museums, we may as well dispatch a third, viz., Nos. 1146, and 1166 by R. Penson. Unlike the other two, this is quite Greek, and has a lofty central mass advanced boldly before the wings, and forming an Ionic octastyle in front. In the wings which may be described as consisting of colonnades and extreme pavilions connected by them with the main building, the order is Ionic. Very probably this design was one of those for the Fitzwilliam Museum at Cambridge.

No. 1098, "an attempt at a Polychromic restoration of the Choragic Monument of Lysicrates," C. Vickers; does not attempt to convey any idea of the effect of such decoration; for not being in perspective nor having any background, it does not enable us to judge what would be the appearance of a building thus artificially and floridly coloured, when seen in combination with the objects around it;—though this is precisely the very point in regard to which we are most at a loss.

No. 1102, by C. W. C. Edmonds has much merit both in respect to drawing and design; but the appellation of "Ionic Temple" is rather an unfortunate one, and likely to excite dissatisfaction, the thing itself having far more the air of a casino or other garden building.

No. 1103, "Interior of the Great Hall, forming part of a Gentleman's Residence in Surrey, erecting under the superintendence of B. Ferrey," would be entitled to much praise were it no more than an ably executed architectural portrait. So far this interior loses nothing by its proximity to No. 1066, which we highly commended in our preceding notice,—though not at all more than it deserves; while it is handled with great freedom and mastery, it is free from negligences in regard to architectural forms and details; and has therefore the merit of being correct without any of that hardness, stiffness, and formality, which it is so difficult to avoid without surrendering up something of accuracy likewise. The design itself is a remarkably good application of the Tudor style; and the apartment upon such a scale as to show it off to full advantage, it being a remarkably lofty one with an open timber ceiling or roof.

We now arrive at what will perhaps generally be considered the *lion* of the season in the architectural room,—namely, Mr. Cockerell's "Tribute to the memory of Sir Christopher Wren," No. 1111: which both from its size, and from its being placed immediately opposite the door, catches the eye on first entering. For our own part we should have been better pleased had Mr. C. been a little less modest and claimed our admiration for himself, by vouchsafing to let us behold some ideas of his own—the designs, for instance, of the building he is now employed upon at Cambridge: or for the matter of that, he could have exhibited the last-mentioned subject likewise. Perhaps the reason for his not doing so is, because it would have led to the discovery that great as may be his veneration for Sir Christopher, it does not extend to the complaisance of taking him for a model; and indeed, when the first flush of admiration produced by this showy and alluringly arranged pageant has passed off, and we soberly examine the designs it is made up of, we must say—and it requires some degree of boldness to do so—we are not surprised that Wren's admirers should be exceedingly shy of becoming his imitators. We are of opinion that the same number of any other buildings—no matter what—similarly grouped together, to the exclusion of any thing else, and so as by combination alone to produce an uncommon and picturesque scene to the eye, would answer the purpose just as well; for many of those which help to compose this vision, are any thing but elegant or beautiful in themselves. The whole is like a royal procession, full of glare and bewilderment; yet as all those who figure in the one are not exactly Solomons or Adonises,—on the contrary there are many who upon a less imposing occasion would seem very poor animals,—so here too we perceive some buildings that in themselves are absolutely of the most dowdy quality. We have for instance in the very fore-ground, Temple Bar, flanked on either side by what, if we mistake not, were portions of old St. Paul's School; besides sundry other quaint and grotesque edifices which none save a bigotted admirer of their architect, would now presume to hold up for the general admiration of the rest of the world.

In the small drawing, No. 1116, "Design in the Elizabethan style," H. M. Bostock, there is more cleverness than in many which are far more likely to attract notice. But the next subject, according to the catalogue, "The Royal Institution, Manchester, built by Mr. Barry," is so tremendously vile that, were Charles Barry only half as sensitive and thin skinned as was John Soane of Bœotian memory, he would bring his action for libel against the unlucky wight who has here, through sheer ignorance, caricatured one of his earliest erected buildings, and one of the happiest and most original applications of Grecian architecture that we possess.

Its neighbour, No. 1118, is on the contrary a very good drawing of a very interesting subject, all the more interesting too for belonging to that class of which so very few specimens are exhibited. Not one person in a thousand who are acquainted with the exterior of Fishmongers' Hall, either from the building itself or from prints of it, knows anything whatever of its interior; and few can fail to be captivated by this view of the Banqueting Hall, which shows the whole of that noble apartment from the end adjoining the Court drawing-room, and looking towards the music-gallery, above which is seen the panel of stained glass representing the Company's arms, corresponding with another at the opposite end containing the Royal arms. These transparent panels,—for such is their character rather than that of windows,—are elegant novelties in the design; and the gallery just alluded to is very happily managed so as not at all to interrupt the order,—as is the case in the similar apartment at Goldsmiths' Hall,—but rather so as to give greater energy to it in that situation. One thing that strikes very much in the drawing, but which we do not remember to have at all observed in the room itself, and therefore question whether it has been executed,—is the socle of bright green marble, which contrasting in colour with all the rest, gives such a finish to the bottom of the walls.

Whether it be owing to amiable diffidence or to mauvaise honte, we pretend not to say, but certain it is that architects seldom care to exhibit drawings of the buildings they have erected. Such is not the case, however, with Mr. Vulliamy, who after having sent last year a large elevation of the new front of the Royal Institution, has now sent a perspective view of it (1119) upon the same scale. This drawing cannot be charged with attempting to impose upon the eye by the "painted rhetoric" of showy colours, and artist-like but deceptive effects; for it is only slightly tinted in sepia, and makes no pretension to effect even of light and shade. The design itself is equally flat and insipid, consisting of nothing more than a range of Corinthian columns put up against what neither was originally intended for them, nor has been since adapted to them. The best that can be said of it, is that the front as now altered serves to distinguish the Royal Institution from the other houses in the street.

No. 1128 "Malpas House, Monmouthshire," T. H. Wyatt, has much merit in the design (in the Tudor style) and as a landscape drawing. No. 1130 "Architectural composition exhibiting elevations of the Derby Athenæum and other buildings in progress," R. Wallace, manifests much taste and ability. The style may be said to be a liberal and intelligent version of Greek; adapting it to elevations where windows are indispensable, and columns if introduced used at all, can be only ornamental accessories. The ground floor of the Athenæum has in the centre three triple windows, above which are five windows, with a continued panel of bas-relief over them; and this part of the elevation is terminated by an attic decorated with pilasters without windows, which latter are introduced only in the attic over the extremities. The great

breadth of the piers between the ground floor windows, and the additional openings over them on the upper floor, produce an effect very good in itself as well as unusual; wherein a certain degree of irregularity—namely, the want of exact conformity as to the number of windows on a floor—tends to impart the air of a more studied arrangement to the whole. The two other elevations shown in the same drawing are those of the Royal Hotel, and the Derbyshire and Derby Bank, to the former of which we give the preference.

No. 1138, "Landoge Priory, Monmouthshire, erecting for J. Gough, Esq.," by Wyatt and Brandon, is but of *so-so-ish* design;—a goodly-sized house in that spruce cottage fashion which has been wickedly described as being like "a pigstye just taken out of a bandbox." There is an air both of formality and poverty about it, the reverse of agreeable, inasmuch as each of those qualities is rendered more offensive by its alliance with the other.

(*To be continued.*)

PATENT FIRE-PROOF COMPOSITION.

ATTEMPT TO FIRE AN EXPERIMENTAL FIRE-PROOF HOUSE.

A patent has lately been taken out, for a new fire-proof plaster, for the protection of buildings of various kinds, and of different materials, from fire: and a company is in process of formation with a view to the effectual working of the patent and the general introduction of the new material. Several experiments have been made to test its efficiency; one at White Conduit House in November last; and two others at Messrs. Christy and Co.'s glass works, Stangate, in the month of May. A more public exhibition, to which attention was called by posting-bills, was made on Wednesday the 6th ult., at a dwelling house in Dorset Street, Clapham Road; the proprietors expressing their intention of thus giving a final proof of the indestructibility of their composition by fire. A considerable crowd was collected: and the profession were accommodated by tickets of admission to the enclosure surrounding the house, and to the house itself, both before and after the firing.

The house in question is one of a pair of small six-roomed houses, standing detached and unfurnished: the patentees appear to have found it in carcase, or roofed in and with the joists for the different floors in their places; and to have carried it forward themselves to the state in which it appeared on the day of the experiment. On the ground floor, it contains two rooms, the ceilings of which were formed as usual, only using the fire-proof plaster. With a view also to supporting the weight of the plaster, strips of iron hoop were nailed across diagonally to the joists after the first rough coat had been applied. A floated coat of plaster being added afterwards, and whitewashed, there was no appearance in the ceilings to attract notice. The front door posts were likewise coated with the composition; they were painted, and appeared to take the paint perfectly well; one patch was left uncovered to show the material, which is of a greyish slaty colour, and receives a very smooth surface from the trowel. The face of the bond timbers built into the walls was coated with the plaster, and the walls themselves left bare. In these rooms no floor had been laid down, but the earth was left uncovered.

A substantial timber step ladder led to the first floor; it was coated with the composition, the thickness of which when applied to timber is usually about an eighth or three-sixteenths of an inch. Here the ceilings and walls of the two rooms were prepared as already described. The floors likewise were covered with the composition, and as we were given to understand, the joists likewise. Another step ladder led to the second floor, the rooms of which were prepared in the same way. The house was not fitted with either doors or windows, or any wood work beyond what has been mentioned; nor had it any of those quarter partitions which are so well known to help to spread a fire from one floor to another.

Shavings and wood were distributed in all the rooms; sufficient probably in each to set on fire the floor of an ordinarily constructed apartment. But the front room on the first floor had some additional preparations, which must be mentioned. Above the composition protecting the boards of the floor was spread a veneer of half-inch deal boards; in order to show that the usual appearance of a boarded floor might be had if required, in the fire-proof room. A bedstead with bedding and curtains, a set of chairs, a chest of drawers well filled with shavings and left negligently open, completed the furnishing of the room;—not splendid certainly, but adequate for the purpose, and good enough to burn.

The experiment commenced by firing the fuel on the floor of the top front room: the flames made no great show, and people said there was not enough heat to try the material; still we fancied in an ordinary house such a bonfire on the floor of an upper room would have spread certainly downwards, probably upwards;—here it died out harmlessly. A similar result followed the firing in the top back room. Then came the experiment to which we looked with most interest, the firing of the furnished lodging room. Here the flames burst out furiously, and would by night have looked terrific; as it was, the volumes of smoke, especially that which issued through the chimney, showed that everything was alight and the heat rising powerfully. It soon took effect on the ceiling, so far as to detach the smooth floated coat of plaster in large patches; and the crowd hooted and fancied they were going to have a real instead of a sham fire. We had understood however that this might and probably would happen; and we looked on with interest to see what next would come. The ceiling continued firm, the floor exhibited no signs of giving way, and the fire here too died out, not spreading beyond the room. The wind, we should observe, set from back to front, but not very strongly. On going into the room underneath, while the fire was still too hot to allow us to go into the lodging room itself, we found the ceiling as perfect as ever, apparently totally unaffected by what was going on above. Subsequently the fuel was ignited in the back rooms, first the upper one, afterwards the lower; but these experiments did not exhibit any new feature, except that the step ladders were exposed to the fire, which however was not very powerful though sufficiently so we think to have kindled them had they been unprotected. We left when the experiment seemed to be concluded, satisfied that the front room first floor especially had stood a severe test, and determined to examine it minutely when cool next day.

The next day accordingly we carefully examined the house. To mention first the rooms which had been the least severely tried; the floors were all firm and safe though blackened, and the plaster changed in colour to a dingy brown, something like Roman cement. We do not know how many fires it is expected to stand; but we suppose only one, as it *will* crack off in parts by heat. The ceilings were also sound, with the exception of some slight cracks; and a small patch or two of the floated coat had come off in the upper rooms which were rather low, and thus their ceilings more exposed. The bond timber in the walls was well saved; the step ladders uninjured, but we detected a few parts peeled off especially where there was iron underneath. The iron expanding by the heat seems always inclined to throw off the plaster: the patentee intends to dispense with it in his ceilings for the future, where he does not consider it necessary; we do not know however with what material he designs to supply its place, and we greatly doubt whether something is not required to prevent the ceiling peeling off the laths by the force of the fire.

We were sorry not to find the front room on the first floor just as it remained after the fire of the previous day. We were informed that several scientific and professional gentlemen had been desirous of further testing the composition, with the view to ascertain what heat it would bear without transmitting sufficient to ignite the timber. For this purpose they had kept up a continued fire on one part of the floor and against the bond timbers of the wall, and had succeeded in extensively charring the wood underneath. The floor had also been removed in a great measure, in order to take up some gunpowder which had been deposited in papers underneath it. And here we must protest against this part of the experiment: it shows indeed the confidence of the patentees, and it has proved to have been a successful piece of rashness. Still rashness it was, we maintain; and gratuitous rashness. If the proprietors could prove that their prepared room would stand the burning, what need for anything further? They might have waited for *this* experiment, till they were rendering fire proof the first gunpowder magazine to which they may be called in.

We were informed that on clearing away the rubbish previous to taking up some of the boards of the floor, the boards were found very little injured. We can speak ourselves to the perfect soundness of the joists beneath: and we were personally beholden to the strength of the ceiling attached to them, as we chanced to stumble and come down somewhat heavily upon it, without damage. We have said that in removing the plaster from some of the bond timbers which had borne a long-continued firing, we found them charred. It is but fair however to state, that they had been built into the walls, without being coated all over; so that the fire was able to creep round them as the lime mortar crumbled away, which might not have been the case had they been prepared all over. The same remark applies to the upper lintel of one of the windows, which caught fire.

The company in their prospectus state, that their composition is applicable to "walls, ceilings, partitions, staircases, &c." In this experiment we have shown its application to the first two purposes: the possibility of applying it effectually to staircases, we doubt much; we do not think the material would stand the wear of feet passing up and down; and the plan of veneering over with thin boards does not seem practically applicable. So also in case of floors; the thin boards though at first lying flat enough, would after a few washings become hollow, and the floor uneven and unsightly. The composition itself looks uncomfortable to an eye accustomed to a boarded floor; and it remains to be seen how it will wear under carpets. The old plaster floors, still used in some parts of the country, will stand the heat of a fire upon them for a long time: not so however the joists by which they are supported, which must give way to fire underneath and let fall the heavy plaster floor. We have mentioned the colour of the composition; in other respects it appears much like common plaster: but as the patentee has not yet enrolled his specification, we cannot speak with any degree of certainty. It will be seen also, that the security afforded by it depends upon the coating not peeling off.

BLOWING UP OF WRECKS IN THE THAMES.

Colonel Pasley has lately been engaged in two important applications to practical purposes in the arts of peace, of his military attainments as Colonel in the Royal Engineers. His experiments on mining under water have been hitherto conducted on a small scale "upon casks loaded with gravel, or small unserviceable punts, &c.," merely for practice and the acquisition of knowledge. But his complete success in these two larger undertakings, will we fancy leave the corps of Royal Engineers no need to complain of want of practice in sub-marine mining: and navigation will be benefitted at the same time, by the removal of wrecks from the beds of navigable rivers.

We proceed to describe the first explosion; its process and its effects. It was required to remove the wreck of the collier brig William, of 400 tons burden, laden with a cargo of 300 tons of coal, sunk off Gravesend near Tilbury Fort, in about 23 feet water at the lowest tides. For this purpose, two cylinders each capable of receiving a charge of 2,500 lbs. of gunpowder, were

prepared at Chatham Dock-yard. They were made of lead, and surrounded with a casing of elm, 3 inches thick, 10 feet long, and 4 feet diameter; which was further strengthened by longitudinal bars connected at the ends by a framing. It was also hooped with iron; the hoops being however nearly cut through on the side intended to be next the brig, that the force of the explosion might be employed in the most profitable manner. Into the cylinder was fixed a fuze, communicating directly with only a small powder canister in the centre of the charge, to guard against extensive damage by the accidental admission of the water. The mode of explosion adopted, was by a small powder hose guarded by a leaden pipe. The fixing of the apparatus caused considerable trouble and delay. In the side of the wreck were fixed ring bolts to which the cylinder was afterwards attached: these operations were performed by means of the diving bell and diving helmet. The operations were conducted by a body of Royal Sappers and Miners, under the command of their officer, Captain Yule; the whole under the direction of Colonel Pasley, assisted by other officers connected with the naval establishment at Chatham. Operations commenced on Monday, May 21, when by some unfortunate accident, the life of a diver sent below to fasten the bolts, [illegible] the next day, the fuze and small canister attached were spoilt by [illegible] irruption of water, when all seemed ready for the explosion. Then at night the lighter employed above the wreck was run foul of by a ship passing by, and the working gear carried away. It was not till Monday, May 28, that the expected explosion took place. When all was ready, and signals made to keep all craft clear of danger, the fuze was fired by a party of miners in a cutter. It burnt for five minutes, giving time for the party to make their escape safely. The explosion appears to have been terrific; by land it was felt distinctly, though without damage, in all the neighbouring houses; and the water of the river was thrown up in a column, some say 70, others 100 feet high. The dense black vapour which arose at the same time, showed that the cargo of coals had been effectually reached; and the floating masts, planks, and timbers, proved that the wreck was entirely demolished.

It will be seen that the above account bears us out in our assertion in a former article (No. VIII., p. 198), that the ordinary mode of firing is uncertain except at moderate depths;—indeed here the depth was very moderate. The difficulty is of course increased by the strong tide of the Thames, and by the passing of craft in the river. We should however like to see Mr. Bethell's galvanic apparatus, which we described in the article referred to, fairly tried on some early occasion of a similar kind.

The other explosion which we design to mention, took place under the same able direction on Tuesday, the 5th ult. The wreck was that of the schooner Glamorgan, sunk athwart the channel of the Thames a little to the Westward of Coalhouse point, Gravesend Reach. The depth of water was five fathoms before the explosion, and from seven to seven and a half afterwards. The visible effect Colonel Pasley describes as "a very brilliant cone of clear water, sparkling in the sun, probably thirty or forty feet high, succeeded by a second water spout of a dark appearance, being mixed with mud from the bottom, and tinged by the gunpowder." Timbers, planks, &c., were found abundantly floating, as in the former instance. The charge of powder by which this effect was produced, was the same in amount, and in application, as that before described. Indeed it had been at the bottom twice before; once in one of the abortive attempts before mentioned; again it miscarried in consequence of the fuze pipe proving unsound owing to the damage received in a previous service; the third time, and with a new pipe, we have seen that it completely succeeded.

In a letter of Colonel Pasley's, dated the 5th ult., from which we have taken the above particulars of that day's operations, there are some interesting observations on sub-marine mining which will be interesting to the professional reader, and are important as resting on the gallant author's experience. In shoal water, and in a situation not exposed to such strong tides, he would prefer a number of smaller charges, not exceeding 40 lbs. each. Such charges have been previously applied in a ship's bottom as near the keel as possible. But it is often desirable to remove only the decks without injuring the rest of the vessel more than is unavoidable, to enable the divers to reach the cargo; or in the case of a steamer, to get out the engines. For this purpose says the Colonel, "I was induced on Saturday last, to fire an experimental charge of about 40 lbs. of gunpowder against the deck of the same schooner which we destroyed to-day; and, as it may not always be convenient to place charges of gunpowder under the decks, I placed this charge above and upon the deck of the forecastle of the schooner. On firing it, some pieces of plank came up to the surface; and on examining that part of the deck after the explosion, it was found that a hole had been made in it; and that the planks near it, which before were quite sound, had been loosened in consequence, and the iron bars with which the vessel was laden might be felt, though before they had been inaccessible."

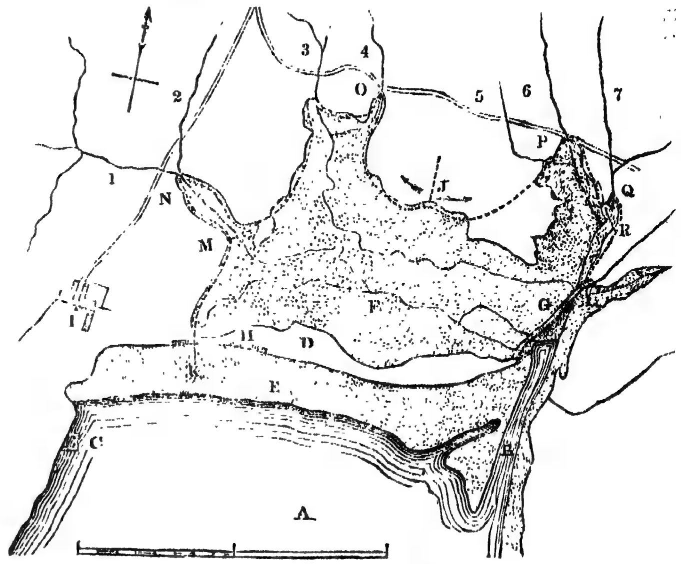
On the success of these operations, we congratulate both the able con[illegible] of them, and those who will be benefitted by them,—all concerned in [illegible] of the river. Further experience will we doubt not abridge the [illegible] and increase the certainty of the process, till it becomes the ordinary [illegible] to blow up such wrecks as it is found impossible to weigh.

The French papers of March, notice with praise an equestrian statue of Emanuel Philibert, Duke of Savoy, by M. Marochetti, cast in bronze by M. Soyer, which has been recently set up in the interior court of the Louvre, previous to its being forwarded to its destination, in Chambery, the commission having been given by the King of Sadinia. It is said, too, that thirty-five statues of marble, for the niches beneath the colonnade of La Madeleine, have been recently ordered by government, and 6000 kilogrammes of bronze, delivered, by royal command, to the town of Albi, for a statue of La Peyrouse.

TRAMORE STRAND, IRELAND.

(Continued from p. 229.)

[We repeat the map given in our last number, p. 227, with the addition of certain letters and figures of reference for the explanation of the following additional extracts from the Report.]



Furlongs 8 0 1 Mile.

References to the Map.

A, Tramore Bay as it appears at low water.—B, Rhineshark Channel.—C, Proposed Pier.—D, the Burrow, or neck of land, dividing the Front and Back Strand.—E, Front Strand of Tramore, which is covered at high-water. F, the Back Strand, now covered at low-water, which it is proposed to embank in, and thus reclaim.—G, Embankment to be made.—H, Sea-wall to be erected to strengthen and protect the narrow and weaker portion of the neck of land between the two strands.—I, the town of Tramore.

The dotted lines show the new catch-water drains which it is proposed to construct to carry off the water flowing from the rivers. The summit level of these drains is at J, from which point they fall to the East and West, as shown by the arrows. The Eastern drain discharges itself at L, in the Embankment G, just below high-water mark: and the Western one flows out at K, in the sea-wall H.

Further Extracts from Mr. Bald's Report.

Having reported on the Back Strand of Tramore, and made out an estimate of the expense of embanking it in from the sea, I shall now proceed to describe the mode of discharging, by catch-water courses or drains, all the brooks and rivers which flow into it; and how it is to be sub divided by drains and fences, together with the general extent of the enclosures.

The extent of country draining into the back strand proposed to be embanked in, amounts to 9,100 acres, and which feeds eight brooks and streams; the quantity of water found in them by measurement on the 29th of January, 1838, amounted to 2,004 cubic feet per minute. At present, all these brooks and streams run through the back strand, and pass out by the straits of Rhineshark: by inspecting the map, it will be seen that it is proposed to give the river waters two points of discharge,—one at the point K on the front strand, into the sea,—and another at the point L into the Rhineshark channel at the Eastern end of the great embankment G. These points of discharge are to be above the level of high water spring tides.

On the Western side of the strand, a catch-water drain is to be constructed, commencing at the point O; and which is to be carried along by the foot of the high land, through M, to the discharging point K at the front strand. This catch-water drain in its course will receive the waters of the brooks and rivers marked on the map Nos. 1, 2, 3, and 4. The upper part of the catch-water drain from O to M, will be 3,300 yards long, 10 feet wide, with a sectional area of 1,728 superficial inches, a mean hydraulic depth of 13.29 inches, and a fall of 18 inches in a mile: it will convey more than 1193.40 cubic feet per minute. A section of it is shown in fig. 1. The catch-water drain from N which is to convey the waters of the rivers Nos. 1 and 2 to the point M, is to be 880 yards long, 15 feet wide, with a sectional area of 3,600 superficial inches, a mean hydraulic depth of 18.55 inches, and a fall of 18 inches in a mile; it will discharge more than 2,880 cubic feet per minute. A section of it is shown in fig. 2. At the point M the waters of the brooks and rivers Nos. 1, 2, 3, and 4 will be united; and from this point M, to the discharging point K on the front beach, there is to be a catch-water drain of 18 feet in width, 1,320 yards long, with a sectional area of 5,184 superficial inches, mean hydraulic depth 22.34 inches, and a fall of 18 inches in a mile; it will discharge more than 4,642 cubic feet per minute, the mean daily average quantity per annum being under 1,140 feet per minute. A section is shown in fig. 3.

The water received by the catch-water drain extending from O to P, 6 feet in width, and 4,480 yards in length, will be in equal portions delivered into the catch-water discharging drains on the western and eastern sides of the back strand, from the point marked J on the map.

On the Eastern side of the back strand, a catch-water drain is to be constructed from the rivulet No. 6, P to R, 1,320 yards in length and 10 feet wide; and from No. 7, Q by R to L, a catch-water drain of 15 feet in width. This latter drain, with a sectional area of 3,600 superficial inches, a mean hydraulic depth of 18.55 inches, and a fall of 18 inches in a mile, will give a discharge of 2,880 cubic feet per minute (see fig. 2); the mean annual discharge is under 864 cubic feet per minute. All the catch-water drains round Tramore back strand, are to discharge their waters into the sea above high water spring tides, at the points marked K and L; or they may be made to pass wholly out by the Rhinesbark channel.

Having shown how all the land waters running to Tramore back strand can be discharged into the sea without passing through the strand, it now becomes necessary to calculate the probable quantity of rain water which falls within the back strand. The area of the land proposed to be embanked in, is 1,425 English acres: taking the annual quantity at 36 inches in depth for rain and springs, &c. over this surface, the following will be the result:—

$43{,}560 \times 3 \times 1425 = 18{,}621{,}900$ cubic feet per annum.

$\frac{18{,}621{,}900}{365} = 51{,}018$ cubic feet per day.

$\frac{51{,}018}{28} = 2{,}126$ cubic feet per hour.

$\frac{2{,}125}{60} = 35 \cdot 4$ cubic feet per minute.

It is proposed that this quantity of water shall be sluiced out through the great embankment G; and also through the beach into the sea at the point K: or it may be more effectually discharged by a small steam engine of fifteen horse power.

It is proposed to run a main line of road from near the town of Tramore through nearly the centre of the whole back strand; another line of road from the embankment to the point marked P on the map; and a third from the Western end of the Burrow, crossing the whole strand in its greatest breadth: these roads are to be twenty five feet wide, and to be constructed in a solid and substantial manner. From these main roads there are to branch four narrower lines of road crossing the back strand in various directions; they are to be eighteen feet wide.

The back strand has been divided into compartments containing about fourteen and a half acres each; these are to be separated from each other by drains from six to eight feet wide, with an earthen fence on each drain side formed with the material excavated out of the drain, and which may be planted with osiers.

It would be necessary to shut out the Burrow D, and fix a portion of the moving sand of which it composed, that it might not spread and blow in upon the part of the back strand adjacent to it. A broad screen or belt of planting throughout its whole length, might effectually prevent the sand blowing in. The moving sands at Bordeaux in France, have been arrested and fixed by being planted over with trees; and I think that the moving sand on the Northern edge of the Burrow bounding the back strand might be secured in a similar manner. For, although the position is very maritime, yet from the height of the sand hills, the Burrow would afford to the growth of trees on its side great protection from the prevailing Westerly gales.

In the report already furnished, it was recommended in the first instance to lay down a stone rubble dyke, in the line of the proposed embankment G, in order to intercept the alluvial matter carried into the back strand by the brooks and rivers; this operation would raise the surface of the strand by depositions of the most valuable kind. And if it should afterwards be nece[illegible] to sweeten the soil of the back strand, and free it from any super abun[illegible] saline matter that it might contain, its whole surface could be inundated with fresh water, and sluiced off seawards, as frequently as might be required. The sectional areas of the sluices will be equivalent to 119 superficial feet.

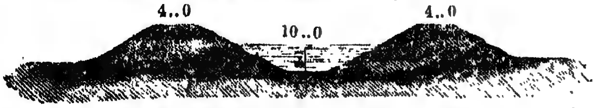
From the rich nature of the soil of the back strand, and from an experiment having been made by enclosing a very small part of it, which gave an abundant return, I am of opinion that the greater part of it will be found to produce luxuriantly both green and grain crops of all kinds, as soon as the sea has been shut out by embankment.

(*Signed*) WILLIAM BALD,
Civil Engineer.

Dublin, 1838.

DRAWINGS AND CALCULATIONS ILLUSTRATIVE OF THE REPORT.

FIG. 1.—Section of Drain from O to M, and from P to R.



This drain, with a fall of 18 inches in a mile, will give the following discharge.

Let μ = mean hydraulic depth.
λ = twice the descent in inches per English mile.
v = velocity.

$v = \cdot 91 \sqrt{\mu\lambda}$

$\sqrt{24^2 + 48^2} = 53$ Inches.

$2 \times 53 + 24 = 130$ Periphery in inches.

$\frac{120 + 24}{2} \times 24 = 1728$ Sup. inches sectional area.

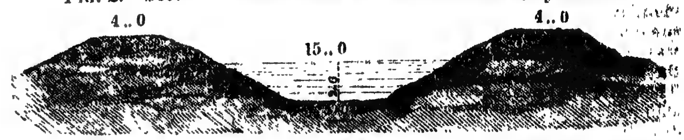
$\frac{1728}{130} = 13 \cdot 29$ Mean hydraulic depth.

$\cdot 91 \sqrt{13 \cdot 29 \times 36} = 19 \cdot 89$ Inches velocity per second.

$\frac{19 \cdot 89 \times 1728}{1728} = 19 \cdot 89$ Cubic feet per second.

$19 \cdot 89 \times 60 = 1193 \cdot 40$ Cubic feet per minute.

FIG. 2.—Section of Drain from N to M, and from Q by R to L.



This drain, with a fall of 18 inches in a mile, will give the following discharge.

$v = \cdot 91 \sqrt{\mu\lambda}$

$\sqrt{60^2 + 30^2} = 67$ Inches.

$2 \times 67 + 60 = 194$ Periphery in inches.

$\frac{180 + 60}{2} \times 30 = 3600$ Sup. inches sectional area.

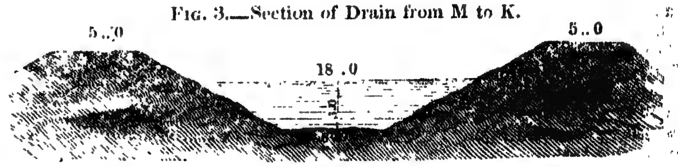
$\frac{3600}{194} = 18 \cdot 55$ Inches mean hydraulic depth.

$\cdot 91 \sqrt{18 \cdot 55 \times 36} = 23 \cdot 49$ Inches velocity per second.

$\frac{3600 \times 23 \cdot 49}{1728} = 48$ Cubic feet per second.

$60 \times 48 = 2880$ Cubic feet per minute.

FIG. 3.—Section of Drain from M to K.



This drain, with a fall of 18 inches in a mile, will give the following discharge.

$v = \cdot 91 \sqrt{\mu\lambda}$

$\sqrt{72^2 + 36^2} = 80$ Inches.

$2 \times 80 + 72 = 232$ Periphery in inches.

$\frac{216 + 72}{2} \times 36 = 5181$ Sup. inches sectional area.

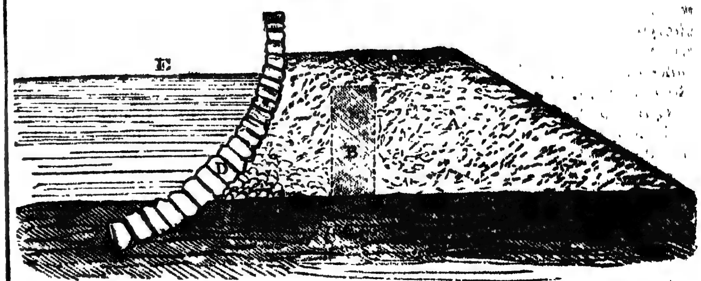
$\frac{5181}{232} = 22 \cdot 34$ Inches mean hydraulic depth.

$\cdot 91 \sqrt{22 \cdot 31 \times 36} = 25 \cdot 79$ Inches velocity per second.

$\frac{5181 \times 25 \cdot 79}{1728} = 77 \cdot 37$ Cubic feet per second.

$77.37 \times 60 = 4642$ Cubic feet per minute.

FIG. 4.—Section of Embankment G.



References.

A. Embankment, 15 feet high and 18 feet wide on the top, with a slope of $1\frac{1}{2}$ horizontal to 1 perpendicular.
B. Puddle Dyke, 12 feet high by 4 ft. 6 in. broad.
C. Natural bed of the bay.
D. Stone wall, the top 4 feet above the embankment.
E. High water mark, spring tides; three feet below the top of embankment.

GREAT WESTERN RAILWAY.

The first portion of this important railway, from Paddington to Maidenhead, a distance of 23 miles, was opened on Thursday May 31st by an experimental trip being made by the directors and a party of friends; and on Whit-Monday June 4th, it was opened to the public. We deferred paying our visit until the 15th ult., that we might be the better able to judge of the works after a few days' trial; and we shall now proceed to make some remarks founded upon our observation on the day of the trip, and during the progress of the works.

We must first say a few words with regard to the opening of the railway thus early. We consider it a very impolitic measure, and the directors censurable for so doing; a considerably longer time ought to have been taken, and every engine tried before they opened the line to the public, instead of allowing daily failures in consequence of the defective state of the engines. Scarcely any of them, with only one or two exceptions, are of sufficient power to work on the line.

In consequence of the greater space between the rails, the carriages are of considerably greater weight than on other lines; the day we visited the line we were conveyed in a train consisting of one open carriage containing 72 passengers, and four close carriages containing if they were all full 24 persons each; making a total load of 168 passengers. With this load, the engine could not move the train at starting; the attendants were obliged to put their shoulders to the wheel and push on the carriages to give the train an impetus. We then went slowly on until we had gone a distance of about three miles, and here the engine was brought to a dead stand still, for about a quarter of an hour; we believe the fault was owing to some part of the carriage of the locomotive being defective; as after the engineer had done something to it, it progressed and performed the remainder of the journey at the rate of 20 to 25 miles per hour. We were informed that these delays have been frequent, and it is very evident that some of the engines cannot do their duty. When we were at Maidenhead, we noticed that some of the engines arrived five minutes within the hour, allowing for five minutes' stoppages at the two stations on the line; they must have travelled at not less than 27 miles per hour. This clearly shows that with proper attention to the power of the engines, the journey might be performed at the rate of at least 30 miles per hour; but even this is not a greater speed than what we understand is now being performed on the Liverpool and Manchester Railway.

We shall now proceed to make a few remarks with regard to the construction of the line. We shall first consider the effect of adopting 4 feet gradients, which have been obtained at an enormous outlay. In consequence of the great height of the embankments, and the lightness of the cuttings, a considerable portion of those embankments has been formed from side cuttings, and the soil drawn up inclined plains by the aid of stationary steam engine. If the gradients had been the same as on the Birmingham Railway, viz. 16 feet per mile, several feet in height would have been saved in the embankments, and the cuttings would have been deeper; by which means sufficient soil might have been obtained, without having recourse to side cuttings, and thus several thousand pounds might have been saved both in the embankments, viaducts, and bridges. We very much doubt if there be any great saving by adopting 4 feet gradients; for if the gradients do not exceed the angle of repose, say 16 feet per mile, there is as much saved in the descents as nearly if not quite compensates for the ascents. This point will be set at rest very shortly by a comparison of the working of the two great railways, the Birmingham and the Great Western. So in like manner will be seen the advantages or disadvantages of the two different gauges for the rails, viz. 4 ft. 8½ in. and 7 feet; up to the present time it is impossible to say which is the best.

Much discussion has taken place relative to the system adopted by Mr. Brunel for laying the rails, explained in a former number of the Journal, (No. VII. page 166*). It would be premature to offer an opinion on the merits of the system; we must wait for a short time, and see what effect the engines will have produced on Mr. Brunel's rails after two or three months' working. It is very evident from the immense number of hands employed to keep the ground-work packed under the sleepers, that they require as much attention as on other lines where time has not been allowed for the embankments to settle and become consolidated.

We very carefully examined the bridge over the river Thames at Maidenhead. It consists of two flat elliptical arches, each 128 feet span and 24 ft. 3 in. rise or versed sine, constructed of brick and cement; the thickness at the springing is 7 ft. 1½ in., and at the crown 5 ft. 3 in. The arches are turned in half brick rims and bonded occasionally with whole bricks through two rims. We regret to say that there are evident symptoms of failure in the Eastern arch, the centering of which has been eased or lowered 3 or 4 in. A space remains of about 4 in. between the lower part of the arch, the haunch, and the centering; and there is also a space between the under side of the crown and the centering: but that portion of the arch between the haunch and the crown has followed the centre and rests upon it: whereby it has forced up the crown and crippled it, causing also two vertical fractures in the Eastern spandrels. The other arch seems to stand firmly, although there is a slight appearance of the vertex or crown of the arch being crippled, but not dangerously so. The abutments appear to be very secure; the materials are of the best description, the bricks are hard, well burnt stocks, equal to marl paviors; there is no appearance of either the bricks or cement crushing. At the crown of the arch which is so much crippled, the cement curvilinear joints have divided, but not crushed. The centering is very strong, and the only objection we have to it, is allowing it to rest on piles driven midway in the stream. We decidedly prefer supporting the centering from the abutments, in a similar manner to the Waterloo Bridge centre, in which case more dependence may be placed on an equal settlement of the whole; and the centering is better eased by adopting the same description of wedges as used for the Waterloo Bridge centre. This is however quite a matter of opinion, and we have against us several eminent engineers who have adopted the same mode of construction as that of the Maidenhead bridge; we consider it a point well deserving of attentive consideration, as on the firmness of the centre depends the stability of the arch.

* By an accident in the press, two of the cuts, fig. 3 and 4, were inadvertently printed upside down.

Having said thus much respecting the Maidenhead bridge, we will turn our attention to the Viaduct over the Brent at Hanwell, consisting of eight arches, 70 ft. span each, and 70 ft. high from the level of the surface of the river to the top of the parapet. It is constructed of brick with Bramley Fall stone dressings, forming the bases, caps, cornices, and coping. The diminishing of the massive piers, the contour of the mouldings and the boldness of the whole, give an Egyptian architectural effect, which is particularly grand and imposing. We consider this viaduct decidedly the best piece of railway engineering architecture that we have yet seen on any railway. We wish we could say the same of the girder bridge over the Uxbridge road close by the viaduct. It appears as if it were placed there as a contrast, to show how vilely and how nobly works of railways may be designed. Mr. Brunel will, we hope, pardon us for this freedom.

The buildings at the Terminus and the Stations all appear of a temporary character, although constructed at a great expense; they are principally of timber, which we consider decidedly objectionable, particularly for the sheds under which the carriages and the locomotives stand, and where the latter discharge their burning fuel at the termination of their day's work. The danger arising from sparks, burning soot, and hot cinders, flying about and lodging on the timber of the roof, is fearfully great. The roof ought unquestionably to be of iron, as at the Birmingham station, notwithstanding that they may have been only erected for temporary purposes; as an iron roof might be as easily removed as a timber roof, if not more so; and the difference in the cost ought not to be a consideration for such a purpose, although a roof of iron is about double that of timber. At the terminus at Paddington is a polygonal building for the locomotives or carriages; this is a very economical method of construction for such purposes, as one turn plate in the centre answers for placing all the carriages in the several departments round it. In the case of a building of a longitudinal form, a turn-plate is necessary opposite every department, as in the engine and carriage houses at the Euston Square Station of the Birmingham railway; which is the cause of a very heavy expenditure for the turn plates only.

(*Continued from page 229.*)

Colonel Pasley on firing blasts under water by Bickford's fuzes.

Great advantage in blasting under water is derived from the use of Bickford's fuzes, applied to tin powder cases; also from the new system of tamping by means of small stones, and of fixing ring-bolts in stones or rocks, introduced by Mr. Howe. But the Bickford's fuzes are not altogether efficient in very deep water, say from 5 to 10 fathoms; though superior to any other in shoal water. The general practice has hitherto been, to ignite the powder contained in a tin canister, by dropping a piece of red hot iron down a tin tube reaching to the surface. The tin tubes being liable to failures, Colonel Pasley had used flexible leaden pipes, employing a piece of portfire instead of red hot iron, for vertical explosions. Several other means of firing, as small rockets, a quick match, and small linen hoses were tried; but without success. A small fine powder hose about one-eighth of an inch in diameter, secured so as to burn gradually instead of rushing forward and exploding, was found to succeed very well; but it is neither so simple nor so cheap as the Bickford's fuzes. These fuzes consist of so minute a thread of fine powder that they burn rather than explode, and are in no danger of bursting the case, which is made of twisted hemp coated with pitch, and so performs the double duty both of the hose and the metallic tube. The fuze having been ignited, is thrown on to the water, and generates a small column of elastic gas as it burns.

Colonel Pasley details several instances of the successful application of these fuzes, and proceeds to describe the general arrangements which were adopted by him; the fitting up of the tin cases; the mode of firing; the best borers for blasting under water; and a form of plug bolt peculiarly adapted for mooring and warping up rapids. The fuze was inserted through the cork, and upon the tin case was placed an iron cone having a small groove at the side of the base to admit the fuze; and the top of the hole was filled up with small pieces of hard stone of about three quarters of an inch in diameter, as tamping. The plug bolt, which is 3 feet long and 1¾ inch in diameter, (having about four inches of the bottom end spread out into a cone, of base about three inches,) is inserted in a hole cut a little oblique towards the current, and fixed in the same manner by pieces of stone. From experiments on tamping the holes of blasts with loose sand, it appeared that double the charge of powder was required to produce the same effect when the whole was filled with loose sand, as when filled by ramming in fragments

of bricks; but the method above described is far the most efficacious, saves trouble, and is less liable to accidents.

The Bickford's fuzes as originally made, were found several times to fail in 10 fathom water, and some larger ones burst the envelope; so that Colonel Pasley is of opinion that in deep water some other means should be resorted to. Also when a large quantity of powder is to be fired, the time which the fire is burning, namely about half an hour in 8 fathom water, keeps the experimenters in a great state of uncertainty as to when the fuze has ceased to burn: the small air bubbles sent up to the surface being generally imperceptible except at a small distance. In these cases the use of the small hose and leaden pipe is preferable.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At an Ordinary General Meeting of the Members, held on Monday the 11th of June, 1838,

P. Hardwick Esq. v.p., in the Chair,

The Right Honourable the Earl of Aberdeen, was elected an Honorary Fellow.

A letter was read from J. G. Wilkinson Esq. acknowledging his election as Honorary Member: also the following letter;

To the Right Honourable the Earl de Grey,
President of the Institute of British Architects, London.

My Lord,

The medal and the copy of the transactions of the Institute of British Architects, which your Lordship did me the honour of sending, were delivered to me a few months ago by Lieut.-Col. Thomas M'Lean, British Resident at my Court; and it is impossible for me to express my feelings of gratification at the distinction which your Lordship as the President of one of the most useful institutions, has been pleased thus to confer upon me. I cannot however refrain from requesting your Lordship to accept and convey to the Society my sincere acknowledgments on the occasion, as well as an assurance that I shall always feel a lively interest in the prosperity of an Institute, whose researches cannot fail to secure to the rising generation such an improvement in Architecture, as will join the solid simplicity of the ancient, to the ingenious elegance and scientific knowledge of the modern times.

I beg to apologize for the delay which has unavoidably occurred in making this communication to your Lordship; but I was anxious that it should be accompanied by the drawings I had intended to forward, of some buildings which are celebrated in this country for their sculpture. These I do myself the honour of transmitting, with explanatory notes attached to them. But I am sorry that I could not furnish myself with accurate information as to the time when the temples were erected, though most of them are generally believed to be the works of the Chóla dynasty, which probably commenced in the 13th century. Next to the temple of Avidian Coil in point of time, is the Pagoda in the fort of Tanjore; and all I could gather from the inscriptions left upon the base of this, is that it was built in the 1237th year of the Shaleevahen era, or about 522 years ago. I might have added to the accompanying set of drawings, a plan of the bridge lately constructed at my expense by the British government across the river Vinnar, in the vicinity of Tanjore: but I understand that a drawing of it was some time ago forwarded to England for the inspection of the India Board.

I am sensible that these drawings will contribute but little towards the labours of the British Architects: I have only to request that they may be accepted as an earnest of my anxiety to render my services to their Institution.

I have the honour to be
My Lord, your Lordship's
Most obedient Servant,
(Signed) Seevajee Rajah.

Tanjore Palace,
30th Jan., 1838.

The following donations were announced as having been received since the last Ordinary Meeting. Antiquarian Society; Archaeologia, vol. 27.—Owen Jones Esq., Architect; Nos. 4, 5, 6, and 7 of his work on the Alhambra, in gold; and two coloured and gilt casts of ornaments from do.—W. Behns Esq.; bust of the late J. Nash Esq. Architect.—W. R. Hamilton Esq. Honorary Fellow; copy of his address as President of the Geographical Society.—Thomas Walter Esq., Architect, of Philadelphia, U. S.; pamphlets connected with the erection of Girard College in that city.—G. Godwin Jun., Associate; No. 18 of his work on the Churches of London.

C. Barry, V. P. being present, a series of 24 architectural drawings by various masters, and four prints, were announced as having been forwarded to him for the Institute by Sir John Drummond Stewart, who had however died at Paris since they were forwarded. Mr. Barry represented to the meeting that in all his communications with this liberal contributor to the collection, he had ever expressed a lively interest in the purposes and welfare of the Institute.

J. Goldicutt, Fellow, read a description of the mode of transferring some Frescoes painted by Paul Veronese, on to canvass from the walls on which they had been painted; illustrated by the exhibition of the specimens recently imported from Italy.

Thomas Griffiths Esq. commenced his series of papers on Chemistry as applicable to construction.—Introduction;—chemical properties of earthly materials, and their artificial combinations, employed in building.

ARCHITECTURAL SOCIETY.

This closing conversazione for this season, at which the several prizes to the Student Members were awarded, was held at the Society's rooms, 35, Lincoln's Inn Fields, on Tuesday evening, 5th June.—W. B. Clarke, Esq., F.S.A., &c., President, in the Chair.

Several letters were received, from the Earl de Grey, W. Ridley Colborne, Esq., Mr. Alderman Copeland, M.P., and many others, expressive of their regret at not being able to attend, in consequence of absence from town and prior engagements. Mr. Owen Jones, Member, presented Nos. 4, 5, 6, and 7 in continuation of his work "La Alhambra," for the acceptance of the Society. The Secretary then read the annual report; after which the President read a most interesting and appropriate paper; copies of both of which are given below.

At the conclusion of his address, the President distributed the following prizes to the several successful competitors:—

To Mr. Thomas Morgan, Student Member;—for the best measured drawing of the Gateway on each side the Quadrangle of Somerset House;—Sir Wm. Chambers's Civil Architecture, 2 vols.

To Mr. George Rutherford, Student Member;—for the best Essay on the History of the Arch;—Hope's Architecture, 2 vols.

To Mr. George Rutherford, likewise was presented the work annually given by Mr. George Mair, V.P., for the greatest number of approved sketches during the session.

To Mr. William Nunn, Student Member;—for the most approved drawings of the Garden Front of the Travellers' Club House, Pall Mall;—Mr. Owen Jones's work "La Alhambra."

To Mr. G. B. Williams, was presented another copy of the above work, by the liberality of Mr. Jones, in consequence of his merit and that of Mr. Nunn being considered to be so nearly balanced. The President addressed each student at the presentation, on his success; trusting that it would create a greater thirst within themselves and in others to perfect their minds in the various branches of their profession.

The attention of the meeting was then called to a newly invented instrument for the purposes of levelling, &c., by Monsieur Tachet of Paris, recommended from its portability and cheapness.

Mr. R. R. Reinagle, R.A., communicated to the Society the formation of a company for supplying London with water and the formation of fountains in various parts of the metropolis and its environs.

The Society then adjourned until November, when they will again resume their meetings.

ANNUAL REPORT OF THE COMMITTEE.

Gentlemen,—This being the last public meeting of the Society prior to the termination of the present session, your Committee have the pleasure to submit to you notice their annual report, which they are led to believe will be found as favourable as those of former sessions.

The President having announced at the last conversazione, that His Royal Highness the Duke of Sussex had been pleased to become Patron of the Architectural Society, and having then stated most fully the advantages which would consequently arise from so auspicious an event, as well as the renewed energy which this distinguished patronage would impart to every member; it is unnecessary for your Committee again to dwell upon the subject, and they will therefore revert without further delay to a most important point in your transactions;—the annual distribution of prizes to the class of Student Members—a measure adopted for the first time last session.

The Committee cannot but congratulate the Society upon the beneficial results which have already arisen, and are likely to develope themselves from this circumstance; being as it is one step towards the formation of a School of Architecture,—one of the primary objects of this Society.*

The interest arising from the munificent gift presented by the late Professor of Architecture, Sir J. Soane, having been appropriated for the purchase of the yearly prizes,—and the knowledge of his liberality, combined with the cheering encouragement which he always extended towards every department of the Fine Arts,—cannot fail of adding an additional stimulus to the exertions of the competitors; and your Committee have great pleasure in calling your attention to the several drawings and essay compositions, which have this year been submitted in competition. And while they conceive that the labours of those gentlemen will be considered as highly satisfactory, they regret that no competition should have been entered into for the first prize; and they venture to hope that on no future occasion will the Student Members fail to avail themselves of the opportunity thus afforded them of exercising their talents in the class of Design.

In addition to the prizes annually awarded by the Society, the members have to acknowledge themselves indebted to Mr. George Mair for the encouragement he has given to the Student Members, in having announced his intention of giving annually a prize, to that student who shall produce in the course of the session the greatest number of approved sketches, from subjects given by the Sketching Committee.

The members have likewise to tender their best thanks to Mr. Owen Jones, who has most liberally awarded to that student who should produce the most approved drawings of the Garden front of the Travellers' Club House, a gold copy of his interesting work on the Alhambra; and the merit of the competitors for this subject being so nearly balanced Mr. Owen Jones has consequently declared his intention of presenting another copy as a second prize.

To Mr. Charles Barry and the Committee of the Travellers' Club, your Committee beg to offer their grateful thanks for the ready acquiescence with

which the request of your Committee on behalf of their Student Members was received, and for the facilities afforded to those gentlemen in measuring the building.

The Committee are happy to observe that the contributions, both to the Library and Museum, have been as interesting and numerous as the donations received during former sessions; and although the annual report of the Society's finances has not yet been prepared, there is every reason to anticipate that it will be found satisfactory to the members.

The Committee on behalf of the Society much feel the obligation they are under to the gentlemen of the Press for the handsome manner in which they have noticed the conversazioni and the meetings of the present Session. Nor can they close their report, without expressing their thanks to the Visitors who have honoured the Society by their presence on those occasions; and they beg to state that the Society's meetings will be resumed in November next, due notice of which will be given.

PRESIDENT'S ADDRESS.

GENTLEMEN,—I have the honour to address you on the occasion of the second annual award of prizes made by the Architectural Society, with the praiseworthy view of raising a spirit of emulation among its students. The very laudable endeavours of the members of this Society to arouse that desirable spirit of emulation, have met with the most complete success, and the honourable ambition of the students, displayed in the drawings around us, amply testify the ardent desire to attain to eminence in the science of Architecture.

The studies which hang around, and which exhibit in their outline very considerable taste, and in their execution no little patience, will be referred to by these gentlemen with an unmixed pleasure in after years; they will then feel, if they have not already ascertained the fact, that by the labour they have undergone, they have acquired not merely an increased facility of drawing, but a very considerable enlargement of mind by the study of these simple and beautiful architectural combinations. The study of the Travellers' Club, the work of Mr. Barry, cannot fail to enlarge their sphere of taste, and give an excellent direction to their yet perhaps unfixed ideas of architectural beauty and combination in domestic architecture.

The drawings are what are termed geometrical, or presenting every point of the façade to the eye at the same moment. Geometrical drawing is the great means by which the architect conveys an accurate idea of his design, to the workmen who are to carry it into execution. This species of drawing requires extreme accuracy; in default of which the architect must expect his errors to be faithfully executed by his workmen. There are many parts of geometrical drawing which are not always understood by our architects, but with which it is very desirable they should be acquainted. I consider it therefore a duty to point out some of the defects in our knowledge of geometrical drawing, arising in a great measure from our love of effect, indulged to the detriment of a sound acquaintance with the dry but useful details of this art.

The plan, the section, and especially the elevation of an edifice are the subjects to which we principally devote our attention in geometrical draftsmanship, whilst we almost entirely neglect the detail of the drawings; which on a larger scale, should convey an accurate idea of the minutiæ of construction, and most especially of constructive carpentry. As long as objects are parallel in all their parts to the eye, they present no very obvious difficulties in delineating; but when the objects to be delineated are curved, or angular, or polygonal forms, if we are unacquainted with the correct principles and practice of geometrical drawing, we shall be unable to convey the correct ideas of such figures, so as to enable the workmen to execute them accurately.

I have touched upon this subject in order to induce the student to reflect upon the necessity of a more careful study of geometrical drawing than is learnt in the ordinary routine of an architect's studio. In all geometrical drawings however it should be borne in mind, that the simple outline conveying an accurate idea of the form designed should be paramount. The shadows introduced should be projected according to true principles, and the effect should be in an elevation, simple and chaste. By simple and chaste I mean that there should be no factitious shadows thrown upon the edifice, nor artificial aid of landscape to a geometrical drawing. I would even recommend that the imaginary tints of the stone should be omitted; as they tend, especially on a small scale, to interfere with the delicate lines of shade which are produced by your combinations of form. The only artificial aid which I would recommend, should be a slight tint of back ground to give relief to your whole map. The love of factitious shadows and artificial effects, with the addition of landscape, has arisen entirely from the union of the schools of architecture and painting in the halls of the Royal Academy. This union, and the captivating charm of colour which has arisen from it, has unfortunately led to a perverted taste in architectural drawing; our architects endeavouring in their studies rather to emulate the effects of the painter, than to display in simple purity the form and appearance of their architectural combinations. The simple outline was rigidly adhered to by the old masters who combined architecture with painting, and though enabled by their skill in light and shade to produce a striking pictorial effect, they pursued what I would call the right course of geometrical drawing,—that of simplicity and purity.

These great masters also combined with their architectural knowledge, a mastery in delineating from nature, which is rarely acquired even by our greatest painters. The power of drawing natural objects as they present themselves to you, is one which should be carefully studied by the architect; at the same time it is one which is most usually neglected by him. Without this power many an opportunity will be lost, of hastily seizing an idea which in the course of his travels may present itself in the architectural combinations not only of Italy, but of other countries of Europe in which he may pursue his studies. I hold that a knowledge of drawing from nature is absolutely necessary to enable a man to become a first rate architect; without this knowledge he must either copy works already produced, or depend upon the taste of others for a thousand beauties which originate in this power. The student should carefully study drawing from the numerous works in the British Museum, as well as from the ample stores which nature in every shape and form constantly presents to him. Practically, I would recommend the advantages I have derived from tracing objects, combined at the same time with the study of subjects from nature; a course which I have often thought might even render more easy to the learner the art of writing, as tending to fix more accurately in the mind the forms of objects.

I shall conclude this short address by strenuously recommending the student to pursue the study of the many beautiful edifices to be found in this great city; a course which will facilitate his studies in Italy, where with the combined powers of the artist and the architect, he will cull innumerable excellencies from a thousand edifices, and return with a richer harvest of honourable spoils than many who, without these advantages, shall have preceded him.

I need hardly point out, for it is so very obvious, the honourable distinction which the Architectural Society have gained, by the useful course which they have continually pursued from the outset of their career. With humble means, but with hearts earnest in the cause of forwarding the science of Architecture, they have unweariedly pursued their honest way; and it is a proud satisfaction to think that their efforts have been crowned with success;—that the students enrolled in their numbers press forward with enthusiasm, and without a tinge of envy vie with each other in their laudable endeavours to reach the goal and bear away the prize; their greatest desire appearing to be that the most worthy should bear the palm. Let us therefore hope that this generous emulation, so worthy of a virtuous and free people, may produce architects who from their knowledge and taste may reflect honour on the noble country which has given them birth.

ZOOLOGICAL SOCIETY.

AT the late meeting of the Zoological Society, the Rev. F. W. Hope offered some observations on the great havoc committed by the Lymnoria terebrans, upon the piles of the pier at Southend, and exhibited a portion of the wood thus attacked by them. Deal is particularly attacked by this small crustaceous animal, which pierces the wood so that it crumbles, and the pieces are by the abrasion of the water, carried out to sea. It has been usual to char the wood, or case the lower part of the pile with copper; but in this case the animal gets in between the metal and the wood, and the same effect is produced, the piles shortly becoming good for nothing. The attacks of the Lymnoria are found in all parts of England on the coast; and it is now a question of economy whether the use of iron should not be substituted for wood, as the former might easily be protected by any kind of varnish or tar, which will not however consolidate the wood. Many experiments have, however, been made, and are still going on at Liverpool, to endeavour to preserve wood from the attacks of the Lymnoria, Teredo, and other similar destructive species. A member present stated that a great part of the pier at Brighton had been destroyed; and Mr. Clift also mentioned the same of Leith Pier, where almost all those parts of the piles between high and low water mark had been destroyed; those of the thickness of the body, being reduced to the size of the thigh. It had been proposed to preserve them by driving iron nails at short distances, where it was considered that the oxide of the metal would form an enamel that would preserve the wood; but this had no effect. It was also stated that no mode of preparation of the wood by corrosive sublimate, arseniate of potash, or other chemical agents, had any effect towards its preservation.

MEETING OF SCIENTIFIC SOCIETIES.

Royal Institute of British Architects, Monday evenings, July 9 and 23, at eight o'clock. Lectures by Thomas Griffiths Esq. on chemistry as applied to construction, Monday evenings, July 2, 9, 16, 23, at eight o'clock.

LAW PROCEEDINGS.

BAIL COURT. *June 1st.*

THE QUEEN *v.* THE GRAND JUNCTION RAILWAY COMPANY.

Mr. Cresswell moved for a rule to show cause why a writ of *certiorari* should not be issued to bring into this court the inquisition held on the body of a labourer of the name of Hawkins, alleged to be killed by accident. The inquest was held on the 26th January. The jury returned a verdict of accidental death, but that the death was principally attributable to the Merlin and Basilisk engines, upon which a fine of 150*l.* was levied. The peculiarity of the case required that the proceedings should be brought into this court.—Rule granted.

June 7th.

GLASTONBURY *v.* THE LONDON AND CROYDON RAILWAY COMPANY.

Mr. Justice Coleridge gave judgment in this case, which was a motion that a writ of *mandamus* should issue, calling upon the London and Croydon

Railway Company to summon a jury to award compensation to plaintiff for the loss of business he had sustained by that company purchasing the Croydon Canal. Plaintiff was a lighterman, and having taken an average of his profits for seven years and a half, claimed 1,205*l.* 7*s.* 8*d.*, for a period of four years and a half, according to that rate. The judge said that the forty-third section of the company's act of parliament limited the time of application for compensation to six calendar months after the injury sustained; and no notice had been given within the specified time. If plaintiff had been entitled to any compensation it would have been under the 35th clause of the local act, but it did not appear that he was the owner of any land on the line through which the railway was to pass; and as the company was only liable for land or property, it did not appear to his lordship that plaintiff was entitled to any compensation under the act of parliament.

TURNER *v.* THE NOTTINGHAM WATER-WORKS COMPANY.

His lordship also gave judgment in this case. It was a motion made last term for a *mandamus*, calling upon the Nottingham Water-works Company to call a jury to award the plaintiff compensation for loss she had sustained. The jury gave 500*l.*, which the company refused to pay. An application was then made to this court for a *mandamus*, calling upon them to pay the 500*l.* and the costs of the inquest. The court granted a *mandamus* for the payment of the 500*l.*, but refused it for the costs, as there was a legal remedy by distress. But his lordship now thought that as the application was not a joint application, but a distinct and separate one, the defendants might have said, "we will pay the 500*l.* but not the costs." He therefore thought plaintiff was entitled to all her costs; and the *mandamus*, calling upon defendants for the payment of costs, was granted accordingly.

COURT OF QUEEN'S BENCH, *June 7th.*

BURNABY AND OTHERS *v.* THE LANCASTER CANAL COMPANY.

Lord Denman gave judgment in this case. It was an action brought by the plaintiff for the loss of a vessel on the Lancaster canal, by reason of the negligence of the defendants. The plea was not guilty, and verdict was entered for the plaintiffs. The defendants on the occasion got a rule for a nonsuit. The court had heard the case fully argued, and had no doubt but that the action against the company could be maintained. That company had full powers to make their canal safe and navigable: it was a public thoroughfare, accessible to the public for a consideration, and to which even they were invited; and that company had no right to leave that canal in a condition prejudicial to life or property. They were somewhat in the situation of a shopkeeper who invites the public into his shop, but leaves a trapdoor open. The rule, therefore, for a new trial must be discharged.

IMPORTANT RAILWAY DECISION.

An action was lately brought by the Directors of the Cheltenham and Great Western Railway Company to recover from the defendant, Mr. Roberts, the sum of 53*l.* 16*s.*, the amount of shares of which he was the registered proprietor. On the 15th of October, 1836, a call was made for the amount of his shares, which he refused to pay, whereupon the present action was brought, to recover the principal and interest of the ten shares. The alleged abandonment of part of their original line by the company was the ground of defendant's refusal to pay the amount of his shares; but the jury found for the plaintiffs—Damages 53*l.* 16*s.*

Needles.—Messrs. Cocker and Son, of Sheffield, have obtained a patent for, and commenced working, a machine for making needles, which draws out the wire and straightens it, cuts it into the exact length, points it, grooves it, drills and counter sinks the eye, files off the rough edges, and finally drops the needle into a box, at the rate of forty needles a minute. The proprietors expect that fifty machines may be attended by five persons, and that these will produce *one million two hundred thousand needles per day.—Leeds Intelligencer.*

Patent Machine.—A patent machine has lately been set to work at Mr. Charles Todd's weaving factory, Hutchesontown, by Mr. George Smith, of Manchester, for the purpose of starching and drying warps—that is, preparing the threads for the weaver, which is now done by dressing machines. It is capable of thoroughly finishing about one hundred yards of warp in a minute, or six thousand yards an hour, each chain containing about two thousand threads. It is the first erected in Scotland; but they are already numerous and becoming universally adopted in England. —*Inverness Courier.*

Adventures of a Bale of Cotton.—A bale of cotton was shipped on board the Great Western, at New York, on the 6th of May, arrived in King-road on the 22d, was sent to the new cotton factory, at Bristol, on the 23d, and on the 24th, part of it manufactured into yarn, was exhibited, at a public meeting of the inhabitants, as a specimen of the first cotton ever manufactured in that city.

Zinc v. *Tin.*—Mr. Crawshay is said to have sold his extensive Tin Works at Trefforest, Newbridge, to a London Company, who have lately purchased the patent for covering iron plates with zinc instead of tin. Mr. Crawshay himself retains a considerable interest in the establishment, and is one of the directors: his son, Mr. Francis Crawshay, continues the principal manager. Some persons believe that the above patent will produce a complete revolution in the tin trade: time will show — *Gloucestershire Chronicle.*

Fires in London.—The total number of fires observed and reported by the police in 1836, was 240 exclusive of chimneys; in 1837 it was 220. Of these, 104 in the former year, and 59 in the latter, equal to 34 per cent. of the whole number, were extinguished by the police before the arrival of the engines. The estimated amount of loss, generally taken from the statements of the sufferers themselves, was 486,500*l.* in 1836, and 198,550*l.* in 1837. In the former sum is included 400,000*l.*, the estimated loss at the warehouses of Fenning and Co., near London-bridge; and in the latter 150,000*l.*, the loss at Davis's Wharf, at Shadwell. If these two sums be excluded, the loss in the two years amounts to 135,050*l.*—*Journal of the London Statistical Society.*

STEAM NAVIGATION.

Log of the Great Western on the Voyage Home.—The Great Western on her return left New York on the 7th of May. The interest of the citizens was fully sustained to the last moment of her departure. Thirteen steamers started with her, and five of them accompanied her to the Hook. Their decks, the battery, and every point of view, were crowded with spectators, cheering, saluting, and waving flags, &c. We subjoin extracts from her homeward log:—

7th May.—W. 9 knots per hour.

8th May.—Light winds S. 6 knots, wind variable, N.E. Average rate this day, 9 knots. Lat. by observation 48 15 N.

9th May.—Wind light N.W. At 10½ the bearings got warm, stopped a quarter of an hour to cool. At 6 stopped ten minutes to tighten screw of connecting-rod, &c. Average rate this day 7 knots. Lat. 30 34 N.

10th May—Light winds S.W. Average 9 knots. Lat. 39 01 N.

11th May.—Light winds N.N.E., our course due E. At 7 stopped ten minutes to tighten screws. Average 9 knots. Lat. 39 48.

12th May.—N.W. Rate 9 knots. At 5½ exchanged colours with an American standing to westward. Strong wind and variable. Average 9 knots. Lat. 40 10.

13th May.—N.N.E. Rate 9 knots, strong wind and cloudy, with rain. Lat. 40 44 N.

14th May.—E.N.E. Rate 10 knots. Average 9¼ knots. Lat. 41 41.

15th May.—Wind variable, S.E. Rate 10 knots. Average 10. Lat. 43 02 N.

16th May.—Calm, E. 10 knots. At 8 A.M. passed a large ship to westward. Average 9¼. Lat. 44 16 N.

17th May.—S.W. Moderate weather. At 5½ stopped an hour to cool and repair engine crank. At 2½ stopped to right engine. At 3½ proceeded with one engine. Wind variable. Average 9 knots.

18th May.—Strong breeze. At 5 P.M. the brass work being repaired, stopped engine, and set off with both at 55 minutes past 5. Average 9½.

19th May.—Weather moderate, W. Average 9½.

20th and 21st May.—Average 9½.

22d May.—Let go anchor in the Severn at 10 P.M.

The Great Western brought 5,555 letters, and 1,760 newspapers; also a quantity of cotton for the Great Western Factory.—*Bristol Gazette.*

Another Steamer for New York.—The directors met on Tuesday, May 29, and it was unanimously resolved immediately to lay down another steam-ship for the American trade, of a larger tonnage than the Great Western.

Atlantic Steam Navigation.—We understand that the British and American Steam Navigation Company, owners of the splendid steam-ship British Queen, have contracted with our townsmen, Messrs. Fawcett and Co., for a pair of engines 78 inches diameter of cylinder, and seven feet stroke, for their second steam ship, to be called the President, a vessel of 1,800 tons measurement, building expressly for the Liverpool and New York trade, and that the manufacturers have undertaken to put these engines into operation before any others, for the New York line. There is therefore no doubt that the above spirited company will be the first to establish with a line of suitable packets, a regular steam communication with America; and their arrangements are so far advanced for building additional vessels, that there is every reason to suppose, in the course of next year, they will be able to fulfil the intentions expressed in their prospectus (published nearly three years ago), of sailing their packets from Liverpool and London to New York alternately, on the 1st and 16th of each month.—*Liverpool Standard.*

First Steam-Ship from Liverpool to New York.—We have great gratification in observing that Liverpool is not to be left behind Bristol in steam navigation so long as we had reason to apprehend. The spirited proprietors of that splendid vessel, the Royal William, which has performed so many successful voyages, invariably beating her Majesty's steam packets, is under appointment to cross the Atlantic, and will sail from Liverpool for New York on the 5th July.—*Liverpool Mail.*

The New Steamer "The Liverpool."—Great curiosity was lately excited in Dale-street by the passing of a lorry, drawn by five horses, which was laden with what we learned was a paddle-shaft for Sir John Tobin's new steamer "*The Liverpool,*" now lying in Trafalgar Dock. The shaft was of malleable iron, and weighed 6 tons 14 cwt. and 2 quarters, being the largest ever seen in Liverpool; when we observed it, it was being conveyed from the Mersey Steel and Iron Forge, to Messrs. Forrester and Co.'s engineering establishment in Vauxhall-road, where the engines for this gigantic steamer are being manufactured. Some conception may be formed of the steamer from the paddle and shaft in question, which was 23 feet in length, and 18½ inches in diameter; independent, therefore, of the connecting-shaft, the paddle-shafts alone are 46 feet in length; the engine itself struck us as being in size something approaching to that of a village church. We are informed that the engine is 460 horses power, and some single pieces of its machinery, alone, exceed 10 tons weight; a single crank weighs 25 cwt. This engine, and the vessel for which it is intended, are now objects of great curiosity, which has been much excited by the recent successful steam voyage to New York; they are the largest ever manufactured or built in this port.—*Liverpool Mail.*

Great Maritime Steam Projects.—The government has determined to support the communication with the East, by the way of the Mediterranean, Cairo, Cossein, and the Red Sea. But no energy and devotedness, backed even by the wealth of the East, will with the present machinery, which is behind the age, stem the opposing monsoons. It is however as we will show, to be accomplished. It is cruel to exhaust the minds, the thews and sinews of such men as Chesney and Waghorn, and many more, by a pertinacious adherence to antiquated and imperfect systems, solemnly maintained by the assumptive cautiousness of pretended wisdom. The voyage to Alexandria may be expensively performed by boats of the common construction. The monsoons are to be met and overcome, the short head seas to be ploughed through, and the passage made, unerringly, by the means of high-pressure steam only (the safest by far). The other way to India has been determined on. The Azores will be the station between England and the islands of the West Indies. The Portuguese will lease the island required, to the spirited merchants who have commenced the scheme, and there a change will take place of the boats and goods. Perhaps that is not judicious, as it must occupy time, and increase expense, merely to load a different quality of boat. From the Azores, the boats will proceed to the Windward and Leeward Islands; while others go through the river San Juan, from which the obstructions which are few and inconsiderable will be removed, and wend their way through the great lake Nicaragua to the lake, Leon, and thence to Lema in the Pacific, and from thence hasten on to Canton, India, and Australia. Such a line of transit must accelerate the peopling of that fine region which encompasses the lakes, facilitate intercourse with our Eastern and Australian possessions, add value and security to our western colonies, and disperse knowledge, religion, and industry over countries now the haunts of the beasts that graze [illegible]. Another set of men have been carefully building up an undertaking so [illegible] just that it deserves what it will reap—a great reward. They have determined to follow out the plan of that able man, Lord William Bentinck, and establish steam-boats on the great rivers of India, that they may be traversed with the same facility as the rivers of North America. The East India Company, after [illegible] navigation, will not only transfer the boats they have on the Ganges to this company, but afford them their countenance. With liberality, and on principles of sound policy, the natives are to constitute a part of the Indian Directory. The project has been met with open arms by the native and European residents, and we shall soon see the Ganges, the Bramahpootra, and, hereafter, the Indus, transmitting their productions in return for ours; and their thickly-peopled provinces, holding intercourse with realms now almost unknown to them, from the expense and difficulty of travelling. This was a debt due to our vast Eastern dominions. We have before us returns of the numbers who have traversed the Ganges in steam-boats already there, and the accounts of the great demand for transit; and can only say, that the numbers are so great, the amount of produce so much beyond what is generally supposed, that with common prudence the projectors must be enriched, and India greatly benefitted. We understand that the managers intend to avail themselves of all that science can produce, and to combine, at once, the greatest safety and the greatest power. Lord William Bentinck directed that all political correspondence should be carried on in the English tongue. It has led to the establishment of thirty seven colleges or seminaries for the study of the English language,—a matter of state importance; the intercourse being so facilitated, must lead to a wider diffusion of our tongue, and with it its literature and science. If we continue thus to liquidate our debt to India, both will find their reward. Another body of men have a lease, for fifty years, of the Rio Doce in South America, and the exclusive right of navigating that river, which leads from between Rio and the Equator, beyond the Minaes Geraes, into the very heart of the Brazils; so that the commodities of England will be taken by steam craft to the very doors of the inhabitants of the most populous and the richest districts, through regions yet unreclaimed, and where yet the naked savage wanders. The route has been surveyed by the direction of the company. Iron boats are already gone out, with saw mills and other machinery; and an iron steam-boat of 300 tons, is now building, to proceed to that river, and commence the trade. The banks are to receive settlers, and there is every probability of sources of comfort and wealth being opened, which must accelerate the march of civilization, and most probably, sow the seeds of industry and religion in realms where the rarest productions of the tropics spring up, fade, and fall, because there are none to gather.—*British and Foreign Review.*

On Steam Navigation to India: Letter from "Nautilus" to the Editor of the Shipping Gazette.—It is now twelve years since a communication was first effected with India by means of steam. The barque Falcon, which had been previously a yacht belonging to the Hon. Mr. Pelham, now Lord Yarborough, was furnished with paddles and equipped with steam apparatus, destined to enterprise a voyage over the mighty abyss of the Pacific Ocean. Not having been constructed on the same principle as steamers usually are, flat bottomed, she drew her proportionate depth of water, and was as well calculated for going under sailing courses as under the propelling influence of steam; so that she could be considered as having only partially steamed her way out to India. On her arrival at Calcutta she was bought up by the government, her engines were withdrawn, and she was retained as an opium trader between that port and China. The next steamer that came out to India was constructed on the regular plan; she was named the Enterprise, and was commanded by Captain Johnson, R.N. She coasted her route outward, hugging the African shores, touching at the Cape of Good Hope for coals, and reached Calcutta in little better than three months. The sensation produced among the natives on her buffeting her course up a strong ebb tide, in the Hooghly river, her funnel throwing out volumes of smoke, and her paddles re-echoing with crashing reverberations, can be more easily conceived than expressed. It produced a supernatural effect on the credulous children of "Vishnu." This fine vessel of 500 tons was also bought up by the Bengal government, for the purpose of conveying military stores from Calcutta to Rangoon during the Burmese war, in which unfavourable campaign her services were found invaluable. Since that period a dozen or more of steam-vessels of different registers have been constructed in Calcutta, and supplied with engines and apparatus from this country, which trade between the sister presidencies, China, and the Eastern Archipelago. But the most grand undertaking that can be considered under this head, is the steam navigation from Bombay to Suez, as the means of affording a more ready intercommunication between India and this country, which was first performed by the Hugh Lindsay steamer, conveying passengers and packets, about three years ago. The overland course of communication between Suez and the Red Sea was expected to have been attended with many obstacles. It was first contemplated to sink a canal as a connecting gut between the straits of Babel-mandel and the Red Sea; but the sands when agitated by the "kansim" of the desert, it was well considered, would choke up the channel, and render it unnavigable. A railroad was also projected, but then, again, the sand would afford no foundation for such a superstructure; so that the only alternative that remained was to travel over the intervening sandy tracks of desert in caravans. There was another attempt made by Colonel Chesney to communicate with the Red Sea by way of the Euphrates, but the opposition of the north-west monsoons, owing to the torrent floods, rendered the trial abortive. The Tigris was lost in this expedition, so that the only communication between England and India by steam, remains precisely as it began three years ago. Nor indeed is it likely to be improved as to facility of intercourse, though it may be carried on upon, a more extensive scale, so long as the Isthmus of Suez interposes between the two maritime ports. Could the Isthmus be disposed of, or rendered available for the expeditious traffic of large freights, then indeed would the advantages prove incalculably great; but, at present, there appears no more advantageous mode of intercommunication between this country and India than that of the common maritime one, unless steam-vessels of large dimensions were purposely fitted up for that purpose, which even then, when stowage room for coal is considered, would scarcely answer for the reception of large cargo or freight.

Paddle Wheels Exploded.—The latest improvements in Steam Navigation is the patent propeller; it is intended to supersede the use of paddles and paddle-boxes, the unsightly appearance of which is not greater than their practical evils. They are much in the way, and impede the vessel's progress by the resistance they offer.

both to the wind and water. Notwithstanding all the improvements made in them, it has not yet been found practicable to prevent their causing great agitation in the water, nor to work them so as not to waste much of the steam power. The propeller has all the utility and force of the paddle, with none of its disadvantages. It consists, according to the description of the patentee, of an Archimedean screw, and is fixed in the dead wood or run of the vessel. The vessel is shaped and rigged like other sailing vessels, so that the propeller may be used singly, or in conjunction with sails, or not at all, without impeding the sailing, as the propeller may be unshipped at pleasure. Hence the vessel is not solely dependent either on wind or fuel; and long voyages may be performed with great saving, and as the strain of the vessel (so destructive to common steamers) from the engines is much less, so is the wear and tear also. If armed steamers come into use, its application must be invaluable. The arrangement of the engines being fore and aft, gives space on the sides for the introduction of materials for their protection, and the propeller is, from its position, free from gun-shot. In rivers it creates no swell, so frequently productive of loss of property and life. In canals its application would cause no injury to the banks, and the stowage-room is increased by greater breadth of beam. To prove this, an experimental schooner of thirty-four feet has been already built, and fairly tried, both on the river Thames and the sea, with astonishing success. Hundreds have witnessed it, and the pilots of Gravesend and Folkestone can bear testimony to its excellency. The Lords of the Admiralty and several scientific gentlemen have witnessed the performance of this little boat, and have expressed their admiration. She is only thirty-four feet long, six feet six inches broad, and measures six tons. She is so small that her topmasts passed with ease under the paddle-boxes of the British Queen, under one of which she could lie with ease. Yet this tiny vessel—the very smallest steamer, perhaps, in use in the world—towed this great ship up the river, and into the City Canal, to the astonishment, as the papers of the day remarked, of thousands of spectators. If this useful invention realise all which the patentee promises—and we see no reason to mistrust his theory or doubt his experiment—it will be as great an improvement in navigation as the first moving of vessels with paddle-wheels.—*Daily Paper.*

Saint Sebastian Steamer.—On Saturday, the 9th ult., a new steam-vessel was launched from the dockyard of Messrs. Thomas and William Wilson, the builders of most of the boats employed by the City of Dublin Company, and well known for the perfection of their work. This vessel is the first of a line of packets which are to leave Rio de Janeiro twice in the month, with mails and passengers for the ports of Bahia, Parragua, Pernambuco, Ceara, Maranham, and Para, and is called "The Saint Sebastian," in compliment to the city of Saint Sebastian, off Rio de Janeiro.—*Liverpool Mail.*

The Gorgon Steam Frigate.—This vessel, which is the largest and most powerful steam ship belonging to the British service, is just completed. On Thursday, the 14th ult., the engines, which have been made, completed, and fixed on board the vessel in little more than eight months, were set to work for the first time, and acted in the most efficient and satisfactory manner. The tonnage of the Gorgon, according to the old mode of computation, is 1,150 tons; the length of the deck is 183 feet; breadth between the paddle-wheels, 37 feet 6 inches; full breadth of deck, 45 feet. This vessel was built in the dockyard of Pembroke, from the designs of Sir William Symonds, the surveyor-general of the navy, and for her excellent properties as a steam-vessel of war, for her strength, symmetry, and durability, is unrivalled by any vessel in the British or any other navy. She combines also, in a most eminent degree, the necessary qualities of a sailing-vessel with those of a steam-ship. The Gorgon will be fitted with sixteen 32-pounders (long-guns), of which twelve will be on the gun-deck and four on the upper deck. She will also be provided with two of those newly-invented tremendous engines of war, the 10-inch guns, intended to propel hollow shot of 96lbs. weight; one of these guns will be placed forward, and the other aft, on the upper deck, on sliding swivel beds, which will range entirely round the horizon. The bulwarks all round are so constructed that they can be thrown down in a moment to admit the guns being pointed in any direction. The gun-deck of the vessel is fitted up in the most commodious manner for the accommodation of the officers and crew, amounting altogether, with engineers, in war time, to 190 men. The orlop deck, fore and aft, is appropriated entirely for the reception of troops, with their stores and baggage; and the ample hold will receive abundance of water, provisions, and stores for a long voyage. The steam engines for propelling this magnificent vessel are of 320 horses' power; that is, two engines, each of 160 horses' power. They are made by Messrs. John Seaward and Co., of the Canal Iron Works, Limehouse, and are of a very novel construction, being remarkable for their compactness, strength, and lightness. There are four copper boilers for supplying steam to the engines. They are quite detached from each other, and can be used separately or in conjunction, as may be required. This is an important convenience, as it admits of repairs being made to one or two boilers while the others are in use.—*Morning Chronicle.*

Steam to China.—The rage for steam intercourse to all parts of the world is now carried to such a pitch, that we find in the American papers steam vessels advertised to proceed to China.—*Wexford Independent.*

Steam Communication with Ireland.—Steam-boats have done more to cement the union between England and Ireland than all the acts of parliament which have passed since the reign of the second Henry. Agricultural industry in the sister kingdom has received an extraordinary impulse from the opening of new and steady markets, where demand increases faster than supply. The total value of live animals imported from Ireland at Liverpool alone, during the year 1837, amounted to nearly four millions sterling; and the importations to Bristol are scarcely inferior. Mr. Porter, in his "Progress of the Nation," says that the value in money of one seemingly unimportant article, eggs, taken in the course of the year to the above two ports from Ireland, amounts at least to 100,000*l.* The progress of this trade affords a curious illustration of the advantage of commercial localities in stimulating production and equalising prices. Before the establishment of steam-vessels, the market at Cork was most irregularly supplied with eggs from the surrounding district; at certain seasons they were exceedingly abundant and cheap; but these seasons were sure to be followed by periods of scarcity and high prices, and at times it is said to have been difficult to purchase eggs at any price in the market. At the first opening of the improved channel for conveyance to England, the residents at Cork had to complain of the constant high price of this and other articles of farm produce; but as a more extensive market was now permanently open to them, the farmers gave their attention to the rearing and keeping of poultry, and, at the present time, eggs are procurable at all seasons in the market at Cork; not, it is true, at the extremely low rate at which they could formerly be sometimes bought, but still at much less than the average price of the year. A like result has followed the introduction of this great improvement in regard to the supply and cost of various articles of produce. In the apparently unimportant article feathers, it may be stated, on the respectable authority above quoted, that the yearly importation into England from Ireland reaches the amount of 500,000*l.*—*Manchester Guardian.*

Fatal explosions on board the Victoria, Hull steam-ship, and the James Gallacher of Glasgow.—It is with much regret that we have to record another disaster as having happened to that ill-fated vessel the Victoria. On Thursday afternoon, the 14th ult., having nearly finished her voyage from Hull, she ran foul of a collier brig off the lower tier Ratcliff-cross. Both vessels were injured by the shock; the engines of the Victoria were instantly stopped, and in about three minutes one of the boilers exploded with great violence. Several of the men employed about the engines and boilers were killed on the spot; five in the whole were reported as dead the next day; and the latest accounts state that two more have died of the injuries received, besides two others seriously injured. Of eighty passengers, none were materially hurt; one lady only receiving an alarming shock from terror excited by the explosion. Several of the passengers have come forward to acquit the captain of all blame, especially of all design of racing with the rival ship Wilberforce which was within sight during the whole voyage.

On Saturday the 16th ult. an inquest was held on the bodies of the sufferers, and the jury personally examined the boilers. The inquiry was adjourned to Tuesday June 26th with a view of obtaining further evidence, particularly from the surviving but injured engine-men. We shall recur to the subject when the further proceedings and the verdict are reported; meanwhile we give a few of the facts which have been already elicited. And first, the boilers appear to be the same which were originally in use, but repaired since the accident of March 16. In our account of the inquest on that occasion, p. 174, some particulars of their construction will be found. It seems that on the voyage, great difficulty was experienced in getting the steam up; and on the inquest it was suggested that the men had cut off the supply of water in order to effect this object the sooner, and thus caused the accident. This however was strenuously denied by the second engineer, lying on what was expected to be his death-bed. The jury found by the personal examination of one of their number, an engineer, that a rent twelve inches long had been made at the extreme end of the furnace near the flue. The lower part of the boiler was forced outwards and the upper part inwards. From the present state of the bands, it appeared as if the supply of water by the feed pipes was nearly cut off. The jury expressed much surprise at the inconveniently small size of the stoke holes, and wondered how the men could manage the fires in so small a space.

Thursday the 14th ult. was the date also of the other accident which is mentioned in the heading of this article. It occurred at the Railway Wharf near Renfrew, where the James Gallacher had stopped to land passengers. Several lives were lost in this case also; and amongst them, those of some of the passengers. The cause of the accident has not been ascertained

Deeply regretting as we do these lamentable occurrences, we are not inclined on account of them to suppose that the average amount of danger in steam navigation is increasing, as some appear to imagine. For we remember that our steam marine is increasing beyond all precedent;—far beyond the increase of accidents we firmly believe. Still shall we look, not despondingly, but with strict scrutiny, into the causes of such accidents as do occur, and wherever they are traced to faulty construction or negligent working of the machinery, we shall not be tardy in contributing to the torrent of groans which public indignation will pour out upon the guilty. Our Coroner's juries are daily becoming more and more important as courts of inquiry into accidents: we trust to them confidently, to examine carefully, availing themselves of the best professional aid; to judge impartially; to acquit where there is no blame; but heavily to visit those with punishment, whose carelessness or avarice may at any time endanger the safety of their fellow-men.

PROGRESS OF RAILWAYS.

Midland Counties Railway.—There are now upwards of 1,500 men employed on the railway between this town and Rugby, and that number is being gradually increased. A vast number are also employed between Leicester and Loughborough.—*Leicester Mercury.*

Preston and Wyre Railway.—We are happy to be enabled to report that the works on this line of railway are proceeding with great spirit. Of the first contract, from Bourne Naze to Weeton, a distance of eight miles, nearly seven miles have been completed, with the exception of the permanent way, which is now in active progress. On the remaining portion of this contract which is still incomplete, there are about 350 men and between 60 and 70 horses engaged by day and night, and its completion by the early part of autumn is now rendered a matter of certainty. A contract has also been concluded with Mr. Stanton for the whole of the remaining portion of the line from Weeton to its entrance into Preston at Tulketh Brow, a further distance of nine miles, which is to be commenced in the course of the ensuing week. The whole line, therefore, from Bourne Naze on Wyre, to Preston, is now under contract. A fine locomotive engine, of superior construction, was placed upon the railway during the past week, to be employed in conveying ballast and soil between Poulton and Fleetwood.—*Preston Pilot, June 2.*

Lancaster and Preston Junction Railway.—The works belonging to the Lancaster end of this line are proceeding with great activity.

The Manchester and Bolton Railway was opened on Thursday, May 31.

Manchester and Bolton Railway.—We noticed on Saturday, the 9th ult., the numbers of persons conveyed by this railway to and from Agecroft bridge, from this end of the line, during three of the race days. We have since been informed that no fewer than fifteen thousand persons were conveyed to and from the station at Agecroft bridge, during the four race days; and that the transit of this great number of individuals, at a time when, especially in the evenings, there was much intoxication, was effected without the least personal injury being sustained by any one. This was no doubt owing, in a great measure, to the judicious regulation of the railway company, and partly to the prompt and efficient assistance rendered by those officers of the Salford police who were stationed at this end of the line to keep order, a duty which they are stated to have very zealously discharged. The Bolton authorities no less than those of Salford, directed the services of their police to be available on the occasion; and thus, at both ends of the line, notwithstanding the great influx of passengers, confusion and its probable result—accidents—were avoided. The introduction on the line, on Monday the 11th, of open carriages in each train at a lower rate of fare, has been productive of a considerable increase in the number of pas-

sengers during the two following days, the total number averaging eight hundred each day.—*Manchester Guardian.*

Opening of the Newcastle and Carlisle Railway.—Monday, June 26, is fixed for the opening of the whole of this important line of railway between the eastern and western seas. Portions at each end of the line have been in full and successful operation for some time. The middle portion, connecting the two ends, is now completed. The distance (60 miles), it is expected, will be performed in about three hours.

Blackwall Railway.—The first portion of this railway, commencing at the South West corner of Chamber Street Whitechapel and Goodman's Fields, and terminating at the West side of George Street, near White Horse Street Stepney, being a distance of 1 mile and 540 yards, was contracted for on the 19th ultimo. Messrs. George Stephenson and Bidder are the Engineers, and Messrs. Webb the Contractors; there were three other parties tendered. The amount of the Contract is under 60,000*l.* The works comprise the construction of the Viaduct, consisting of 182 arches, varying from 20 to 30 feet span, and 21 Bridges—the latter are principally of Iron. The works are to commence within one month from the date of the Contract, and be completed in 15 months.

Fiddler's Ferry Railway Bill.—The Grand Junction Railway Company, who were the promoters of this bill, have suffered a parliamentary defeat. An adverse division took place in committee, on Tuesday, May 29, the majority 21, and the minority 20; which has led to its abandonment, and under circumstances which, we apprehend, will preclude it from being again brought forward.—*Liverpool Albion.*

Midland Railway.—At recent meetings of the Royal Burgh of Peebles, and of the magistrates and council of the same, it was resolved to use the utmost exertions to promote the carrying into effect of the Newcastle, Edinburgh, and Glasgow Railway, by the Midland line.—*Newcastle Journal.*

Great North of England Railway.—The first stone of the intended Tees Bridge, on the line of this railway, was laid on Tuesday May 22, in the presence of G. H. Wilkinson, Esq., of Harperley Park, chairman of the directors, and the members of the board. The design after which the bridge will be built is of a remarkably chaste and elegant character, and was prepared by Henry Welch, Esq., civil engineer, of Newcastle. The bridge is to be of freestone, and will consist of four arches of sixty feet span each on the oblique line, crossing the river at an acute angle. This circumstance, combined with the extent of the arches, and the materials to be employed, will render this beautiful structure perfectly unique; and it cannot fail, when completed, to reflect the highest credit on the skill and boldness of the architect, and afford a striking illustration of the advancement of science, which can thus triumph over the obstacles of nature, and at the same time pursue the praiseworthy objects of commercial enterprise.—*Durham Advertiser.*

The York and North Midland Railway.—We believe the public generally do not perfectly understand the different lines of railway to which the "York and North Midland" will be united, or of which it will form a continuation. First it connects itself with the Leeds and Selby at Milford; and by using the latter line about five miles, you reach Selby, and will be able to proceed forward to Hull by the Hull and Selby line, which latter place you will arrive at in about two hours from leaving York. At Methley, near Leeds, it joins the North Midland and Leeds and Manchester Railways: by means of the former you will be able either to proceed to Leeds, or travel south to London, Birmingham, Sheffield, &c.; or by the latter to Manchester, Liverpool, &c. &c. And, therefore, all travellers who have occasion to visit York from east, west, or south, can, and most probably will, do so by "the York and North Midland Railway." At this city it also forms a junction with the Great North of England Railway to Newcastle; therefore the only public road of any consequence by which travellers will be deprived of this privilege, will be from Malton, Whitby, and Scarborough. It ought also to be understood that all the traffic on the Manchester and Leeds Railway, going to Hull, which is calculated to be very considerable, will have to travel about seven miles on the York and North Midland line, viz., from the junction at Methley to Milford. We also understand the directors fully calculate on receiving on this part of the line a considerable portion of the present traffic between Leeds and Selby.—*York Chronicle.*

Hull Mail to London.—The directors of the Chamber of Commerce, having called the attention of our members to the application recently made to the Postmaster-General, to expedite as soon as practicable, the Hull mail by the Birmingham Railway, as far as Denbigh hall, &c., and to the reply they had received to that application, from the Postmaster-General; Mr. Hutt has written to Mr. J. Foster, the secretary, that—"At present there is some doubt if the post-office authorities have the power to transmit the mails by railway conveyance, to do away with which a bill has been introduced this session giving a special authority to do so. The bill will be read a first time this day. I understand that no arrangements for the transmission of mails by railway communication will be undertaken by the post-office, till after the bill in question has received legislative sanction. My attention shall be kept to the subject of your letter, and as soon as a proper occasion is afforded, I will call Lord Lichfield's attention to it also. As soon as the bill is printed, I will take care to forward a copy to you."—*Hull Observer.*

The general rate of travelling of the first class coaches on the Liverpool and Manchester railway is now 30 miles an hour; and within the last fortnight the whole 30 miles have been performed in 47 minutes.—*Caledonian Mercury, May 31.*

Railway Fares.—It appears from a statement made in the *Globe*, that whilst the cost of conveyance on the Brussels and Antwerp Railway is only one shilling, the cost of conveyance the same distance on the Liverpool and Manchester line is 6*s.* 4*d.*; on the Grand Junction 6*s.* 6*d.*; and on the London and Birmingham 7*s.*

IRISH RAILWAYS.

[Under this head, we gave in our last number, p. 231, a list of proposed railways furnished by an eminent engineer on whose information we thought, and still think it safe to rely. A correspondent has however supplied us with the following list as more accurate; and we insert it willingly, as our only object is to give our readers full and accurate information. To the last head of the present list, the lines laid down under the direction of the Royal Commissioners, we would direct particular attention, as we have reason to think that our present correspondent has on this subject good means of information.]

RAILWAY COMPLETED.

Dublin and Kingstown - - - - - - Engineer, C. Vignoles Esq.

RAILWAYS IN PROGRESS.

That portion of the Ulster Railway lying between Belfast and Lisburn (distance 8 miles) - - Engineer, G. Stephenson Esq.
Belfast and Cave Hill, commenced but stopped some years ago - - - - - - - - Engineer, W. Bald Esq.

RAILWAYS FOR WHICH ACTS HAVE BEEN OBTAINED.

Cork and Passage - - - - - Engineer, C. Vignoles Esq.
Great Leinster and Munster, or Dublin and Kilkenny - - - - - - - " John Macneill and David Aher Esq.
Dundalk Western - - - - - - " John Macneill Esq.
Dublin and Drogheda - - - - - - " W. Cubitt Esq.
Resident Engineer, G. Woodhouse Esq.

RAILWAY PROPOSED.

Great Central - - - - - - - - Engineer, C. Vignoles Esq.

LINES OF RAILWAY LAID OUT UNDER THE DIRECTION OF THE ROYAL COMMISSIONERS FOR RAILWAYS IN IRELAND.

South and South-western districts.

Dublin to Cork
" Kilkenny
" Limerick
" Berehaven
} Engineer, C. Vignoles, Esq.

North and North-western districts.

Dublin to Armagh
" Enniskillen
} Engineer, J. Macneill Esq.

ENGINEERING WORKS.

River Clyde Improvements.—At no port in the kingdom have such splendid and useful improvements taken place as upon the Clyde, within the last two years. The harbour upon the south side has been proceeded with nearly as far as Springfield works, and the dredging machine has been for some time in constant employment on that side, deepening the bed of the river. Vessels of the largest description that arrive are now stationed there, as a more commodious place for landing goods than on the north. A number of new sheds is at present in course of erection, and three large powerful cranes are daily in operation. But Springfield works seem, for a time, to be the *ne plus ultra* there; and it is much to be regretted that it should be so. Many of the low flat houses by Clyde-place, along the river, formerly occupied by private families, have this year been converted into elegant shops, and vacancies in the streets are fast filling up. The number of steamers is monthly upon the increase. Launches are frequent; and, in the different building yards, all hands are in full employ. Indeed, the traffic upon the river never at any time equalled what it is at present; for, independently of daily arrivals from England and Ireland scarcely a single day passes without a visit from foreign parts. Ere long there will be no necessity for unloading at Greenock, as the largest vessels will find ample harbour room at the Broomielaw.—*Glasgow Herald.*

Rye Harbour.—A meeting of the commissioners of Rye Harbour was held on the 31st of May, at which resolutions were passed to authorise the erection of "a wharf or stages" for the peculiar accommodation of the steam packets about to run between the port of Rye and Boulogne.

Deptford Pier and Junction Railway.—A proposition has been made to purchase this pier and railway to unite with the steam docks, and to commence immediately the excavating for that purpose.

Port Glasgow Harbour.—At a meeting held in the Council Chamber on Thursday the 11th ult., it was agreed that the trust should borrow 4,000*l.*; 3,000*l.* to be expended on necessary improvements at the harbour, but the corporation of Glasgow to be in no way implicated in the debt.

Projected Docks at Sunderland.—The project of constructing docks on the south side of the river Wear at Sunderland is again revived. The scheme at present in view is comparatively limited: it is to make a dock of an area of about three acres, sufficient to accommodate about 35 vessels of the largest size. This resolution has been taken by the advice of two eminent civil engineers, Messrs. Rennie and Walker, together with that of Mr. J. Murray, engineer to the commissioners of the river Wear. The expense is estimated at 45,000*l.*, which it is proposed to raise in 900 shares of 50*l.* each.

Scottish Trigonometrical Survey.—This important undertaking will be shortly commenced, and some officers of engineers have got an order of readiness for this duty.—*Edinburgh Observer.*

NEW CHURCHES.

Plymouth and Falmouth.—New Episcopalian chapels are likely to be built at each of these towns; Mr. Wightwick, Architect, having been applied to by the Reverend Incumbents of livings in each to furnish the requisite designs.

Buckleigh, Devon.—A new body is being supplied to the old tower of the church, under the direction of Charles Fowler, Esq., Architect, of London.

Crediton, Devon.—The church in this town is a singularly fine old edifice, having been once the cathedral of the Western See. Mr. Wightwick is at present engaged in refitting and improving it.

Helleston, Cornwall.—This church is undergoing repairs and improvements, under the care of Mr. Wightwick.

New Church at Holme Bridge, in Almondbury.—On Monday, May 28, the foundation stone was laid for a new church in the above parish.—*Leeds Intelligencer.*

PUBLIC BUILDINGS AND IMPROVEMENTS.

Plymouth.—The public hospital erecting under the superintendence of Mr. Wightwick, is nearly completed, and will shortly be opened for the reception of the invalid poor of South Devon and East Cornwall.

Among the more recent and distinguished of the many improvements which have been for some time carrying on in the same town, is the extensive shop of Messrs. Dabb and Co., Mercers and Drapers; the front extends nearly 80 ft., and emulates in its display of architectural decoration and its splendour of plate glass, the leading shops of the Metropolis. Of this also Mr. Wightwick was the architect.

Ludlow New Public Rooms.—On Saturday, May 26, the Committee of Management appointed to superintend the affairs connected with the new building in Ludlow, met pursuant to notice, for the purpose of finally concluding upon the terms of the contract with the builders, Miss Smith and Mr. Robert Atkins.

The Nelson Monument.—On Saturday, the 16th ult., a meeting of noblemen and gentlemen of the highest respectability took place at the Freemasons' Hall, for the purpose of taking into consideration the best means to be adopted for commemorating the splendid achievements of the late Admiral Nelson. The Duke of Buccleugh presided on the occasion, and was supported by the Duke of Wellington, the Marquis of Anglesea, Lord Lynedoch, Lord Melville, Earl Cadogan; Sirs E. Codrington, George Cockburn, T. Hardy, Richard Vivian, R. Inglis, the Chancellor of the Exchequer, &c. &c. The noble chairman briefly addressed the meeting, and entered into an outline of the objects for which they had been called together. He could not help remarking on the singularity of the fact, that so long a period had been allowed to elapse without any testimonial in celebration of the splendid victories of Lord Nelson having been erected. That fact however having pressed itself on the minds of many distinguished men, had led to the present meeting. The meeting was in the course of the day addressed by Sir E. Codrington, Lord Lynedoch, the Chancellor of the Exchequer, the Duke of Wellington, the Marquis of Anglesea, and others, by whom a series of resolutions was submitted, conveying a strong expression of the warm feeling which pervaded the breasts of those assembled in favour of the proposed object, and their high approval of the site of Trafalgar square, which had been granted by her Majesty's government. A list of donations was received. It contained the names of the Queen for 500*l.*, the Queen Dowager for 200*l.*, the Dukes of Wellington and Buccleugh 200*l.* each, and many others for sums varying in amount.

Wellington Testimonial.—On Monday, May 28, the Wellington Committee met, his Grace the Duke of Wellington in the Chair. With her Majesty's gracious permission, it was resolved to erect an equestrian statue on the arch on Constitution-hill in the Green-park. It is stated that the Wellington statue in the city is to be ten feet high; and the sum in hand for the work, to be about 8,000*l.* Sir J. Chantrey is expected to commence the work immediately.

Monument at Glasgow to Sir Walter Scott.—On Wednesday, May 30, the statue of Sir Walter, executed by Mr. John Ritchie of Musselburgh, arrived. It weighs nearly three tons, is in four pieces, and when put together will stand about ten feet and a half high. The likeness, we are glad to say, is exceedingly good, and the drapery is well executed.—*Glasgow Herald.*

Monument to the late Duke of Gordon.—The sum intended for erecting a monument to the memory of the late Duke of Gordon, in the county of Elgin, is completed, and contractors are wanted for carrying on the structure. This will be the first of the series of monuments to be erected in the Northern counties, in memory of the late Duke.—*Inverness Courier*, May 30.

FOREIGN INTELLIGENCE.

French Railroads.—Towards the close of the sitting of the Chamber of Deputies on Saturday, May 26, the Minister of Commerce brought forward the long expected bills for granting to private companies the authorisation necessary to construct two railroads between Paris, Dieppe, and Havre, by the *plateaux*, and between Paris and Orleans, through Estampes. The clause of the bills precluding all competition during 28 years for the former, and during 25 years for the latter, excited loud murmurs in the assembly. No other railroads can even be established between Paris and any of the intermediate points during those intervals. Some angry observations were subsequently exchanged between Messrs. de Tracy, Martin (du Nord), Lafitte, and Odillon Barrot, respecting the preference given by the Ministry to the company of the *plateaux* over that of the valley of the Seine, and the refusal of Government to authorise the construction of the railroad between Paris and Tours, because in all probability they were to be undertaken by M. Lafitte.

In the Chamber of Deputies on Monday, May 28, the sum of 7,000*l.* was voted in various shapes and forms as encouragements to commerce and manufactures. This the Deputies seem to regard as a princely sum, and make as much fuss about its division as if it were one hundred times the amount. The French government then brought forward its bill for ensuring to the revenue one-tenth of all the sums paid by travellers for their places in carriages on railroads. The commission proposed to exempt for ten years all railroads from the payment of this tax; but the Minister of Finance exclaimed that the revenue of the country could not possibly afford such a deduction, and the Treasury triumphed. One-tenth, not of the net profits, but one-tenth of the receipts is to be taken by the government; and for what? For making, repairing, watching, lighting, paving, or even cleansing the roads? Certainly not. The government is not to contribute to the extent of even one centime to all these expenses, and yet one-tenth of the gross receipts is to be deducted by it. Thus, whilst with one hand the sum of 7,000*l.* is voted to encourage the commerce and manufactures of France, with the other hand one hundred times that amount will, in a few years, be annually taken away by this most terrible tax of one-tenth on iron railways.

On Friday, the 15th ult., the Chamber of Deputies commenced the discussion, and adopted the principal dispositions of the bill for the projected railroad from Paris to Rouen, Havre, and Dieppe (by the *plateaux*), with a branch line on Elbeuf and Louviers. The debate on the measure continued and terminated on Saturday, with the adoption of the bill by a majority of 241 to 52. After the vote on the Paris and Havre Railroad Bill, the chamber commenced the discussion of the bill for conceding the execution of the Paris and Orleans line to Messrs. Casimir Leconte and Co., and up to post hour had adopted the first article, which grants the undertaking to those contractors.—*Shipping Gazette*, June 18.

Railroad from Paris to Belgium.—This railroad excites public attention to the highest degree in the departments of the Oise, Somme, Bas de-Calais, and Nord. The municipal councils of Amiens and Arras have decided that these towns should have an interest in the railroad, the first for 1,000,000 and the second for 500,000 francs; and we understand that the municipal council of Beauvais has adopted a similar resolution.

French Companies.—In one of the French papers lately received, there appears a curious notice about the public companies, for which there has lately been, and indeed is now such a fever in Paris. From this statement it results that in the first two months of this year 67 companies *en commandite* had been registered at the Tribunal of Commerce, with an aggregate capital of 118,022,000 francs, divided into 219,212 shares. Those declared in March, exceeded, however, that of the former two months together in respect of the nominal capital to be employed, the number of shares created being 399,035, with a capital of 274,472,000f. Amongst the associations thus started, the following may be cited as the most considerable:—One for the "mobilisation of the soil of France," with a nominal fund of 10,000,000f.; the Omnium Bank, with 25,000,000f.; Maritime Agency and Transport Service, with 10,000,000f.; Hackney Coach Company, with [illegible]0,000,000f.; Colonization of Algiers, with 6,000,000f.; Bank of Mobilisation and Mortgage Credit Guarantee, with 20,000,000f.; French Bank, with 30,000,000f.; Bank of Industry and Credit, with 5,000,000f.; the Provoyante, an insurance funeral company, with 6,000,000f.; the Financial and Commercial Bank, with 150,000,000f. The total number of companies established since 1826 is stated at 1,106, thus classed:—For periodical publications and bookselling speculations, 401; for trading and manufacturing purposes, 95; hackney and other coach and conveyance companies, 98; mines and ironworks, 60; internal and external navigation, 52; banks and discounts, 40; assurances, 27; draining and cultivation, 25; theatres, 24; miscellaneous enterprises, 280. One of the causes which has chiefly contributed to the spread and rage of these speculations has been the low value of the shares. In many of these companies the shares represent a capital of no more than 4*l.*, 2*l.*, 1*l.* 8s. 4d., and 4s. 2d. each, which places them within reach of every body, and is calculated to tempt the cupidity whilst it imposes on the ignorance of the poorest. To such an extravagance has this frittering of shares been carried, that the shares of a wine company established with a capital stock of 1,000,000f., or 40,000*l.*, were divided and subdivided, so as to catch all tastes and suit all pockets, into coupons of 10*l.*, 4*l.*, 2*l.*, and 1*l.* each.—*Times.*

The French Expedition to the North Pole, is on the point of sailing. The *Recherche* corvette has left Brest for Havre, where it is to stop but a few days. This expedition, which is under the King's special protection, is provided with everything necessary to ensure success, and nothing that could be useful has been neglected. M. Gaimard, president of the Scientific Commission which is to embark in the *Recherche*, has been presented to the King by the Minister of Marine, to take leave of his Majesty, who received him with great kindness, and again conversed with him about the northern regions, which his Majesty has himself visited. The Kings of Sweden and Denmark have desired that their countries should take part in the labours of the French commission, and have added to it men of learning and officers of acknowledged merit.—*Shipping Gazette*, June 4.

Vienna, May 21.—The works on the Emperor Ferdinand's North Railroad are proceeding with great diligence since the fine weather commenced, and there is reason to expect that it may be completed to Moravia, perhaps too as far as Brunn, in the course of the year. The preliminary operations for the railroad from Vienna to Raab are likewise begun. Between Baden and Wienerneustadt the proper direction of the railroad was through a part of the garden of Dornan, the private property of his Majesty the Emperor. The directors, however, out of respect to his Majesty's property, intended to make the roads divert a little from the direct course; but the Emperor Ferdinand being informed of this intention, immediately declared that the road should pass through his garden, and that if any inconvenience should arise, as may happen from an appropriation of this nature, he would submit to them equally with the meanest of his subjects.

Destruction by Fire of the Steam-Ship Nicolai I.—The St. Petersburgh and Lubeck Steam Navigation Company's vessel Nicolai I., Captain N. W. Stahl, was totally destroyed by fire, between 11 and 12 o'clock, in the night of the 31st of May last, with a crew of 33 persons and 132 passengers on board, while on her voyage from St. Petersburgh to Lubeck. The ship caught fire about a mile from Travemunde road. The captain had the presence of mind to run her ashore within one hundred feet of the land, or they must all have perished; as it was, we are sorry to say, that three passengers and two of the crew were lost, also the St. Petersburgh mail bags, together with three carriages, baggage, and other valuable property, have been totally destroyed.

Navigation of the Indus. - The opening of the Indus appears to have given already an impulse to the native trade, and promises to open new markets for British goods in Candahar, Cabul, and Bokhara, as well as Sinde. Some Parsee merchants have succeeded in navigating the Indus up to Loodenah; and this experiment was followed by another, a boat having reached that place from Bombay, freighted with English manufactures, intended for the Punjaub market. A considerable return trade from the Punjaub to Bombay, in sugar, raw and refined, has also recently sprung up. —*Asiatic Journal.*

Enlargement of the Erie Canal.—The bill for the enlargement of the Erie Canal passed the Assembly on Saturday, April 7th. It appropriates four millions of dollars, and contemplates the completion of the work in five years.—*Quebec Gazette.*

The Welland Canal, we learn, is in excellent order and full operation. Numerous schooners and vessels have passed and repassed since the opening of the navigation. —*Quebec Gazette.*

MISCELLANEA.

March of Invention.—Steam Music.—Amongst the numerous inventions which almost daily claim a share of public attention, we have to notice that of a steam organ, invented and adapted to the "Tyne" locomotive engine, the property of the Newcastle and Carlisle Railway Company, by the Rev. James Birkett, of Ovingham. As far as we are able to judge, this instrument bears the greatest resemblance to the organ: it consists of eight pipes, tuned to compass what is termed by musicians an octave, but without any intervening tones or semi-tones. This is the first attempt to adapt a musical instrument to the steam-engine, capable of producing a tune; and though not so perfect as to admit of all the pleasing variety and combination of sound, capable of being produced by the instrument to which we have compared it, there is no doubt but very considerable improvements will be made in this steam musical instrument by the inventor, who is a skilful musician, as well as an ingenious mechanic. We understand that some important alterations are at present in progress, and intended to be completed previous to the grand opening of the railway. —*Tyne Mercury.*

Society for promoting Practical Design.—On Thursday the 14th ult., a deputation of this Society, consisting of Messrs. Wyse, M.P., Hutt, M.P., Ashton Yates, M.P., Hyde Clarke, and George Foggo, had a gratifying interview with Lord John Russell yesterday, to present two addresses to the Queen from the artists of the metropolis and from the society, praying the removal of the Cartoons of Raphael from Hampton Court Palace to the metropolis.

Aberdeen.—Mr. Elsmie, one of the firm of John Duffer and Co., is building a large vessel, one half of the keel of which is iron. It is intended to obviate the want of a flat floor to keep the vessel stiff. She is one of the sharpest ships ever built here; and if always kept afloat, will most likely prove a good sea boat: but should she happen to get logged, there would be perhaps a difficulty in bringing her to the proper steer again.

Coaches leaving London Daily.—From the list of licensed coaches, published by authority of the Commissioners, it appears that 1,476 coaches leave London daily, exclusive of "short stages."

Santorini.—Some tombs discovered in the island of Santorini by M. Bory St. Vincent, give an importance to this island beyond that of its volcanic celebrity. We pass over ruins of temples, cities, cyclopean walls, cisterns, &c., to the account of vases found in some of the ancient tombs, which have been laid bare by the torrents of rain, and so deprived of the mass of tufa, pumice, &c., under which they have for ages lain hidden. One was about sixteen inches high, and nine in diameter, with a narrow neck, the orifice of which was formed of the head of an eagle or griffin; a graceful and light handle was beautifully adapted to the body of the vase; the colour was like that of blood-stone, and apparently, a lynx devouring a stag with branching horns, was designed upon it in black. This was discovered in the least ancient of the tombs (for there are some of much greater antiquity than others, apparently formed by an unknown race), and contrasted in richness of ornament and shape, with the older pottery. This latter is of a hard, sonorous material, full of grains, perhaps sandstone. The largest vase is two feet five inches high, and one foot nine inches in diameter in the middle, and it had four handles; a second had only two handles, and probably contained a provision of grain for the deceased. The stone has not been artificially coloured except with bands of a chocolate brown, and on one side only have been sketched an imperfect meander, circles, zigzags, cranes, &c. &c.; the other side has no ornament, as it was intended to stand close to the wall.—*Athenæum.*

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 26TH MAY AND THE 22ND JUNE 1838.

THOMAS RIDGWAY BRIDSON, of Great Bolton, in the County of Lancaster, Bleacher; and WILLIAM LATHAM, of Little Bolton, in the same County, Machine Maker, for "Improvements in Machinery, and Apparatus for Stretching, Drying, and Finishing Woven Fabrics."—26th May; 6 months.

STEPHEN GEARY, of Hamilton Place, New Road, in the County of Middlesex, Architect, for "Improvements in the Preparation of Fuel."—28th May; 6 months.

THOMAS RIDGWAY BRIDSON, of Great Bolton, in the County of Lancaster, Bleacher, for "Certain Improvements in the Construction and Arrangement of Machinery or Apparatus for Stretching, Mangling, Drying, and Finishing Woven Goods or Fabrics, and part or parts of which Improvements are applicable to other useful purposes"—29th May; 6 months.

MILLS BERRY, of 66, Chancery Lane, Agent and Mechanical Draftsman, for "Certain Improvements in the means of economizing Heat and Fuel in Furnaces, or closed fire places. Communicated by a foreigner residing abroad."—31st May; 6 months.

JOSHUA WORDSWORTH, of Leeds, in the County of York, Machine Maker, for "Certain Improvements in Machinery for heckling and dressing Flax, Hemp, and other fibrous Materials."—31st May; 6 months.

PETER WALKER, of Liverpool, in the County of Lancaster, Brewer for "An Improved Apparatus to be used in cleansing Beer, and other fermented Liquors."—May 31; 6 months.

LUKE HEBERT, of Camden Town, in the county of Middlesex, Civil Engineer, for "A New and Improved Method or Methods of uniting or soldering Metallic Substances."—31st May; 6 months.

GEORGE NUSSEY, of Leeds, in the county of York, Dyer, for "A new Vegetable Preparation applicable to Dyeing Blues and other Colours."—31st May; 6 months.

WILLIAM RATTRAY, of Aberdeen, North Britain, Manufacturing Chemist, for "Certain Improvements in the Manufacture of the Preparations called Gelatine, Size, and Glue."—31st May; 6 months.

EDOUARD FRANCOIS JOSEPH DUCLOS, late of Samson, in the Kingdom of Belgium, but now of Church, in the county of Lancaster, Gent., for "Improvements in the Manufacture of Zinc, Copper, Tin, and Antimony."—31st May; 6 months.

WILLIAM NEEDHAM, of Manchester, in the County of Lancaster, Gentleman, for, "An Improved Machine called the Silkworm, for the purpose of Spinning, Twisting, and Doubling Silk."—31st May; 6 months.

NICHOLAS RAPER, of Greek street, Soho, in the County of Middlesex, Gentleman, for "Improvements in rendering Fabrics and Leather Waterproof."—31st May; 6 months.

THOMAS WALKER, of Birmingham, in the County of Warwick, Clockmaker, for "Improvements in Steam Engines."—31st May; 6 months.

JAMES HARDY, of Wednesbury, in the County of Stafford, Ironmaster, for "Certain Improvements in Rolling, Making, or Manufacturing Shafts, Rails, Fire-iron, and various other heavy Articles of Metal, and the Machinery or Apparatus used in the same."—2nd June; 6 months.

JOSEPH GREEN, of Ranelagh Grove, Chelsea, in the County of Middlesex, Gentleman, for "An Improvement on Ovens."—2nd June; 6 months.

FRANCIS SLEDDON, of Preston, in the County of Lancaster, Machine Maker, for "Certain Improvements in the Machinery or Apparatus for Spinning and Doubling Cotton, Silk, Flax, Wool, and other Fibrous Substances."—2nd June; 6 months.

DAVID CHEETHAM, Jun., of Hollin's Mill, Staley Bridge, in the County of Chester, Cotton Spinner, for "Certain Improvements in the Machinery applicable to the Preparation of Cotton and other Fibrous Substances for the purpose of Spinning."—5th June; 6 months.

THOMAS BECK, of the Parish of Little Stonham, in the County of Suffolk, Gentleman, for "New or Improved Apparatus or Mechanism for obtaining Power and Motion to be used as a Mechanical Agent generally, which he intends to denominate Rotas Vivae."—5th June; 6 months.

SAMUEL BARLOW, of Croydon, in the County of Surrey, Gentleman, for "Improvements in Paddle Wheels, and in commanding Rotary Motion from Steam or other Power, where Change of Speed and Power are required."—5th June; 6 months.

THOMAS HAMMOND FISKE, of Portsmouth, in the County of Hants, Watch and Clock Maker, for "Improvements in Apparatus for Measuring and Indicating the Depth of Water in a Ship's Hold."—5th June; 6 months.

CHARLES KNIGHT, of Ludgate Street, in the City of London, Bookseller and Publisher, for "Improvements in the Process and in the Apparatus used in the Production of coloured Impressions on Paper, Vellum, Parchment, and Pasteboard, by Surface Printing."—7th June; 6 months.

SAMUEL CLEGG, of Sidmouth Street, Gray's Inn Road, in the County of Middlesex, Engineer, for "Improvements in Gas Metres."—7th June; 6 months.

JOHN COOPE HADDAN, of Duke Street, Westminster, in the County of Middlesex, Gentleman; and JOHN JOHNSTON, of Cursitor Street, Chancery Lane, in the City of London, Brass Founder, for "Certain Improvements in Warming, in Lighting, and in Ventilating."—7th June; 6 months.

HERMAN KESSELS, Major in the Belgian Artillery, and Knight of several Military Orders, but now residing in St. Mary Axe, in the City of London, for "Certain new and improved Means or Apparatus for Saving of Lives and Property from Fire, which he denominates 'The Salvator.'"—7th June; 6 months.

ROBERT THOMAS, of No. 86, St. James's Street, in the City of Westminster and County of Middlesex, Boot Maker, for "Certain Improvements in Apparatus to be attached to Carriages, for the purpose of preventing Horses from starting, and for stopping or restraining them when running away or descending Hills."—7th June; 6 months.

EDWARD JOHN MASSEY, of Liverpool, in the County of Lancaster, Watch Maker, for "Certain Improvements in Chronometers and other Time Keepers."—9th June; 6 months.

ARCHIBALD RICHARDSON, of Hackney, in the County of Middlesex, Distiller and Wine Merchant, for "A new and improved Mode of producing a pure Spirit from Malt, and all kinds of Grain, and from Vegetable Substances of every Description containing Saccharine Matter."—12th June; 6 months.

JAMES REED, of Bishops Stortford, in the County of Hertford, Stone Mason, for "Improvements in joining Slate, Stone, and Marble, for Cisterns and other Purposes." 12th June; 6 months.

BENJAMIN LEDGER SHAW, of Henley, near Huddersfield, in the County of York, Clothier, for "Improvements in preparing Wool for, and in the Manufacture and Finishing of Woollen Cloths, parts of which Improvements are applicable to the receiving and stretching of other Fabrics."—12th June; 6 months.

SAMUEL PARKER, of Argyle Place, in the County of Middlesex, Lamp Manufacturer, for "Improvements in Lamps and Apparatus connected therewith."—12th June; 6 months.

RICHARD MARCH HOE, late of New York, in the United States of America, but now residing at No. 66, Chancery Lane, in the County of Middlesex, Civil Engineer, for "Certain Improvements in Machinery or Apparatus for Grinding and Polishing Metal Surfaces."—12th June; 6 months.

RICHARD MARCH HOE, late of New York, in the United States of America, but now residing at No. 66, Chancery Lane, in the County of Middlesex, Civil Engineer, for "Certain Improvements in Machinery or Tools, and Apparatus for chipping, levelling, smoothing, and polishing the Surface of Stone, Slate, or such other Materials."—12th June; 6 months.

HENRY ROBERT ABRAHAM, of Keppel Street, in the Parish of St. George, Bloomsbury, and County of Middlesex, Civil Engineer and Architect, for "New or improved Apparatus for regulating the Supply of Water or other Liquids, and the Quantity delivered into Receivers."—14th June; 6 months.

JOSEPH WINTER, of Fountain Court, Cheapside, in the City of London, Glover, for "Improvements in Painting, Printing, or otherwise Ornamenting the Surfaces of Leather, Silk, Cotton, or Linen, which Improvements are particularly applicable to the Manufacture of Gloves, Stockings, and such like Articles."—14th June; 6 months.

JOSEPH BOLTON DOE, of Hope Street, Whitechapel, in the County of Middlesex, Iron Founder, for "Certain Improvements in Apparatus used in the Manufacture of Soap."—14th June; 6 months.

HENRY DAVIS, of Wednesbury, in the County of Stafford, Engineer, for "Certain Improvements in Engines or Machines to be used for obtaining Mechanical Power, also for raising or impelling Fluids."—14th June; 6 months.

JOSEPH BUNNETT, of Deptford, in the County of Kent, Engineer, for "Improvements in Steam Engines."—14th June; 6 months.

GEORGE PRICE, of Cornhill, in the City of London, Esq., for "Improvements in clarifying Water and other Liquids; communicated by a Foreigner residing abroad." —14th June; 6 months.

RICHARD GOODRIDGE, of No. 7, Bell's Buildings, Salisbury Square, in the City of London, Purser in her Majesty's Navy, for "A new or improved Apparatus for lifting or raising Fluids on Water or on Land, and for Marine or propelling Purposes without Steam."—14th June; 6 months.

JOHN WHITE, of the New Road, in the Parish of St. Marylebone, and County of Middlesex, Architect, for "Certain Improvements in the Construction of Railroad Bridges and Viaducts."—18th June; 6 months.

WILLIAM GOSSAGE, of Stoke Prior, in the County of Worcester, Manufacturing Chemist for "Certain Improvements in Manufacturing Iron."—18th June; 6 months.

WILLIAM GARNETT, of Haslingden, in the County of Lancaster, Dyer, for "Improvements in Machinery, for spinning and doubling Wool, Flax, Cotton, Silk, and other fibrous Materials; communicated by a Foreigner residing abroad."—19th June; 6 months.

WILLIAM EDWARD NEWTON, of Chancery Lane, in the County of Middlesex, Mechanical Draftsman, for "Improvements in Diving Apparatus; communicated by a Foreigner residing abroad."—19th June; 6 months.

JOHN WILLIAM FRASER, of Arundel Street, Strand, in the County of Middlesex, for "Improvements in raising or floating sunken and stranded Vessels, and other Bodies."—22nd June; 6 months.

ELIZA CHATER WILSON, of Skinner Street, Snowhill, in the City of London, Printer, for "Improvements in Evaporation; communicated by a Foreigner residing abroad." —22nd June; 6 months.

NOTICES TO CORRESPONDENTS.

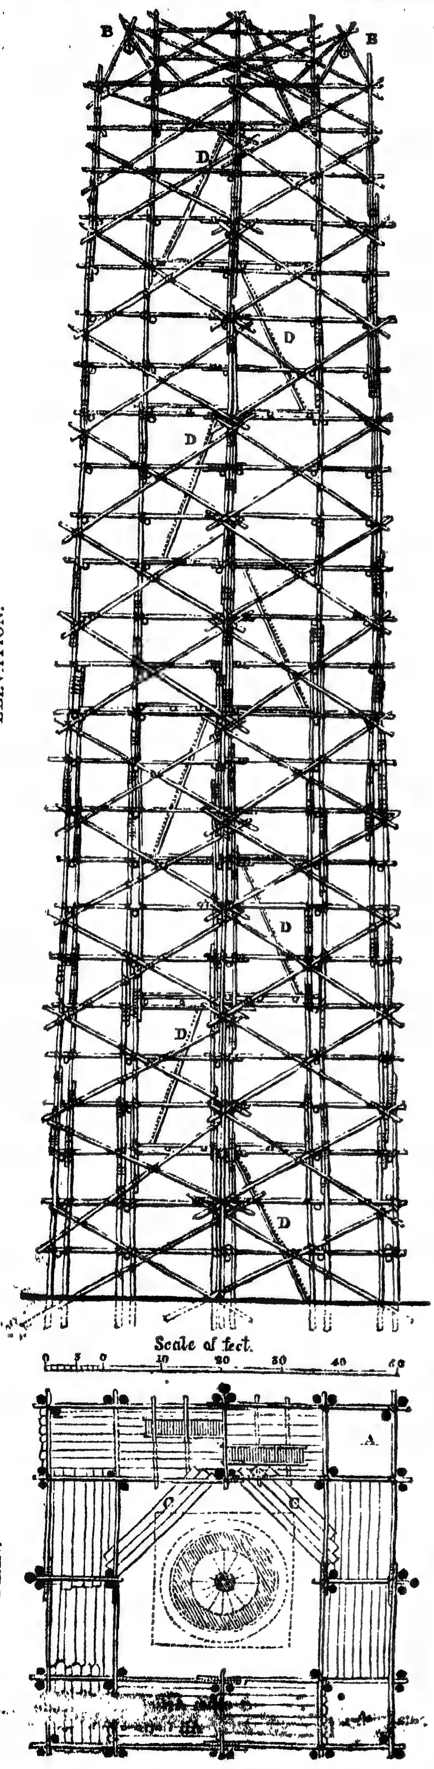
The further notice of Mr Bruff's treatise on Surveying, is unavoidably postponed; as are also several other articles, in consequence of the necessity of publishing the present number several days before the usual time.

The first number of the Journal having been reprinted, complete sets of the work may now be obtained.

ERRATA IN LAST NUMBER.

Page 220, col. 1, line 21, for *Wilkes's*, read *Wilkins's*.
„ 222, „ 2, for *myself to*, read *myself in*.

In advertisement "To Engineers engaged upon Railroads, Architects," &c. for 3s. read 30s., the price of the new machine for taking angles.



SCAFFOLDING USED IN THE ERECTION OF THE MONUMENT.

ELEVATION.

PLAN.

SCAFFOLDING USED IN THE ERECTION OF THE MONUMENT.

The fame of the Monument has spread far and wide; the reader of history is acquainted with it as raised in commemoration of the terrific fire of London; and still as generations pass away, it rears its head conspicuously and attracts the attention of passers by; except indeed of those,—and multitudes they are,—to whom use has familiarized its sight, and who therefore disregard it. Of late years indeed it has missed the shoals of people that used to pour along close by its base, to old London Bridge; and looking down from its balcony at top, it has watched the building of the new and the destruction of the old bridge. Yet the change has by no means tended to throw the Monument into the back-ground;—we beg pardon, the Monument has been thrown into the back-ground, but it has gained greatly by the alteration;—for whereas before it was difficult to find a good view of it in its whole height, since the human neck cannot conveniently turn backwards indefinitely, the new approaches to London Bridge, and the improvements in that neighbourhood, have opened various vistas to it by which it is seen to great advantage.

Yet of the millions that are constantly passing by the Monument,—of the thousands that give themselves the trouble to look at it,—of the hundreds that further take the pains to consider it as an imposing piece of architecture,—and of the tens (principally perhaps professional men) that sometimes picture to their imaginations the times of its construction,—we dare venture to say, units would number those that have ever thought of the *Scaffolding* used in its erection. Indeed we are obliged to our correspondent whose communication is given below, and whose drawing illustrates his observations, for turning our attention to a subject so important, and so little noticed. We do with scaffolding, as with packing cases,—throw it aside when its immediate use is over.

Since Wren's time, the building of obelisks and columns has of course received attention, and consequently important modifications. And,—let us not be thought to descend too abruptly from the grand to the useful,—one totally new branch of building, somewhat similar, has been introduced since those days; the erection of steam-engine chimneys, which in height frequently rival the ordinary run of columns and pillars. In the manufacturing districts too, these are frequently built in a very ornamental style, and are really striking and imposing objects; but for the modern style of chimney, we may refer to a much nearer spot, the Camden Town depot of the London and Birmingham Railway. Chimneys of this kind are now generally erected by means of platforms arranged in the interior.

In our last number, p. 241, we alluded to an ingenious contrivance for building an obelisk without scaffolding, described in the recently published Transactions of the Society of Arts. It was designed by Mr. T. Slacks, Mason, of Langholm in Eskdale, Dumfriesshire, and employed by him in the erection of a monument in that neighbourhood, in memory of Major-General Sir John Malcolm, G.C.B., K.L.S., &c. The obelisk is hollow, with thorough bond stones inserted occasionally for strength. These bond stones were perforated in the centre, to allow free passage for a pole, 40 feet long, passing through three of them and working with a collar of hard wood on the topmost of them, turning freely on friction balls. This pole was furnished with a cross beam at top, having pulleys at the ends, and various ingenious contrivances for raising the materials by means of a windlass below. The pole was raised successively from one station to another as the work progressed; an operation so easily performed as to occupy no more than two hours. The pyramidal apex of the obelisk was finished by means of a hanging scaffold; the pole having been sawn off at the last course before the beginning of the apex, and buried in the work.

The column lately erected at Plymouth to the memory of Nelson, by Mr. Foulston, was likewise constructed without scaffolding. Of this work we hope to be able to learn some particulars; for the present we conclude by subjoining the description of Sir Christopher Wren's scaffolding, furnished by our correspondent.

There is perhaps at the present day no subject on which the attention of the scientific world has been less employed, than the art of constructing scaffolding. Yet in building, there is perhaps no portion which requires more skill and merits more attention to its construction, in order to its effectually answering the purposes required during the progress of the works; especially where they are of so stupendous a nature as that with which we have at present to do.

The accompanying drawings are an exact representation of the scaffolding used by Sir Christopher Wren in the erection of the Monument, [illegible] considered a fine specimen of the art whose claim to [illegible] we have put forward in our previous observations. They consist of a geometrical elevation of one side, and

U

a plan. They are accurately taken from a most ingenious model on the scale of an eighth of an inch to a foot; which although bearing evident marks of its antiquity, remains perfect in almost every respect. It formerly belonged to Sir William Chambers, and was afterwards presented by Heathcote Russel C.E. to Mr. Brunel, Engineer-in-Chief of the Thames Tunnel, in whose possession it still remains: and to his courtesy we are indebted for the accompanying drawings.

At A, A, on the plan, the angles were left free from scaffold boards, for the purpose of hoisting the stone to the shear dericks at the top, shown on the elevation at B, B. Scaffold boards were laid as the work proceeded, across the angles as shown at C, C, on the plan. The whole of the scaffolding was constructed with the ordinary sized poles, reserving the largest for the base. The ladders D, D &c. were of the rude construction of the times of Sir Christopher Wren, formed of two uprights with nailed treads or rounds on the face; and in all cases reaching three stories of the scaffolding.

REVIEWS.

A Treatise on Engineering Field-work: containing practical Land-surveying for Railways, &c., with the theory, principles, and practice of Levelling, and their application to the purposes of Civil Engineering. By PETER BRUFF, Surveyor, &c. London: Simpkin and Marshall, 1838.

(Second Notice.)

In a former number of our Journal, we noticed this work, and promised to complete our review of it by recurring to the latter portion of the treatise, which relates to Levelling. In compliance with this promise, we shall now enter rather fully on the examination of what remains.

Mr. Bruff first explains *The Theory and Principles of Levelling.* Here we must repeat the observation which we made on two of the divisions of the earlier part of the work;—it is far too brief. The work, we apprehend, is not intended for the experienced practitioner, as it exhibits but little that ought not to be already known by every man who pretends to be an engineer. We conclude then, that it has been written for the student; and if so, the author should have entered more fully and minutely into the explanation of the theory and principles of the science. For without these minute points being very fully and clearly explained, we defy any inexperienced pupil to understand the subject thoroughly. Mr. Bruff has given the groundwork for forming an excellent treatise; and we would advise him, if he should be fortunate enough to publish a second edition, to extend the work to at least double the size. As we proceed with our review, we shall very freely point out the deficiencies of the work in its present form, and where by additions it may be materially improved.

Mr. Bruff commences this part of his work by explaining the theory of levelling, and the allowance that must be made for the difference between the true and apparent level, and for the atmospheric refraction. In practical levelling when back and fore sights are taken at nearly equal distances from the instrument, no allowance need be made for either.

But before we proceed further, we must point out the great inconvenience caused by the manner of pointing the decimals which is adopted in this work, and which we have also noticed in others. It cannot be too strongly condemned, as likely to lead to very serious errors in reading and properly understanding the calculations. The inconvenience of which we complain, is the using of the comma (,) for pointing the decimals, instead of the full point (.). We cannot better illustrate the inconvenience than by copying the following sentence from p. 85.

The mean diameter of the earth being nearly 7,916 miles, if we first take B C = 1 mile, then the excess $\frac{BC}{2AC}$ becomes $\frac{1}{7916}$ of a mile, which is 8,004 inches, or 6,670 decimals of a foot, for the distance of the apparent above the true level at the distance of one mile.

It will be observed here, that the thousands of the whole number 7,916 are pointed off with the comma, which, as noticed above, is also used for pointing off the decimals. So that if it were not well known to the contrary, the mean diameter of the earth would appear to be 7 miles and 916 decimals of a mile, instead of seven thousand nine hundred and sixteen miles. Or the excess of a mile might be read in the above sentence, by an unthinking reader, as eight thousand and four inches, instead of eight inches and four thousandths of an inch. It would have been far better to have pointed the numbers thus;—7,916 miles, as in the sentence quoted—and the excess of a mile, 8.004 inches or .6670 decimals of a foot. There could not possibly, with this pointing, be any error committed by a person acquainted with decimals. Again in p. 157, where the author is treating of the method of calculating earth-work, another serious difficulty occurs from a similar cause; 128.795,6180 is given as the number of cubic yards in an embankment. Here the full point and the comma appear to have changed places; we suppose it to mean 128,795 cubic yards and 6180 decimals of a yard. But by the method of pointing generally adopted, it would be 128 cubic yards, and the remaining figures would denote decimal parts of a yard.

The next portion of the work is *The Practice of Levelling.* The author first describes the nature of the *datum* line; he next explains the method of obtaining the difference of level between two or more points by fore and back sights; and afterwards gives an example, being part of a contract section taken for a railway. Extracts are subjoined from Mr. Bruff's field-book, of which we give a short example.

Elevation.	Back Set.	Fore Set.	Depression.	Total Rise.	Distance.	REMARKS
				80,96	B.M.	Height above Trinity Datum. Level of ground at B.M.
1,11	6,84	5,73		82,07	0,00	
	5,73	8,10	2,37	79,70	,15	
	8,10	8,15	,05	79,65	,45	
2,35	8,15	5,80		82,00	,50	
,80	5,80	5,00		82,80	1,10	
,45	5,00	4,55		83,25	2,17	
,96	5,01	4,05		84,21	2,60	
	4,05	4,98	,93	83,28	4,00	
	4,98	6,12	1,14	82,14	5,00	
	6,12	6,67	,55	81,59	6,00	
	2,25	7,77	5,52	76,07	8,00	
	7,77	13,52	5,75	70,32	10,00	

The method of procedure in setting down, casting out, and reducing the levels in the above form of field book, will be easily understood on reference thereto. In the second and third columns are entered the back and fore sights, opposite to each other: the first contains the difference of the two, if a rise; if a fall, it is entered in the fourth,* the differences in this form being set down in the order they are cast out. The fifth contains the reduced levels, obtained by adding or subtracting the differences to the previous reduced level; the sixth the distance (which will be perceived is continued from the commencement to the end of the section); and the last, which is the largest, for remarks, to note the crossings of roads, rivers, brooks, &c., and, if necessary, to enter the bearing of your line of levels; but in the above case no bearings were taken, as the ground had been surveyed, and the line definitely marked out. * *

The sketches of the crossings of roads, rivers, &c. in the fifth column need no explanation; they are plotted to a large scale on the section, and will be found of infinite service to the engineer in guiding him as to the dimensions of his bridges, so as to maintain a proper width of roadway, &c.

The above example of a field-book comprises all the data requisite or necessary for drawing a contract section, for which purpose it was taken. The levels are based on Trinity datum, which was previously ascertained, and bench marks left at each end. * *

The plotted section from the above field-book is given at the end of this treatise, by referring to which, and carefully looking over the field-book, the student will become perfectly acquainted with every particular necessary for the purpose.

In the above field-book it will be observed that Mr. Bruff does not number his stations; this we think ought to be done in all cases, and we find it particularly serviceable for referring to the bench marks and fences, and also for reference when a cross section is taken. Neither is there a column for *total depression,* which we consider indispensable; for in levelling a long line of country it is frequently necessary to employ several surveyors, each with different datum lines, which must afterwards be re-adjusted to one general datum line. We have found in practice that the surface line of the country sometimes comes below as well as above the datum line. We also prefer taking the distances from station to station, and afterwards adding them together as shown below in the subjoined copy of a portion of one of our own level-books. This we consider decidedly a better plan than Mr. Bruff's, and it is adopted by many others besides ourselves.

* When the difference of columns 2 and 3 have been cast out, the four columns should always be added up at each page, previous to reducing or carrying the difference to column 5; the total rise or fall will correspond, if correct; the reduced level must also correspond by deducting the quantity brought forward at the commencement of each page.

Number of Station.	Distance.	Total Distance.	Back Station.	Fore Station.	Rise.	Depression.	Total Rise.	Total Depression.	Observations.
1							4·00		No. 1, top of step at the junction of Roads above Trinity Datum.
1—2	440		6·80	6·67	0·13		4·13		No. 2, corner of Bond-street.
2—3	1200	1640	5·75	5·45	0·30		4·43		No. 3, opposite No. 10.
3—4	366	2006	4·70	4·72		0·02	4·41		No. 4, centre of Bond-st. & Miles-st.
4—5	570	2576	3·50	8·54		5·04		0·63	No. 5, centre of T. rd., Cross Station A.
5—6	160	2736	5·26	4·60	0·66		0·03		No. 6, op. Road leading to Windmill.
6—7	600	3336	6·46	8·35		1·89		1·86	No. 7, opposite Wharf.
7—8	300	3636	4·81	3·65	1·16			0·70	No. 8, opposite Factory.
8—9	510	4146	4·36	3·25	1·11		0.41		No. 9, opposite Brewery Gate.

It will thus be seen that our level-book has three additional columns when compared with that of Mr. Bruff; and all these we consider indispensable.

Mr. Bruff next proceeds to give some brief directions for proceeding with the levels, and remarks :—

——that it is always preferable to use one staff only, on account of the difference of the graduations, although made by the same person with ever so much care. We have frequently, when adjusting our instrument, found a difference of $\frac{1}{100}$ of a foot in the readings of two staves, although made by the same person, and no doubt the errors are often much greater. To avoid this source of error, we would always advise the use of one staff in preference to two; as in the latter case there is very little, if any, time saved, an additional expense incurred, and the chances of error greatly multiplied.

Here we must differ from Mr. Bruff; as we think that his remedy is far worse than the evil. Suppose there be a difference of $\frac{1}{100}$ of a foot in the reading of the two staves;—it will be rendered nugatory in a continuous line of observations, as the *two* staves become alternately the back and fore stations, and consequently compensate each other. We consider two staves so very requisite, that we would never recommend a line of levels to be taken without them. Nor would we on any account allow the back staff to be removed, until the sight of the fore staff is taken and entered, and the instrument re-examined to see if it remain in proper adjustment.

In the next section, the utility of *Bench marks* is explained; and in several following ones it is shown in what manner *Trial levels, Check levels*, and *Cross sections* are made, and for what reasons recourse is had to each.

The next chapter is *On Chaining*, explaining "the methods of passing woods and rivers, and overcoming difficulties that occur in levelling;" which contains some useful hints relating to these operations. In a section on *Levelling with the Theodolite*, after having given some explanations and examples, the author observes :—

The above method of levelling with the theodolite, may be advantageously adopted in taking trial sections for crossing summits—one section should be carefully taken with the spirit-level, the remainder may be taken with the theodolite—vertical angles being measured to the bench-marks at the extremeties; any errors that may have crept into the calculations will then be detected.

If this plan was adopted, how much expense would be saved; comparative sections may then be taken in every direction without the enormous expenses incurred by the present method. Such correct results may not be arrived at certainly as with the spirit-level, but in these preliminary sections, of what consequence is the differing a few feet, when perhaps the *crossing of a summit may be effected thereby at a less elevation by ten times the amount of error.* The theodolite is not put in comparison with the spirit-level for accuracy, but for the above purposes, where a near approximation is all that is necessary, it is presumed it will be found a far more advantageous instrument, as, in some districts, the surveyor might do ten times the quantity of work as with the spirit level.

In his observations *On the choosing of a Datum Line*, Mr. Bruff appears to prefer taking the level of low water spring tides as a datum; and he states that it is considered more equable, and is now generally taken by engineers as their datum line. We feel disposed to differ from the author on this point; and we consider high water spring tides preferable for a datum line, as giving at a glance a good idea of the possibility of obtaining a good drainage for the country when intersected by embankments or excavations. For if at any point on a railway line, you find an elevation of from three to four feet per mile above high water mark of the river or sea from which you have set out, you may generally calculate on being able to obtain a good drainage; but this will not be so readily seen if the low water datum be adopted. For extensive operations, Mr. Bruff advises

—— the mean level of the sea to be taken; which (according to M. De la Lande's method, and adopted in the Trigonometrical Survey of England) may be obtained by taking the level of low water, and deducting therefrom one-third of the height to which the tide rises.

The work proceeds to treat of the different *Instruments used in Levelling*, with their various adjustments. Under the head of *Levelling Staves*, the author explains an improvement contrived by himself, which appears to us worthy of notice.

A staff has been contrived by the author, which will be found more convenient than any that has appeared before the public; one great fault with the improved staff is, that in reading off with an inverting telescope (which nearly all levels have now, for reasons before explained) you are very liable to error from the figures appearing upside down, you are consequently apt to mistake one figure or division for another, often leading to serious errors. To remedy this inconvenience *the figures on this staff are inverted*, whereby, when viewed through an inverting telescope, they appear in their natural order, doing away with the confusion and uncertainty hitherto existing, and enabling the observer instantly to note the reading with expedition and accuracy, altogether making a considerable difference both as to the quantity and accuracy of the work.

There follow sections *On the setting out of Railways*, on the *Manner of putting in the Widths*, and *On Gradients*, &c. &c., containing some useful remarks and directions.

Appended to the work are several drawings of Plans and Sections illustrating it, and rendering the whole more readily understood.

What Style? The Royal or Baronial? The Priestly or Monastic? Or the Squirely? For the New Houses of Parliament. By ARCHILOCHUS. London: T. and W. Boone. 1837.

Having never heard of this pamphlet, nor seen it advertised till very lately, we imagined it to be but just published, whereas it bears the date of 1887. If this be an error of the press, it is a very strange one, —yet not at all more strange than the pamphlet itself, for though we have patiently read it through, we must confess that we do not comprehend it. It looks as if it were intended to be particularly witty, yet whether it really be so must be decided by those who can make anything at all out of it. We very much question, however, whether it be in the power of any one to do so, except Archilochus himself.

Whether or for what purpose this unintelligibleness is assumed, we know not; but after the two or three first pages, which are written intelligibly enough,—so much so that we hoped to be able to gather something from the writer's remarks; he plunges into such downright extravagance that we cannot even guess what he would be at—what it is that he would recommend, or what he actually objects to. To such extent is mystification carried, that in the pretended account of the discussion between the Commissioners, the initials of their names are said to be R.J., A.T., G.P., T.W., and P.P. Now if in order to avoid the appearance of personality, the writer had chosen to give fictitious or burlesque names, there would have been nothing very unintelligible in that; but that he should give false initials where the names themselves are no secret, is quite inexplicable. He might just as well at once have substituted Pam for G. P. as speak of "G. P., the subtle orator, who went by the name of Pam." Among a great deal of other stuff, this oratorical gentleman is made to say, "The new surtout in which Windsor Castle has been dressed, that happy thought of a warlike front without the means of offence and defence, though it has removed all associations of the sovereigns prior to George IV., and stands by its style a monument of obedience to those two commandments, and of that monarch's peculiar good taste;" to which is added "and there was a kind of catch among the committee, of Great King, Pious Prince, Gusto, Gusto!" There is page after page in the same exceedingly funny strain—for funny, we presume it is—at least meant to be so, though it puzzles us to conceive that there is any meaning at all. For aught we can tell Archilochus may be a very clear-headed fellow, and has only put himself into disguise: but it is rather too bad in him to make his readers feel quite bewildered and muddy-headed over his pages. Why any one should take so much pains as Archilochus does, to act the Sphynx, is to us a perfect mystery.

Project for a National Gallery on the Site of Trafalgar Square, Charing Cross, Proposed and Designed by Joseph and John Sebastian Gwilt, Architects. [Not published.]

We have not been favoured with a copy of this unpublished "Project," and therefore know no more of it than what we are told by the "Literary Gazette," which has been so distinguished. Our only reason for regretting that we must speak after the report there given, is that we are at the same time deprived of a sight of the design, which judging from the title, we presume accompanies the No-Publication. To be sure the words within brackets generally operate as a strong provocative to curiosity; but the Gazette has quite satisfied our curiosity as to the main point, namely that Mr. Gwilt's

—we beg John Sebastian's (qr. *del piombo*) pardon—Messrs. Gwilt's design is likely never to appear before the public at all;—that is, if it is forthcoming only when called for,—because a more preposterous scheme than their project has hardly ever been seriously brought forward; and that is saying a great deal considering what heaps of *moon*-shine have been brought to market by projectors and speculators.

Messrs. Gwilt, with the most graceful modesty imaginable recommend their new Design to be carried into execution, and a building erected from it—where?—why, on no other spot of ground within the Bills of Mortality than Trafalgar Square itself, they having discovered that it is "an enormous vacant area of no utility." It is a monstrous pity Mr. Joseph Gwilt was not enlightened with this idea some years ago when there was so much bickering in the papers relative to the site chosen for the National Gallery; and in which he himself took so very active a part. Had he stepped forward with such advice then, he might perhaps have had the credit of being actuated by professional zeal and public spirit; whereas to make the suggestion now, looks very much like malice and officiousness.

What has become of Mr. Joseph Gwilt's anxiety for St. Martin's Church, which he was then of opinion ought to be as much exposed to view as possible?—whereas he would now quite screen it again, by clapping an extinguisher upon the Square itself. It must be admitted that the case would be somewhat altered; because although had Mr. Wilkins brought his building as far forward as he originally contemplated, the portico of the Church would have been partially hidden from Pall Mall East; there ought to be no objection to allow the Gwilts, Joseph and John Sebastian, to shut it out from view entirely, in regard to Cockspur-street and Charing Cross.

Even such an idea is exceedingly modest; yet perhaps not at all more so than the opinion expressed of the Design itself. "A building," we are told, "three hundred and forty feet in length, rising to a height of eighty-one feet (being three feet higher than the Banqueting House at Whitehall), of extreme simplicity in its general form and detail, will at all events form a feature to which all the objects within the range will be subordinate;"—St. Martin's therefore, of course as well as the rest. This is positively startling, for we here find the Gwilts' proposing to render that church and everything else secondary to their own design, and to overpower it by the height and mass at least of *their* National Gallery; for as to decoration, that they seem to disclaim. The building they contemplate is to be marked by "extreme simplicity," and fully sure are we that the plan is characterised by extreme simpleness.

One of the allegations against Mr. Wilkins' building is, that it is considerably too low; yet we very much question whether Mr. G. would not have inveighed against it quite as furiously as he now does, had it been much higher: for he would then have protested against it—perhaps have likened it to a "tall bully," on the ground of its making his favourite St. Martin's look, if not fowl, at any rate *fish* by comparison,—videlicet quite *dwar-fish*. It appears to us that extent of length not of height best befits the character of a "Gallery," both internally and externally; so that what is censured as a defect, may as justly be applauded as a propriety. Were the rooms much loftier, either the upper part of the walls must be left blank, or else a great number of pictures put out of sight,—hung up so as to be ornamental furnishings, but not so as to be properly viewed and studied. It must be admitted that the Sebastian del Piombo would be seen to greater advantage in a room a few feet higher; but taking the collection generally, the rooms are quite lofty enough for the paintings. But it is urged that although it may answer its purpose just for the present, the building is utterly inadequate to receive such a collection as ought to be formed. We do not dispute this; yet we consider it neither an imputation on the architect (who was limited to a narrow slip of ground); nor irremediable in itself. On the contrary without adopting the suggestion of the Literary Gazette, either to pull down the Gallery or convert it into Barracks, all difficulty might be got over at once by the site of the adjoining barracks being given up for the extension of the Gallery. It is so spacious that by covering it with buildings around a court, the present size might be nearly quadrupled; besides which another quadrangle surrounded with galleries might be added at the West end of the edifice, behind the houses in Pall Mall East; as shown in the plan given in the Report of the Select Committee on Arts &c. Such additions may at any time be made with equal facility and economy; because as the buildings so situated would be completely shut out from view, the external walls would require to be only plain brick, without any ornament or finish whatever.

The idea of taking the National Gallery down is so extravagantly preposterous that we can hardly imagine it to be seriously entertained for a moment even by those who have not scrupled to propose it. If deficient in spaciousness within, what has been erected is at least a façade, the building behind which may be extended as circumstances shall require, and certainly much more economically than by beginning entirely *de novo*. If too the façade itself be not exactly what could be desired, it is capable of being finished up, and otherwise improved without greatly disturbing the design as it now is. After all, whatever we may think of the Gwilts' modest scheme, we do admire the prudence or forbearance which withheld them from exhibiting their own design at the Royal Academy. Such modesty however is neither valorous nor virtuous; least of all public-spirited; inasmuch as, we venture to say, it has robbed the public of—a hearty laugh.

Proposed plan for improving Dover Harbour, by an extension of the South Pier Head &c.: also, copious extracts from various Authors in support of the Plan, and showing the importance of Dover Harbour from the time of its first construction. By Lieut. B. Worthington, R.N. Dover: 1838.

The importance of Dover Harbour in a national point of view, will be disputed by none; its proximity to one of the most powerful empires of Europe has rendered it famous from the earliest periods of our history, whether in times of peace or war; and the closer become our relations with our continental neighbours, the more completely will the Straits of Dover serve as the highroad of our intercourse, especially when those great lines of railway shall be completed, which are designed to connect London with Dover, and Paris with Boulogne or Calais. As an engineering work too, the improvement of the harbour is intimately connected with the objects of our Journal; and the two considerations combined, appear to demand from us more than ordinary attention to the subject. We shall therefore enter minutely and critically into an examination of Lieut. Worthington's suggestions; acting in the spirit of his chosen motto, we shall

——— "nothing extenuate,
"Nor set down aught in malice,"

and in doing so, we are sure he will allow us the liberty of freely commenting on his proposals. For we have both at heart the same object;—to endeavour to awaken public attention to the necessity of keeping this valuable harbour in a state of efficiency, and of extending as far as possible its public utility.

Lieut. Worthington has collected together a great mass of useful information connected with Dover Harbour, for which the public is deeply indebted to him; for this is the only way by which a right understanding can be arrived at, respecting the best mode of improving the harbour. He commences by giving various extracts, showing "the state and importance of Dover Harbour." The first of these, from "a memorial presented to Queen Elizabeth, by Sir Walter Raleigh, Knight," is so much to the purpose, and by its expressive language condenses into so small a compass such weighty considerations showing the importance of the harbour, that we cannot do better than give the whole.

"No promontory, town or haven, in Christendom, is so placed by nature and situation, both to gratify friends, and annoy enemies, as this town of Dover; no place is so settled to receive and deliver intelligence for all matters and actions in Europe, from time to time; no town is by nature so settled, either to allure intercourse by sea, or to train inhabitants by land, to make it great, fair, rich, and populous, nor is there in the whole circuit of this famous island any port, either in respect of security and defence, or of traffic or intercourse, more convenient, needful, or rather of necessity to be regarded, than this of Dover, situated on a promontory next fronting a puissant foreign king, and in the very streight, passage, and intercourse of almost all the shipping in Christendom."

"And if that our renowned King (Henry 8th), your Majesty's father, found how necessary it was to make a haven at Dover (when Sandwich, Rye, Camber, and others, were good havens, and Calais also was then in his possession), and yet spared not to bestow, of his treasure, so great a mass, in building that pier, which then secured a probable means to perform the same; how much more is the same now needful, or rather of necessity (those good havens being extremely decayed), no safe harbour being left in all the coast almost between Portsmouth and Yarmouth. Seeing, then, it hath pleased God to give unto this realm such a situation for a port and town, as all Christendom hath not the like, and endowed the same with all commodities by land and sea, that can be wished, to make the harbour allure intercourse, and maintain inhabitants; and that the same once performed, must be advantageous to the revenue, and augment the welfare and riches of the realm in general; and both needful and necessary, as well for the succouring and protecting friends, as annoying and offending enemies, both in war and peace; methinks, there remaineth no other deliberation in this case, but how most sufficiently, and with greatest perfection possible, most speedily the same may be accomplished."

The following extract from the Archæologia, vol. xi. p. 241, is on of great importance.

STATE OF DOVER HARBOUR BOTH BEFORE AND SINCE THE BUILDING OF THE PIER, WITH THE ALTERATIONS MADE BY THE BEACH, AS IT IS FOUND BY THE EXAMINATION OF THE MOST SENSIBLE, ANCIENT, AND SKILFUL MEN, BY DIRECTION OF THE LORD ADMIRAL OF ENGLAND, BEING AT DOVER, DEC. 21st. 1581.

"Before the pier was built out, there are men alive can remember that there was no banks or shelves of beach to be seen before Dover, but all clean sea, between Archcliff tower and the Castle cliff."

"By experience it hath been always found that as the pier was built out, so the banks of beach also began to grow, and lay farther out as the pier was farther built, and as the pier hath decayed, so these banks of beach also have been either scoured away, or driven farther in, and that those banks of beach never rest farther forth into the sea, then they are defended by the pier."

"Also it is found that the making of groins will ever encrease the quantity of beach, and the decay or pulling down those groins, doth also cause the same bank of beach to wear away so far forth as the groins are built or taken away."

"Also it is found that the abundance of beach is so great as they cannot be stayed by any groins, but that they will fill the groins, and then go about them, holding on their course as the flood carries them."

"Also that there is no other entrance or haven mouth at this present, but such as the ebbing out of the sea water, and course of the river do keep open."

"It is also found by experience that the same mouth or entrance doth always grow nearer and nearer towards the town; and that in times past it hath grown so near, that by the violent rage of the sea, passing through the same, a part of the town itself hath been in danger to be overthrown."

"Also it is found, that the beach hath, and doth increase still more and more, under and beyond the Castle."

"Also that lately where five rods of bavin work have been made up of the broken pier, the beach is also grown out to the end thereof, and so groweth down from thence lower and lower towards the town-ward."

"Also it is found that the great rocks that were sunken by king Henry VIII. do still lie there, and are not removed by any violence of sea, but by the wearing of them, or looseness of the ground under them, have sunk somewhat lower and lower."

"Also it is found that part of the pier standeth on a firm rock of chalk, and part on a soft soil."

"Also it is apparent at this present, that where the beach and ooze are incorporated together in a main shelf, it so retaineth the water inclosed within the same, towards the cliff, that there is ever a long standing pool of water, twelve feet at least higher than the sea without at low water."

It is surprising that with such a document before them, Lieut. Worthington and others should have committed the error, which to us they appear to have done, of recommending the extension of the pier head, or the formation of a breakwater. We consider that the whole of the so-called improvements that have been carried on, consisting of successive extensions of the pier, have been the cause of the formation of the *bar* at the mouth of the harbour. We shall however enter more fully into this part of the case below.

The author gives a great variety of other extracts from official and other documents of various periods from the reign of Henry VIII. down to the present times, showing the various states of the coast, and embodying the recommendations of different engineers who have been employed from time to time to report on the improvement of the harbour. Most of these recommendations consist of the proposal to extend the South pier head. Mr. Ralph Walker in his report of 1812 recommends that,

"———— the *south pier head should be extended out as far as low water mark*, which would be the means of carrying the beach into deep water, and increasing the velocity of the flood stream round it, and would tend much to carry the beach *past the entrance*, and whatever might be deposited there by the flood tides would be more exposed to the currents of the reflux of the tides, as they would not be deflected without it by the north pier-head; and if the culvert or tunnel proposed by Mr. Moon should be adopted, and carried out through the pier from the outer pent, I am of opinion that it would be of great advantage in scouring away the beach, not only at the times of low water, but also to draw the sluices off a little before low water at the times of spring tides when there would be abundance of water. I am aware it may be said, that the beach carried away then would be brought back with floods and westerly winds, but let it be kept in mind that by being carried further out into deep water, *it will be carried past the entrance before it could reach the shore.*"

The Lieutenant next proceeds to furnish a variety of extracts from evidence given before a Committee of the House of Commons appointed to inquire into the state of Dover Harbour. The evidence fully proves that the South-west winds are the cause of the formation of the bar at the mouth of the harbour. The following is from the evidence of the Hon. Captain George Elliot, R.N.

"[Ques. 1922.] The effect of the two piers, as at present constructed, is to act as it were *by suction* on the shingle, and to draw the beach into the harbour?—I think there are several things relating to the two piers, and more particularly to the western pier, which I should like to explain my feelings upon. The gales of wind at Dover generally blow from about west-south-west; but the sea rolls more in from the south, so as to come in from a south-west direction. At present the sea, striking the long face of the western head, rolls up obliquely upon it, and when it comes to the south-east angle, the change of direction is so small that it rolls readily round into the harbour: I may almost say the swell is guided round, by the formation of the head into the harbour. Of course the swell, on striking the pier, is to a certain degree retarded, and therefore the outer part of that swell advancing more rapidly, is brought round so as to roll more directly into the harbour, between the pier-heads. In passing the western pier-head in this way, the swell immediately between the heads is actually *greater* than it is *outside in the open sea*, and no sailing vessel can attempt to get out in what I should call *moderate* weather in a south west heavy swell, and even *steam-vessels dare not undertake it when the weather is at all bad.*"

The evidence of Captain Boxer contains many sound and useful practical remarks; and he is the only one who has given anything approaching to what we consider a *likely* remedy. We select the following passage from his evidence.

"[Ques. 1588.] Would you have the goodness to state to the Committee any observation you have made upon the different works that have been carried on since you have known the harbour of Dover?—I think it was in 1820 they commenced the plan of running sluices through the south head, and cut off a considerable portion of the outer harbour for that purpose; which in my opinion, has almost ruined it as a place of *shelter* for ships in bad weather; but I think it might be improved by running out the south head about 40 feet, so as to cover the north head and the mouth of the harbour from the heavy sea that breaks on it during heavy gales from the south-west, or by covering the mouth of the harbour by a *breakwater* of open piles."

We now come to the consideration of the author's *Plan for the construction of the Breakwater and Apron for the Sluices;* and here we must join issue with him, and point out what appears to us the utter impracticability of his scheme. We shall first give the construction of the breakwater in his own words.

The Breakwater is intended to be carried out 250 feet into the sea, and to be constructed of balk timber, one foot square, of a triangular shape, forming a multiplicity of triangles, each principal or triangle to be tied, or bound together by pieces of timber called whale pieces, four in number; and to be six feet apart, with a ridge purlin, two keels, and two keelsons to strengthen and shorten the bearings of the floor beams. Four tiers of cross tie beams, including those for the floor, are intended to connect the principals or triangles with the whale-pieces, by means of strong bolts, and strapped together at the exposed angles with iron.

The principals or triangular pieces to extend below the flooring or platform, in order to give it stability by penetrating the shingle, the inner ends to be longest where the shingle is deepest.

The inside of the frame work to be planked up with 3 inch plank; about 20 feet at the outer end, and 18 feet at the inner end, and to be caulked water-tight.

The breakwater could be constructed in two or three divisions, and floated out to its proper position, and grounded by filling it with shingle.

The end of the breakwater to be terminated in an oblique direction.

The frame work of the apron to extend to the end of the breakwater, and to be formed by driving piles, either of wood or iron, at proper distances, say 5 feet by 11, and covering them with iron or wood; to be highest at the outer edge, so as to form an inclined plane, both towards the breakwater and towards the sea.

The foregoing description of the construction of the breakwater is intended only experimentally, to show what might be done, and what the effects of the breakwater would be, without the apron, and sluicing power on the west side; as an experiment of the latter could not be tried without its being permanently established, though this would detract one-half from the value of the entire plan. I have given my attention to what might be done experimentally, at a comparatively moderate outlay, because it might be thought hazardous to establish a permanent work without trying what some of its effects might be; and if, afterwards, circumstances should induce the Harbour Board to carry out the other parts of my plan relating to the harbour's mouth, in a permanent work, I consider that the expense of the experiment, would not be thrown away, as the breakwater could be so placed as to form a shield, to protect and afford facilities which could not be obtained without it. On the other hand it may be thought, that there is sufficient evidence to justify a permanent work without first trying an experiment, and more particularly as a very valuable part of the plan could not be tried with the breakwater.

If an attempt were made to construct this breakwater, we very much doubt whether a second division could possibly be fixed before the first was carried away, even in very moderate weather; and we venture to say that if the whole of the experimental breakwater were by chance executed in a favourable season, the whole would be carried away by one of those South-westerly gales described by the witnesses in the evidence quoted by the author. If Lieut. Worthington had but read the description of the failure of the breakwater at Cherbourg, he would never have ventured on recommending his inverted cradle. He might have suggested a much better breakwater for his temporary purpose, by recommending the government to let the Commissioners have a worn-out sloop of war, which might be turned with its keel uppermost, and filled as the author directs, with shingle.

Lieut. Worthington next proceeds to give some *General observations on the principle of the plan*.

Having thus endeavoured to show generally the advantages of my proposed breakwater, I shall now endeavour to point out other important ones which would be derived from my other improvements, as well as the peculiar principle of my plan. But I must first premise, that my observations being intended for the general reader, I have endeavoured to make myself clearly understood, by avoiding the too frequent use of nautical phrases. This explanation I conceive to be necessary, because without it some of my nautical readers might consider that many of my explanations were altogether useless. I think it cannot be denied, that the extension of a breakwater 250 feet beyond the present pier heads, would of necessity shelter the mouth of the harbour—throw off the bay eddy at the extremity of the breakwater, and cause it to unite with the true tide, and thereby assist in carrying the shingle to the north-eastward of the harbour, instead of depositing it, as at present, in front of the north pier head. I ground this opinion on observation . for in no one instance that I am acquainted with, on our coast, does the shingle form a bar either at the extremity or on the east side of any projection into the sea. In proof of this position I beg to refer, as instances, to the Horn of Folkestone, Cheeseman's head, the Castle jetty ; and to those who remember their existence, I might also refer to the large groins which were formerly placed in our bay, of which I myself have a perfect recollection. The bay eddy would likewise be diverted in its course, and would improve the approach to the harbour, inasmuch as there would then be only one tide, or current, to contend with, instead of two as at present, by this eddy running past the mouth of the harbour, as far as Cheeseman's head ; and it is generally acknowledged by all acquainted with the present state of the harbour, that the two tides acting upon the starboard bow and larboard quarter of a vessel, render the approach to it extremely difficult, when it is required to bring her to a small helm and a steady course. My plan would also afford much more space for vessels when working to windward, in-shore, from the northward and eastward ; and allow them to make longer reaches to gain the harbour, because the bay eddy would be thrown off from the end of the breakwater into the true tide, and thereby give greater space for that purpose, when the eastern tide is running in the offing. This would also enable them to shoot or gain the harbour easier, as they would then have the assistance of the bay eddy.

The direction of the breakwater I propose, would be S. S. E. ; so that the end of it would bear about south from the north head ; and the fair way of the channel being about S. E. it would follow that a vessel could sail the harbour either way with two points to spare. This, therefore, shows that my breakwater would be no impediment to vessels getting in or out with such winds as serve them at present.

I would observe also, that the breakwater would be very useful as a turn water in sluicing from the mouth of the harbour; for as the shore naturally falls to the westward, the breakwater would act beneficially in stopping the progress of the water in that direction, and in confining it in a body, in a direct course till it reached the sea. It has been proved likewise by observation, that a breakwater sheltering the mouth of the harbour, would, in a very great degree, lessen the swell inside, as this has frequently been observed to be the result whenever a bank or spit of beach has been formed in the same direction as I propose to place it. * *

It may be urged by some, that by extending my breakwater into the sea, I should only remove the evil so much further out, and that a bar would form, with little variation, as it does at present in front of the north head. Others may contend, that by the action of the tide, the shingle would be carried rapidly past the harbour and clear of the bay altogether; but these opinions are so much at variance with each other, that the truth of either could only be proved by experiment. My own opinion, however, is different from either ; but supposing the effect of the breakwater to partake of both these objections, the result, in my opinion, would be this :—the beach would travel more rapidly past the breakwater, and progress in-shore in a more oblique direction, thereby clearing the mouth of the harbour, as will be shown by the map.

Another great advantage which would result from my breakwater, would be that by its being extended in a S. S. E. direction, the end of it from the north head bearing about south, would break all seas in its wake running from that direction, and to the westward of south. I have also heard it advanced, that it would be no protection to the mouth of the harbour, as the seas usually break at 90 degrees or perpendicular from the wind. In other words, that the seas would break right into the harbour, notwithstanding the protection afforded by the breakwater. This opinion, however, is so contrary to all experience, that I have little fear of its gaining ground amongst nautical men, though engineers and their assistants may endeavour to persuade themselves of its truth. * * The wind blowing from W. S. W. (the most stream wind) would cross the breakwater at right angles ; therefore I presume it would afford shelter during the gales from S. by W. to W. by S. the winds which cause the most sea. With a dead southerly wind there is comparatively little sea ; and with a south-easterly wind, though blowing hard, there is still less. * *

Another advantage that would accrue from the formation of the extreme end of the breakwater, I propose, would be, that it would be next to impossible for a sea to warp or wrap round it ; for in whatever direction it might be struck, the sea would be split, whereas the present formation of the south head, serves as a conductor to the waves directly into the mouth of the harbour. The battering sides of the breakwater, are also adapted to break the seas; for instead of their reflecting, they would have room to expand, and falling through the open work, the feather only of each wave would be seen.

Having extracted some of the principal passages contained in the work, and sufficient we think to give a good general idea of the "Proposed Plan," we will now proceed to state our objections to it. We feel fully convinced from the documents which we have read in the work before us, that the further the pier is extended, so much further will the beach be carried out;—to stop nature's works requires a giant's hand. According to all the evidence given, the beach travels from the West towards the East ; consequently where there are any impediments in its way, there it will collect, gradually shelving down to the foot of the obstruction, as in the case of a solid projecting pier. Thus what was deep water at the time when the pier was constructed, gradually becomes shallow. The beach is brought to the mouth of the harbour by slow degrees and in small quantities, and then washed up by the waves. At the point where the power of the wave is spent, there the beach gathers and forms the bar ; and this is the reason that the shingle does not form a bar at the extremity, where the whole power of the wave is brought into action to carry it away. To illustrate our opinion of the cause of the bar, we cannot do better than refer to the drawings given of Dover Harbour. Here it will be seen how nicely formed is the harbour for bringing the shingle forward to its mouth, where it may be forced by the waves into its throat till it be actually choked. And this will be the case still, notwithstanding any further extension of the pier, if it be not otherwise protected.

We have had no opportunity of surveying the harbour as our author has done ; but from the evidence which he has afforded us, we think we may presume to offer a few suggestions for the prevention of the bar and the improvement of the harbour. Whatever is done, no attempt must be made to prevent the progress of the shingle ;—for that is, in our opinion, impossible. It appears that the prevailing winds in this part of the Channel are from the South South-west, and that whenever it blows hard from this quarter, a very considerable bar is formed in the throat of the harbour. Our object then would be, to break the force of the wind acting in this situation. For this purpose we would advise an *open breakwater*, to be constructed of timber piles, as far out to sea as possible, and quite independent of the present works. This breakwater should be placed at right angles to the Eastern pier, in deep water, so as to allow vessels to pass round at either end, and leave a fair channel open between the breakwater and the mouth of the harbour. This would have the effect of breaking the force of the waves, and preventing their carrying the beach into the harbour ; it would also afford greater facilities for the entrance of vessels. If this were done, and found to answer the purpose intended, an extension of the pier might be made by constructing an open one of timber piles as described by Captain Boxer, where passengers might be landed at all times of the tide. If these works were executed, we have no doubt that the violence of the waves during a gale would be avoided both within and without the mouth of the river ; and that the shingle would travel past the mouth of the river unmolested, and without any danger of being driven into the harbour.

The Eccup Source dissected, and the Fallacies of the present Scheme for Supplying Leeds with Water more fully exposed, in a Rejoinder to Mr. Leather of Leeds. By Henry R. Abraham of London. April 1838.

We shall refrain from passing any observations on the Rejoinder before us, simply confining ourselves to making extracts, as we have done previously in relation to this controversy, in Nos. 8 and 10 of the Journal. We also omit some few remarks of the author, and alter one or two sentences which we consider of rather a personal nature ; and which would be better understood by those who are more immediately concerned in the discussion, than by the generality of our readers unconnected as they are with the town which has been the seat of the controversy.

Mr. Leather's pamphlet is divisible into two parts, one, and by far the greater, that in which he attempts, by an unfounded attack upon myself, to lead your attention away from the merits of his own plan, which alone is the subject of our inquiry—the other, in which he endeavours to support the fallacies of his scheme, by erroneous statements and loose analogies, instead of appealing to facts within his reach, which might, and ought, to have been ascertained by his own experience and observation.

I shall consider both these parts as concisely as possible, and use Mr. Leather as my evidence in both cases.

Part 1st—He begins, by stating that "I profess to prove the insufficiency of that source, which I not long since proposed as abundantly sufficient for the town."

This is entirely false.

My first, as well as every subsequent Report, limited the supply to the *domestic* purposes of 12,333 houses in the upper part of the town ; and I have uniformly stated, that only 650,000 gallons could be depended upon.

My Report not only stated this fact, but pointed out the source from which nearly two million gallons in addition, per diem, ought to be procured, and included also an estimate of the cost of such a supply.

The alleged difference of opinion between Mr. Marshall and myself, related principally to the outlay necessary for the purpose of the supply—that talented and lamented gentleman having expressed an opinion, that no supply could be effected without an expenditure of £250,000.

Mr. Leather again mis-quotes me on this point, and, with characteristic want of candour, conceals that portion of my Report which expressly relates to the necessity of an auxiliary supply. This Report was printed, and any mis-statement connected with it must have been wilful. It is likewise to be found in the Appendix B. And here I must appeal to the Editor of the *Leeds Mercury*, and solicit from him a corroboration of my statements. He knows them to be true; he knows, that so impressed was I with the necessity of increasing the supply, that at my own personal risk of cost, I undertook the survey of a district not included in my instructions, and that he most fairly exerted his influence to protect me from loss.

Mr. Leather next charges me with an error where none occurs; and in the same page actually adopts the very error for his own purposes. He states, at page 5 of his Reply, that I at one time named 230 gallons per minute, as the supply of spring water, and that elsewhere I state a much larger quantity. But I make no such contradictory statement—those differing quantities relate to different circumstances. These are my words in the one case: " At Eccup and Alwoodly, near Leeds, there *are springs of water* whose conflux yields a run of 230 gallons per minute, *independent of any assistance from rain*."

I then state, " That upon examining the account of the weekly gauges of the various springs which unite in Eccup Beck, *the fluctuation* appears to guarantee, at its minimum flow, a quantity equal to 432,000 gallons per diem."

It is obvious that the conflux of the springs in the Beck, is greater than the unvarying quantity gauged at the vomica or source of each spring, because, in the Beck, the rain is included and carried away. In the one instance there is a perpetual supply of pure crystal stream; in the other the polluted mixture of the combined springs with rain water, turbid with mud and soil, and discoloured by metallic and vegetable mixture, *fluctuating*, as I express it, with the fall of rain.

It is the measure of this fluctuation which affords the only indication of the available fall of rain, and yet Mr. Leather has never measured it. I shall recur presently to this important point.

The next occasion Mr. Leather takes to mislead, is, by misrepresenting my statements upon the subject of the evaporating surface of his reservoirs. He would lead you on to infer, that in stating the extent of evaporating surface, I took the area of the Eccup Reservoir only- he says not a word about his Oldman's Reservoir, of 9½ acres, nor of that most abominable project, the one on Woodhouse Moor. * *

I am next represented to have stated, that one-half the fall of rain will enter the reservoir; and Mr. Leather greedily fastens on the assumed admission to lend that support to his case which his own reasonings are incapable of affording. Unfortunately for him, my words are, *that considerably less than one half must be calculated*;—that *I* did not dare to expect that one-half would be obtained. * *

Part 2d—He states, that 31 inches rain, and 5 inches *dew*, form the average annual fall—that one half of this, or 18 inches in depth, is not only necessary for the town, but also, by a lucky coincidence, the precise quantity which will be caught in a reservoir. The remaining 18 inches is therefore required for natural purposes. But as he states 31 inches to be an average, then, necessarily, there are years in which the quantity of rain is much less than 31 inches; and indeed, we know there are instances of such falls as 18 inches only. On such occasions Leeds is to have *no water*—for nature will be served first. We know that falls of 20, 22, 24, and 26 inches per annum are common cases. In all such years, Leeds, by Mr. Leather's showing, will have no water; for, when the weather is thus dry, the evaporation increases beyond the mean of wet years, and Mr. Leather cannot keep a supply in store, because his quantity is shown to be no more than 1,333,800 per diem, and the town requires at starting 1,200,000. We will, however, suppose the alleged daily surplus of 133,800 reserved for a whole year, there is not then 120 days' supply of water, dregs and all, instead of 365 days' supply; so that, according to Mr. Leather's own statement, in all hot years, when the average of rain is lowest, and when water is most required, you will have no supply; and should two consecutive years of drought occur, the result would be dreadful, because six previous wet years could not provide a store of water sufficient for the demand.

Taking Mr. L.'s statement - that 18 inches of water, including dew, yields 1,333,800 gallons per diem, he will give the town 1,200,000 gallons per day, the rest, or 133,800 gallons per diem, he will keep in his reservoir, deduct his own quantity of evaporation, 4,260,168 gallons per annum, to make the whole calculation his own, and you will find that to fill his Eccup reservoir alone will take *five and a half years*, while to fill all of the three reservoirs it will take nearly six and a half years.† * *

Mr. Leather considers it *probable*, that the town, which in ten years time will require, according to his computation, 1,800,000 gallons per diem (but according to mine, and allowing only one-half the London supply, 8½ million gallons), may be supplied from the same source, which he now, from an 18 inch fall, calculates will only supply 1,333,800, if his most sanguine hopes are fulfilled. Will Mr. Leather perform this miracle of increasing the supply to meet the demand?—should he do so, he will have no water for his huge reservoirs, he will then have but a bare daily supply of thick-coloured water.

Yet again, in opposition to his own theory, Mr. Leather states, at page 10 of his Reply, that evaporation and absorption cause a loss of ten inches per annum (no matter what the soil, temperature, or locality), and that the excess of downfall above this quantity will be returned by the springs and living streams—so that 26 inches are returned, including *dew*. * * Does Mr. L. suppose that the living springs, in a particular district, owe their birth to the downfall of rain upon that district? There are hundreds of square miles in our country which receive as much rain, and more dew, than Alwoodly and Eccup, and yet neither springs nor living streams bless the district; but the soil is the collector for some more favoured, and in many cases, very distant tract of country. The springs of Eccup and Alwoodly, may be no more influenced by the rain which falls upon the district of drainage, than the fountain which plays in the Temple is by the rain which drops in Fleet street. * *

In the eighth Bridgewater Treatise, page 311, it will be found that instead of 26 inches of rain being returned to streams and springs, *only* 4 inches per annum flows to them. This is as stated by Dr. Thompson. It is obvious, if Dr. Thompson be right, your expenditure of £100,000 may redound to the benefit of Mr. Leather and some other persons.

We will, however, set the knowledge and authority of Dr. Thompson, as below the information and experience of Mr. Leather; and, *doubling* Dr. Thompson's quantity, will allow 8 inches, even then it is plain that Mr. Leather calculating that 26 inches is necessary, does not procure one-third the required quantity. * *

The whole fact is this. There are some springs which run the same quantity winter and summer, rain or dry—there is a brook, and only one little brook, which carries off all the rain which falls upon the district. The springs flow into this brook, and unite with the drainage. In fair weather, this brook is beautifully clear; in rainy weather, it is very muddy.

All agree that the springs alone run about 230 gallons a minute; and after a drought, that is about the measured quantity flowing through the brook. When the rain increases, the run of water in the brook is increased according to the violence of the fall, rather than in an exact proportion to the quantity of rain. A storm will suddenly charge the brook, while six times the quantity falling mildly, will have little effect; the ground, in the first case, is charged more suddenly than its porosity can carry away; while, in the other, saturation slowly occurs on the surface, next absorption through deeper soils, together with evaporation, slow or rapid as the case may be according to the condition of the atmosphere.

What then have we to do before we can justify the expenditure of £100,000? Put up a little trumpery pluviometer in Leeds, which may be disordered by a hundred accidental circumstances, and dispense with actual local observation and experiment? No! gauge the stream—see for one year how much water it produces, and form your calculations on the result. * *

Which is better, the result of three years' practical experiment and local observation, or an assumed conclusion of a downfall of rain from calculations made at distant places? * *

Read what Mr. Anderson states to be the available supply from the tract: " 436,000 gallons per diem, can, I have no doubt, be furnished."

Mr. Leather declares, 1,800,000 to be the quantity.

With, perhaps, less caution than Mr. Anderson, I stated, that a maximum of 650,000 gallons might be depended upon. Mr. Mylne, Mr. Jardine, and actual experiment have justified my report. On the other hand, here is your engineer, resident on the spot, who does not give you the results of any observations to prove the actual fall of rain which is the average of your district; but, supplying you with scraps of quotations from books, to prove the *average fall throughout England*, expects you to accept these loose computations, instead of that which he dares not give you; and yet this engineer alleges he has been employed nearly eighteen months in taking daily gaugings of the water. * *

In alluding to my remarks about the *dew*, utterly ashamed of having included it in his estimate, he says he never calculated upon the dew running into the reservoir. Hear his evidence and judge: " The fall of rain is 31 inches, and the dew 5 inches, *which gives* 36, *one half of which gives* 1,333,874 gallons per day." But the fall of rain may not be 31 inches for your district; for at Brandsby, near Leeds, 200 feet higher than York, in 1833, it was only 24 inches, and how much less in other years I know not. He states Wharfdale to be proverbially wet. A main tract of drainage generally is so, and to the disadvantage of converging tracts. Thus, in Alwoodly valley, the rain is most transient and sudden; the clouds are seen rapidly converging to their grand line of cumulation. The atmospheric changes and currents of air are violent and instantaneous; and, while on the northern aspect of the vale, the rain may be suddenly pouring, the southern may be, and is frequently, all sunshine. * *

One word as to the projected reservoir on Woodhouse Moor. Why are the best houses in Leeds, in the high district, to be deprived of a supply above the level of their kitchen-sinks, and to have water closets denied them? * *

The inhabitants of Leeds were stated by Mr. L.'s counsel to be about 150,000 in number. Mr. Leather makes it necessary that one-third of this population shall or must go without water. That third will be those who most require it—the Poor. He next states, that the remainder shall be supplied with water at the rate of 1,200,000 gallons per day.

CUBIC FEET.

† Eccup Reservoir	39¼	million, or about 246 million gallons
Oldman's	3¾	
Woodhouse (?)..	½	
	43½,	or about 271 million gallons.

This is not one-sixth the quantity allowed for a well supplied London district; and just *one-half* what the very worst supplied London district now has; yet one-third of your inhabitants are to seek even this little blessing in vain.

In ten years after the works are finished, when Leeds ought to have the benefit of water universally diffused, 210,000 persons, according to Mr. L., will require water. Of this number, if Mr. Leather's calculation of an 18-inch supply prove correct, one-half only will have water; if his high probability turn up well, two-thirds will be supplied: but, in both cases, with only one-half the quantity given to the worst supplied London district. Now, such is to be the supply, even if Mr. Leather succeed in obtaining all the water he chooses to anticipate. * *

I will now show you that even the promised supply, inadequate as it is, will never be afforded. There is not the water for you.

	ns per diem.
The springs of Eccup yield, per diem, not more than -	333,000
Accurate gaugings of the Eccup Beck, during three years, show that the 1,200 acres of drainage will supply, in its natural percolation, about - -	200,000
But it is presumed, that by care, a larger supply may be obtained; and that although the Beck only indicates 200,000, we may add, for escapes, &c.	

Now this is the practical working of the problem; and if you get as much water as this you will be fortunate. The vessel in which this is measured stands before you. Go to Eccup, and judge for yourselves—ordinary observation will detect the fallacy. * *

The pure spring water should be delivered to you fresh from the springs on alternate days, as I proposed; you would then always have delicious water to drink and cook with. - Mr. Leather mixes it with drainage water.

On the other days, your rain-water supply should be served, and after standing a certain time to deposit the dirt from the lands, this would be received into a separate tank or cistern, for household purposes. Read what Mr. Leather does with this delightful spring water. He pours it into a reservoir with an earthy clay bottom, which never can be properly cleaned out, and mixes it with the rain as it falls, and without any provision for filtering that which he pollutes, sends it diurnally, thick and muddy, to Leeds. No water which flows over fallow, or loose soiled cultivated districts, is fit to drink until about thirty, or more days (according to the weather), after the fall.

A Practical Treatise on Rail-roads, and Interior Communication in general: containing numerous Experiments on the Powers of the improved Locomotive Engines; and Tables of the comparative Cost of Conveyance on Canals, Railways, and Turnpike roads. Third Edition, with additions. By NICHOLAS WOOD, Colliery Viewer, Member of the Institute of Civil Engineers, &c. London: Longman and Co.; 1838.

This is the only treatise with which we are acquainted that enters fully into the history, theory, and practice of Railways; and its utility appears to be very extensively admitted, and very firmly established. A work of this nature, treating of a subject of great and growing interest,—a subject likewise on which observation and experience are daily accumulating new facts,—seems necessarily doomed to one of two fates. If in its original form it be really worth little or nothing in itself, it will die a natural death in its first edition, notwithstanding the interest of its subject. But if to begin with, it be in any degree worthy of its subject, successive editions will give its author successive opportunities of amending, enlarging, and renewing his work that it may constantly keep pace with the march of improvement in the art or science of which it treats. By appearing now in a third edition, Mr. Wood's book proves itself to belong to the latter class; and it has partaken largely of the additions and improvements of which we have said that works of that class are susceptible. We remember it in its youth, slim and slender like a growing lad; then again,—we suppose we must say on attaining its majority,—with its figure well filled out, and its form that of a full-grown book; and now its proportions grow most Justice-like, and we find it as it should be,

"Full of wise saws, and *modern* instances;"

the author will take care, we doubt not, that we shall never have cause to pursue the quotation further and lament over the

"—— big, manly voice,
Turning again toward childish treble.—"

Mr. Wood, as he states in his introduction, has in the present edition availed himself of the valuable information given by M. Pambour in his work on Locomotive engines. He has further had recourse to Professor Barlow's experiments and calculations on the strength of rails, for information on this important subject. And the practical experience of seven years of regular and constant traffic on the Liverpool and Manchester line, has enabled him likewise to enrich the new edition with various interesting and important particulars respecting railway conveyance, both in itself considered, and as compared with other modes of locomotion. We shall endeavour to give a general notion of the contents of the book, making a few observations and extracts as we proceed.

The first chapter briefly describes the nature of *Internal Communication* in general. To begin from the very beginning, we have one short section on pack-horses, and another on military and turnpike roads;—which are all very well, for the time seems to be coming when these things shall be of the things that were, and a knowledge of them be preserved in books for the information of the pains-taking Dryasdusts of a future generation. In the third section, the author endeavours to trace the origin of railways in Great Britain; and under this head we find some curious and interesting matter. Mr. Wood considers that they were first introduced at Newcastle-upon-Tyne, between the years 1602 and 1649, probably a considerable time prior to the latter period. These earliest railways were of timber, with longitudinal sleepers and cross ties; somewhat similar to the construction which some of our modern railways are adopting, with the addition of wrought iron rails. The next improvement is stated by our author, to have been the substitution of cast iron rails for wooden ones, which appears to have taken place between 1738 and 1768, the latter being however the more probable date. Malleable iron rails, we are informed, were first tried about the year 1805; but their use was very limited until 1820, when

Mr. John Birkinshaw, of the Bedlington iron-works, obtained a patent for an improvement of their form. Previously to this, their section was rectangular; and either the narrowness of their surface produced great injury to the wheels, or, by increasing the breadth, the sectional area was increased, and consequently their cost became so great, as to exceed that of cast iron, and thus cause the latter to be preferred. Mr. Birkinshaw produced a rail, which combined the same bearing surface as the cast iron rails, with that form which likewise exhibited the greatest strength, and thus obviated the objections to the use of those rails. Varius modifications of Mr. Birkinshaw's form of rail have since been adopted, but this principle of manufacture now forms the description of rails most generally used. Their safety, in rapid rates of travelling, renders the use of them almost indispensable; and they have, on that account, entirely superseded the use of cast-iron, on all public railroads.

The fourth and last section of chapter I., traces in like manner the history of Canals.

The attempt to form the Sandy Brook into a navigable canal, from the river Mersey to St. Helens, in Lancashire, in 1755, appears to have been the first of the kind in England; and since that period, they have been extended into almost every quarter of the island. Such was the rapidity of their extension in England, that, between the years 1760 and 1803, no less than 2292 miles of canal were opened. * *

At the time of the publication of the first and second editions of this Work, scarcely any experiments had been made on a large scale, to elucidate the capabilties of canal navigation,—none, certainly, satisfactory; since then, the competition of railways has aroused the dormant spirit of the canal proprietors, and various experiments have been made, to ascertain the amount of resistance of boats dragged at different velocities; attempts have been likewise made, to adapt the power of steam to propel the boats upon them, and other expedients have been adopted, to increase their activity, as a mode of traffic, and especially for the conveyance of passengers. So far as we are able, and with the information which a restricted inquiry has enabled us to acquire, upon the subject of so important a question; it will be our duty, to place those modes in competition with each other, before the public fairly and impartially.

The second chapter is entitled, *Description of Rails and progress of Railroads.* It describes the various forms of rail that have been in use in England from the first introduction of railways to the present time. It institutes likewise, a comparison between the advantages of cast and wrought iron, and between the properties of edge and plate rails.

Chapter III. is *On the Strength and Stiffness, and best Form of Section of cast and malleable iron rails.* The author gives various statements to show the annual wear of wrought iron rails, from which he draws the following conclusion.

We may, therefore, take the wear of the rails to be about one-tenth of a pound per yard per annum, which, supposing the whole to result from the wear, on the upper surface, will be one eighty-fourth part of an inch; if the top, or wearing part, of the rail were therefore an inch in depth, the rail would wear eighty-four years. The whole of the wear, above alluded to, does not however take place upon the top; a part, though probably a very small portion is attributable to exfoliation, by the action of the air: supposing, however, that the wear, by the action of the wheels, amount to one-tenth of a pound per yard per annum; if the top, or bearing part of the rail, be made an inch in depth, it will be sufficient for all the purposes required. Any increased depth and weight, which would not be required for above eighty years, would, at compound interest, at the end of that period amount to a greater sum than

it would be expedient to expend for such a purpose, considering the remote period at which it becomes useful.

This chapter contains thirty-five tables, exhibiting the results of numerous experiments on the strength and rigidity of rails of various shapes and qualities of iron.

The fourth chapter will be found particularly valuable by the engineering student. It treats very fully of *the Formation and Construction of Railways** from the first setting out of the line, to the laying down of the rails; with practical directions for the widths of the roadway, the depths of the metalling to be laid on the surface, the proportions of the slopes of the cuttings and embankments, the method of drainage, &c. We fully concur with Mr. Wood in his remarks under the head of "width between the rails," respecting the want of judgment shown by the legislature in abandoning the standing order for regulating the construction of railways in this important particular.

It is impossible to conceive the confusion which may be the result of this departure of the legislature from a standard width for all railways; especially if railway companies and engineers follow the dictates of their own opinion, without reference to the general convenience of the public. The delay, expense, and inconvenience of changing from a line of railway of one width to another of a different width, where despatch and rapidity of travelling is the great characteristic of the system, must be inconceivable. It is due to the public, that a full and comprehensive inquiry should be instituted by the legislature, to determine the proper width now to be adopted; not only with reference to all railways to be made in future, but likewise with reference to those already made; and when a conclusion is come to, and the best width, under all the circumstances, determined upon, it should be made a standard in all railway bills, and should not be allowed to be departed from, under any pretence whatever.

Without presuming to determine upon so important a question, on which there is a great difference of opinion amongst engineers, we shall for the present assume the width between the rails to be four feet eight inches and a half. The breadth of the bearing part of the rails cannot vary much; about two inches and a half seems to be the width agreed upon by almost, if not all, the engineers of the different lines of railway in England. The width between the outside of the rails will therefore be five feet one inch and a half; or five feet one inch, if the breadth of the rail itself be two inches and a quarter.

The following description of the mode adopted by Mr. Stephenson for carrying the railway over Chat Moss on the Liverpool and Manchester line, will be found interesting, as showing how easily this at first sight insurmountable difficulty was overcome. We remember to have heard it stated in Lancashire, that the line over Chat Moss was proposed by the powerful opposition which beat the Company from the line first designed, nearer to the old turnpike road; they thought thus to *swamp* the railway altogether,—but in those days it had not been seen what a Stephenson could do towards surmounting apparent impossibilities.

The modes of passing yielding ground, mosses, or bogs, adopted by some engineers, may however be described in this place, and the Chat Moss, on the Liverpool and Manchester railway, being the most extensive moss yet passed over, we shall give the plan adopted by Mr. Stephenson, for carrying the railway over this moss.

This moss is of considerable extent, comprehending an area of about twelve square miles, being of so soft and spongy a nature that cattle cannot walk upon it, and an iron rod sinks with its own weight. The depth varies from ten to thirty five feet, resting on clay and sand. The distance which the railway was to be carried over it, was upwards of four miles and a half, an undertaking which required some degree of nerve to contemplate. It is necessary to premise, that in carrying the railway across the moss, the level required that it should in some places be twelve feet above, in others nine feet below, and to vary from these to level with the original surface of the moss. We have, therefore, three distinct operations, viz., *embanking* the railway above; *forming a cut below*; and forming the road *level with* the moss.

ng the Railway above the Moss. There is another moss, of considerably less extent than this, over which the railway passed, and which, at one end, was terminated by an extensive cutting of clay and gravel. As an embankment of four feet in height had to be formed over this moss, the materials from the excavation were used for this purpose. The moss was about twenty feet deep, and it was soon found, that as the materials were successively laid upon the moss the whole mass gradually sunk; and when the embankment was finished, although the actual level of the railway was only four or five feet above the original surface of the moss, the quantity of the metal deposited would have formed, on ordinary ground, an embankment twenty-four or twenty-five feet high; with such materials, therefore (clay and gravel), it would have been impossible to form an embankment over Chat Moss. The quantity required, and the consequent expense, would have been enormous. Mr. Stephenson had recourse, therefore, to the moss itself, for materials to form the embankment, which, by its inferior specific gravity, would not sink to such an extent as gravel and clay. In its natural state, the moss was unfit for this purpose; but drains were cut, five yards apart, which laid the moss between the drains dry, and rendered it excellent material for the purpose. With this material, embankments were formed upon part of the moss, and it was found to require only about four times the quantity of material that would have sufficed for sound ground, and the road appears in quite as good order as in any other part of the line.

Forming a cut below the level surface of the Moss, was accomplished entirely by draining; the drain was cut along the line of the railway, eighteen inches to two feet deep, which laid dry that portion of the moss between them. About twelve inches in thickness thus dried, was excavated at a time; and it was in that manner successively drained and excavated, until the proper depth was obtained. The permanent road was then formed in the manner hereafter described.

Laying down the road upon the surface of the Moss. Drains were first of all cut on each side of the line, and lateral ones, where necessary, to carry off the water. By this means, a certain depth of moss on the top was partially consolidated, and formed a layer or surface of dry moss, of considerable tenacity; upon this, hurdles nine feet long and four feet broad, wickered with heath, were laid down transversely. In many places, only one layer of hurdles was required; but when the moss was very soft, two layers were used. Upon this was laid about two feet of ballast, or gravel, to form the permanent road; and wooden sleepers, stretching across each line of road, were used to lay the rails upon. The stability of the road, therefore, depends solely upon the tenacity of the materials, supported by the buoyancy of the moss. When we consider, however, the area of the base thus firmly united and bound together, and the support which even so spongy a substance as the moss must give to so extensive a platform; it is natural to suppose that the impression made upon so great an area, by the pressure of so inconsiderable a proportion of the whole weight as that of a train of carriages, must be slight indeed; and we find, that since the opening of the railway, the passage of the traffic over the moss proves that the road is exceedingly stable. It may be necessary to remark, that the surface of the moss is higher than that of the country bordering its edge.

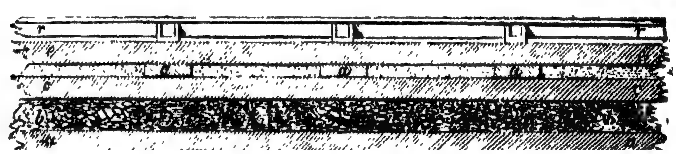


Fig 2.

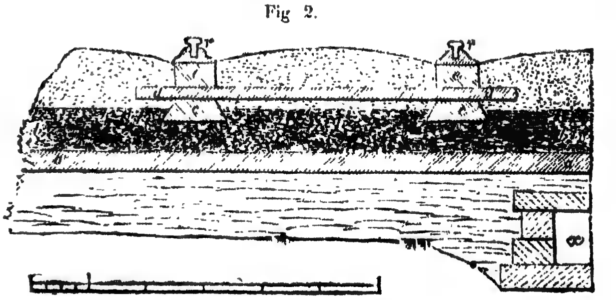

Scale of Feet.

Fig. 1 is a longitudinal, and fig. 2 a transverse section, showing this mode of forming a railway over a moss; *a a* are the hurdles, or wickered foundation, which may either be single, or two or three layers, according to the tenacity of the moss; *b b* is the coating of sand or gravel, resting upon the wicker work, small branches of trees, brushwood, or furze, being laid down upon the hurdles; upon this gravel, either longitudinal sleepers, *c c*, are laid down, with transverse sleepers, *d d d*, laid upon them, or transverse sleepers, without the longitudinal ones, according as the moss may require.

The longitudinal sills, *c c*, are then laid along the transverse sleepers, upon which the chairs and rails are laid down in the usual way. A moss has been passed, in the manner shown in the above figures, upon the Garnkirk railway, near Glasgow, by Messrs. Grainger and Miller.

The subject of chapter V. is the *Construction of Carriages adapted to railroads*, in which will be found a description of various recent improvements in the construction both of goods-waggons, and of passengers' carriages.

We are obliged to defer any further notice of this work till next month, when we shall resume our review of it. Meanwhile, we confidently recommend it to the continued favour of the profession, and especially to the notice of the engineering student;—his library indeed cannot be said to be complete without it.

appears inconvenient and disagreeable. *Railway* seems now we think the more usual term; though we perceive the late parliamentary report adheres, as legal documents usually do, to the older word, which in this instance is *railroad*.

The Book of the Grand Junction Railway, forming a Guide from Birmingham to Liverpool and Manchester. By THOMAS ROSCOE ESQ. assisted by the Resident Engineers of the line. Illustrated by steel plates. Part I: London; Orr and Co.

This work, as stated in the prospectus, will be completed in about six parts, each part containing three engravings. The plates in the number at present before us, are neatly engraved, comprising some interesting portions of the railway and the line of country through which it passes. We are however disappointed with the letter press, which is very meagre, and deficient in new matter. One half of it is occupied by an introduction very little to the purpose; and when we come to the first chapter, we find it mainly consisting of an account of the engines which were entered for trial for the prize offered by the Liverpool and Manchester Railway Company previous to the opening of their line,—a subject which has been treated in print over and over again. We should have expected that the author, assisted by the resident engineers of the line, might have found more important matter to fill the scanty space allotted for the letter-press in this his first number. The materials, we are convinced, are ample; and we hope that the next part will offer a more favourable sample of the work, than the present.

LITERARY NOTICES.

A new edition of *Sir Henry Parnell's work on Roads*, is just published. It appears to have received considerable additions; but having been unable to find either time or space in our columns allotted to Reviews, to give it the attention which it claims, we have thought it better to defer the consideration of it to our next number.

Mr. Weale has brought out *a New Theory of the Steam Engine by the Chevalier G. de Pambour.* This treatise seems to embody the valuable papers on the subject by the same eminent author, which appeared in Weale's Scientific Advertiser. We are glad to see them in this more permanent form; and we shall notice the work more at large on a future occasion.

The Railway Company's, Engineer's, Contractor's, General Builder's and Manufacturer's Labour wages tables, by E. Perkins. London: Effingham Wilson. A ready reckoner for wages, printed in a remarkably bold, posting-bill kind of type. For our own part, we should prefer a smaller type and a smaller book; but there may be others to whose failing eye-sight this feature of the work may recommend it.

ORIGINAL PAPERS, COMMUNICATIONS, &c.

RALPH REDIVIVUS—No. 8.

THE RAILWAY ENTRANCE, EUSTON SQUARE.

Just as this article was about to be put into the hands of the compositor, a letter, signed "Omega," was placed in my own, which I will therefore take the opportunity of here noticing. The writer expresses himself so obscurely that it is quite impossible to make out the meaning of some of his paragraphs; but the purport of the whole is plain enough. He is exceedingly wroth with Ralph Redivivus, and perhaps not without sufficient cause, since it is very possible that he may be some party more than ordinarily interested in what I have said; and may, therefore, have despatched an anonymous letter to the editor, hoping that I shall be roughly taken to task by him for injuring the character of his "valuable journal," in the estimation of such persons as "Omega." I say anonymous letter, because it is altogether differently circumstanced from an article intended for insertion in the Journal, with a fictitious signature attached to it. Any one, except "Omega" himself, must at once see this; and that it would be utterly impossible to conduct any periodical whatever, were an editor to attempt to steer his course according as he may be directed by any or as many individuals as may—for some purpose of their own—think fit to set him right.

His letter is a direct attack upon a series of articles that, while it continues, constitutes a feature in this publication. Nevertheless, he thinks he has only to express his decided disapprobation of "such like things," as he elegantly phrases it, and the Editor will out of complaisance to one who conceals himself behind a mask, immediately alter his arrangements, and forthwith suppress what does not happen to be to the taste of an individual.

That my lucubrations would please every one, I never imagined: for I am perfectly aware that they contain many opinions, both general and particular, that must be positively offensive to many, and prove so in proportion as they are felt to be advanced with ability, and to contain some sound stuff in them. Feeble, nerveless, and unmeaning, must that criticism be, which endeavours to propitiate all by displeasing none; and I am tempted to entertain a better opinion of my papers, and even feel increased confidence in myself, when I find that I have made such a person as "Omega" shows himself to be, squeak out piteously against me. "All R. R's. papers," he says, "are *trash*;" which it must be owned is a conveniently summary way of deciding the matter; as it saves all trouble of attempting to bring forward any specific charges. I do not in the slightest degree question his sincerity; yet I may be allowed to hint that it is strange that such being the case he should have forborne so long, instead of cautioning the editor against such trash, immediately after the first specimen. Or how happened it that if he entertained so very mean an opinion of the first two or three papers, he should have continued regularly to peruse them, to the waste of his precious time, and the ruffling of his temper? After this I may be forgiven for imagining that there must be something or other so unusually attractive in them, that "Omega" was fascinated to read them in spite of himself. In calling them *trash*, therefore, he libels his own taste; because, did he consider them to be such, he had ceased before now to bestow any notice on them.

All this leads me strongly to suspect that there must have been something in my last paper that especially annoyed him, and caused him to resolve manfully to make his complaint to the editor at once; still he might as well, while he was doing so, have said where the shoe pinched him. Yet instead of speaking out intelligibly, he has strung together a set of vague paragraphs, so disconnected and indefinite, that it is impossible to perceive their drift. In one of them he says—"It should be explained, why to examine critically the Post Office, it is necessary 'to cross over or go round from Goldsmith's Hall!'" I am sure nothing further than this is necessary to explain what a blunderer "Omega" must be. Who ever said or thought, that in order to examine critically the Post Office, it is *necessary* to go round from the other building. Certainly not Ralph Redivivus. But there are some matter-of-fact individuals, who cannot comprehend any thing, if it be not expressed in the most ordinary way. To every one else it must be evident enough why I spoke of going round from Goldsmith's Hall to the Post Office; namely, because the first mentioned building had formed the subject of my preceding paper.

Perhaps I have bestowed far more notice upon this matter than either it deserves in itself, or than is altogether becoming on my part. It gives me however the opportunity of saying once for all, in the editor's name as well as my own, that those who do not relish these papers, must pass them over:—and in every periodical there will inevitably be something that is not equally to the taste of all readers. Should any one, however, think fit openly to controvert some particular remark or point of criticism in these papers; I make no doubt but that the editor will allow him to state his arguments as fully as he pleases; and as for myself, I can promise that I shall not be found backward in taking the field against such an adversary.—Come on, Macduff!

Leaving to others the liberty of attacking and combating my opinions, I assume to myself the right of promulgating them. Accordingly, in my last paper I spoke out very plainly against that system of servile, pedantic imitation, which prevails in regard to copying Grecian columns and entablatures with hair-breadth exactness,—which would proscribe all invention as innovation, and all innovation as downright enormity. What then am I going to say of a structure which aims at giving nothing more than a Doric propylæum? To abuse it heartily? To rail at it in good set terms? So far from it, that I readily admit I admire it as being a very noble architectural object. In so doing, I must further admit that I am grossly inconsistent. Not at all: the thing itself makes no pretensions to originality of design, but shows itself most undisguisedly to be borrowed from the antique. This is not a case where while particular parts are scrupulously copied from the antique, the expression of the ensemble is altogether foreign to it. On the contrary, the imitation here observable, is legitimate, and no more partakes of plagiarism than does a translation of Homer or a cast of the Laocoon. With the precise forms and arrangements of Grecian architecture, we have here its spirit likewise; and that also to the exclusion of anything interfering with it. Nor that alone; but we here behold the full majesty and severity of the order exhibited upon a scale that renders it truly imposing. Till now, we had nothing that could convey an adequate impression of the majesty of a Doric portico; for if not diminutive in themselves, most things of the kind have been made to appear so in comparison with the masses to which they are attached; and failing to satisfy the eye by grandeur, they look, for the most part, affectedly harsh and cold, particularly when compared with other parts of the same design.

In this entrance, on the contrary, we are made sensible of the full

effect of the order, without there being anything to disturb our satisfaction. We have the effect not only of magnitude, as well as of forms, but that also arising from breadth of light and shade, heightened by that of great depth, and the contrast of perspective; so that, although each front consists merely of a distyle in antis, yet as the columns belonging to the hinder one are seen beyond those in front, and opposed to them in colour, accordingly as the sun happens to strike either upon the former or the latter, very great richness and picturesque vigour are combined with great simplicity. Not only do the further columns serve to fill up to the eye the intervals between the nearer ones, from being shown within the same space, where there would otherwise be only two; but their position seems to change according as the spectator shifts his station from one side to another,—advances to or retires from the front. Wherever there are striking effects of this kind—which may be understood to exist, from what is shown in drawings and views, yet cannot be represented by them—architecture seems to acquire motion and life, nor are they the less valuable because they cannot, like decoration, be introduced ad libitum, but depend upon circumstances that very rarely favour them. All the more desirable is it therefore that whenever an opportunity does present itself it should be made the most of; that is, made as much of as the subject itself will allow. Instead of which, so far from catching at such opportunities, architects appear to shun them, and to study nothing so much as to avoid the species of originality that might be derived from perspective combinations. Of this we have striking proof in the Post Office; where notwithstanding that the plan most forcibly suggested that the portico and hall should conjointly be made to form an uninterrupted vista through the centre of the building, which might have been accomplished without further variation of the actual plan than the slight one of substituting two columns in lieu of the large door, between the antæ on the wall which now entirely divides the hall from the portico,—the architect preferred adhering to what in general cases is done out of sheer necessity. There was an opportunity which a man of original talent,—I might say a man of classical taste,—would on no account have let escape him. And how captivating a picture such an extensive open atrium would have formed, where the lines of the inner columns would have exhibited themselves so piquantly behind that of the external colonnade, must be obvious, I should conceive, to even the dullest imagination. Nevertheless, it would perhaps be expecting too much, to expect that on any one occasion Sir R. Smirke should deviate from the settled track; for his designs partake one and all of what the Germans term Schlendrian.

Although in itself a digression, yet as what I have just been saying serves not only to supply a remark omitted in my last paper, but also to illustrate my present subject, I will not pretend to apologise for it. In fact the apologies employed on such occasions, are mere unmeaning forms, childish make believe; for if they be sincere, the writer confesses himself to be an ass, begging pardon for the impertinence he might cancel by drawing his pen through it.

Of porticos we have examples enow already; since each additional one does little more than increase the number, without exhibiting any marked peculiarity of design, difference of character, or difference of scale. The more readily therefore do we welcome this Doric propylæum, which for the scale upon which the order is executed so greatly exceeds every other specimen of Grecian architecture in this country, as to be on that account alone conspicuously distinguished. Except St. Paul's, where the magnitude of the entire fabric greatly takes off from the apparent size of the columns, we have scarcely any in the metropolis which exceed thirty feet, a height in comparison with which that of those in some of the public buildings abroad, becomes gigantic. Even those of this railway entrance, although forty-eight feet high, would appear more remarkable for bulk than loftiness, beside those of La Madeleine, at Paris; and the whole propylæum would look very moderate in size, if it could be viewed together with such a colossal mass as the Arc de l'Etoile. Measured however by the standard of our English buildings, it becomes in its turn colossal, and has the air of being not only a public, but a national monument; and is many degrees superior in taste as well as in imposing grandeur of scale to the celebrated Berlin Propylæum called the Brandenburg Gate. In general design it bears a close resemblance to the Porta Ticinense, or di Marengo at Milan*, erected by Cagnola; which also consists of two fronts, distyle in antis (of the Ionic order) connected by lateral or end walls. Yet there those last-mentioned parts are pierced with a lofty arch, which openings, besides seeming quite uncalled for as entrances, detract from the expression of solidity; whereas our railway edifice is indebted for much of the nobleness of its character to the depth of surface it presents on its sides, both as seen through the columns and beheld externally. In fact, a good deal of its beauty is lost in a direct view, were it only because such view excludes some of the most striking embellishment,—indeed, I might say all of actual decoration introduced into the architecture,—namely the series of large heads in the cymatium of the cornice on the sides of the building, and the range of antefixæ above it; which together give a richness and finish to this specimen of Grecian Doric, very superior to that of any other imitation of it we possess. Therefore, although very well executed and otherwise conveying a very correct idea of the design, the lithographic view of this Railway Entrance, being little more than a perspective elevation, by no means does justice to its actual appearance; but on the contrary, keeps quite out of sight the most remarkable particulars of detail. Yet it is precisely to beauties of this kind that public attention requires to be directed; for they it is which give fidelity and spirit to what, but for them, is but an imperfect and maimed copy of the professed original. If we must be imitators, the least we can do is to take care that we do not omit those graces which constitute the finishing touches of architecture; as ornaments indeed superfluous to the building, but at the same time so indispensable to the design that unless they are introduced, some equivalent ought to be substituted for them; or if that cannot be done, the whole ought to be so recast as to disclaim imitation altogether. As the building is not quite finished, and as I have also left many particulars unnoticed, I may, perhaps, return to the subject in some future paper. Yet promises being—as every one knows—confoundedly brittle things, I make no positive one to that effect. In the meanwhile I leave my readers to chew the cud of the following piece of genuine Carlyle-ism: "all criticism that does not go forth from a creative re-conception and re-organisation of the thing criticised (to which a principle of sympathetic vitality in the critic belongs) is worse than nothing, or vanity. It is an ill-natured, or at least an idle bird, pecking at berries which it cannot eat."

THE PARKS AND METROPOLITAN IMPROVEMENTS.

"I never knew any good accrue from doing more than one thing at a time," was the emphatic observation of a learned and noble lord a short time since; and with the axiom, from so great an authority, yet ringing in our ears, we are desirous of continuing and bringing to a conclusion, and we hope, of exhausting the subject of our *national monuments*.

We think we have with us the general opinion, that bronze is in reality the least durable of materials for such purposes, and that a statue easily overthown or easily converted to other forms and uses, is equally inappropriate. We have not assumed a fact and then argued upon it; we have brought forward our authorities, the experience of all times, of the plunder of all ages and under every variety of circumstances, and from that experience we have deduced our conclusions.

"Exegi monumentum ære perennius"

was the boast of Horace, whose prophetic vision taught him the fleeting nature of the immortality bestowed by the statues that were starting up at every corner of the streets of Rome, to the memory of statesmen and conquerors. How truly the prophecy has been verified this inquiry has fully shown.

But it will ever be the desire of man to place upon record the gratitude he feels to his benefactor by some visible object, and to relieve himself from the load that oppresses him by exhibiting some public testimonial; and although the moment of enthusiasm is scarcely the time for a careful investigation of the most proper mode of performing this duty, it is nevertheless not the less necessary; and we are therefore inclined to enter more fully into the subject in the hope of fixing some certain data upon which we may in future proceed.

To attain this object, we must pass before us the descriptions we have of monuments that have been erected to perpetuate the fame of heroes, kings, or statesmen. Of these, the most ancient are the obelisks of Egypt; and thence gradually approaching our own time, the monuments of Greece; the triumphal columns and arches, and the

* Speaking of this edifice the author of "Notes Abroad," (a work abounding in clever and original architectural remarks) says—"Although there is a degree of Grecian simplicity and gracefulness in this structure, very unusual in Italy, there is also the decided impress of the Italian school: the capitals are meagre compared with those of the Grecian Ionic, and their want of bulk and depth occasions the columns themselves to look disproportionably tall, and tall they would be were their shafts reduced by deep capitals and neckings. Again, the capitals of the antæ or pilasters are similar to those of the columns, which might not have been so objectionable, had the angular volutes been turned diagonally. Probably the architect was unwilling to appear to innovate too much, and therefore made a sort of compromise with the taste of his countrymen; and considering what exceedingly grotesque fancies the eye is accustomed to in Italy, the whole of this design must be allowed to be exceedingly chaste."—Vol. I., 248.

tombs of Italy. For the better consideration of our subject we will divide it into two parts; giving our first attention to those objects which whether in marble or stone (bronze being with us quite beside the question) are so defaced, or so converted to other uses, as to have lost all trace of former beauty and original appropriation; and next, to those whose existence still attests the glory of the persons to whose honour they were erected, and which consecrate the historical facts they represent.

Of the first class are the tombs of Augustus and Hadrian at Rome. The plunder of nations was lavished upon them; and their great originators confidently relied upon their preservation for posthumous fame. The descriptions by ancient writers attest the elegance and richness of these mausoleums; doubtless it was expected that even the barbarian hand would shrink from the disgrace of injuring so much beauty. But ask at this day of the passing Roman the occasion of the erection of these edifices, of which the ponderous remains yet encumber the earth. He knows the one only as a fortress that awakens all his fears; and the other as the scene of his present frivolous amusements. The castle of St. Angelo awakens no recollection of the glories of Hadrian; and the area dedicated to "le giostre" and the exhibition of fire works, calls up no patriotic feeling for the memory of Augustus. Could their immortal spirits witness this desecration of their tombs and the degeneracy of their descendants, could they know that the sumptuous pile which they had looked upon as the safe receptacle of their mortal remains, and the visible object of a people's admiration to all distant times, should not even convey their names to posterity but through the medium of the antiquary,—how would they grieve at having thus employed the plunder of the world, and for such purposes taxed the genius of their most able architects.

But we think we can discover the cause of this destruction in the size and nature of the buildings. Too large to be suffered to remain useless, and their parts too numerous and too serviceable to remain inviolate, they have been robbed of their characteristic enrichments to adorn other erections, and their bulk has allowed them to be converted to other purposes. We cannot therefore too strongly impress upon our readers, the great mistake that either bulk or solidity will insure durability; in the sense in which we would now regard it, these two qualities are essentially opposed to it. We never see the colossal arch at Hyde Park Corner, but we imagine the hero of a hundred battles from his mansion opposite regarding it as a good position for a battery; and contemplating the command it must give in the event of foreign invasion or civil commotion, of the several roads and large open spaces by which it is surrounded. We can imagine too, with what little ceremony he would under such circumstances tumble over an equestrian statue he might find thereon, encumbering his position; and plant his cannon in its stead. We know that Cleopatra intrenched herself in one of the gates of Alexandria; and several of the triumphal arches of Verona appear to have been chosen, from their strength and position, for fortresses. To make these erections available, they have been perforated by the besiegers for the purposes of musketry; and the assaults of the besiegers have removed every vestige of art or ornament from their surfaces.

It would be useless and tedious to carry this part of our subject further;—let us therefore now apply ourselves to the consideration of those monuments, which after the lapse of ages still convey in intelligible terms the cause of their erection; and inquire why in the midst of the ruin that surrounds them, they alone have escaped destruction. Of these the most ancient are the Obelisks of Egypt. Formed either of granite or porphyry, the hieroglyphics cut slightly into the surface, they are by the researches of modern science as intelligible now as when first erected, and the volume of four thousand years ago is opened to our times.

Next in order are the monuments of Greece. Of these the most perfect are in Athens, a city often overrun by civil commotion, at length laid prostrate under the galling yoke of foreign enemies, and retained for centuries in the most oppressive slavery. Yet at this day may be there seen, the Choragic monument giving immortality to Thrasyllus by whom it was dedicated, and to the several other parties who assisted in the ceremonies; while the date upon it, cut with the several inscriptions into the marble, fixes its erection at three hundred and eighteen years before the Christian era. The Chroragic monument of Lysicrates, by the same means brings before us at a distance of more than two thousand years, the names of Lysicrates, Theon, Evaenetes, Lycidas; placing them on the same base with Demosthenes, Apelles, and Lysippus their great contemporaries. We could multiply these Grecian examples;—but we now turn our attention to Roman remains.

We have inquired of the passing Roman the occasion of the erection of the castle of St. Angelo, and the destination of the Palazzo Vivaldi; and we have heard their presumed reply. Let us address the same question to the loiterer in the Piazza Colonna or the Piazza Trajana. He will immediately inform us of the dedication of the columns that adorn them; he can indeed scarcely be ignorant of it, for if unequal to reading the inscriptions, he cannot mistake the bassi relievi that wind round them. Pass on to the Forum. Inquire the name to whom the arch at the base of the capitol is inscribed;—every boy can tell you. Go forward to the arch of Titus, observe the bassi relievi that enrich it, and the history it hands down; see the small opening on its side to allow the passage of the Jews, without distressing their feelings by forcing them to pass under a monument erected to perpetuate their degradation, and enriched with sculptured representations of their defeat. Under it sits a mendicant, counting his beads and imploring charity. Inquire of him, and he will tell you its history. Ignorance indeed is impossible; for the sculpture speaks all languages. He points to it, and abject as he is, he feels with exultation that he too is a Roman; and cherishes a feeling of the honourable distinction his country once maintained among nations. Further on is the arch of Constantine;—only to elicit the same observations.

From this analysis, we may fairly draw the conclusion that there are three forms which may be depended upon to perpetuate public services by visible representations;—namely, the Obelisk, the triumphal Column, and the Arch; the latter being of a volume that will not allow it to be desecrated to other purposes. The bronze statues placed at their summits may disappear, but as the mass of sculpture and inscriptions are cut in the stone or marble, they will consecrate to a very distant day the occasion of their erection.

These considerations apply more particularly at the present time; and as we can imagine no tower too lofty, no colossus too vast to typify the great exploits of the Duke of Wellington, so it is in the wish that that fame so dear to every Englishman should be, not only *worthily* but *lastingly* commemorated, that we give our attention to it. That the latter object will not be obtained by the proposed equestrian statue, we think we have clearly proved; whether the former intention will be realized we are unwilling to discuss; but upon the *principle* of the selection of the sculptor we must be allowed to say a few words.

It cannot be denied that every artist has the fullest right to publish his ideas, and to endeavour through his friends to influence the public to carry those ideas into effect. Such was the mode by which that extraordinary man Barry originated and carried out the magnificent works that decorate the great room of the Society of Arts in the Adelphi; works unhappily too little seen, and the greater publicity of which would do much for the mental and moral improvement of the public.

Had Mr. Wyatt *originated the idea and brought forward a model*, and his friends formed a committee for the purpose of recommending *that identical design* to public notice, we cannot imagine that any one could reasonably have objected to any part of such a proceeding, nor do we suppose that under such circumstances any other party would think of appropriating the intention, or of endeavouring to supersede the original promoter of it. But in the case alluded to, no such example was followed. A public meeting was called; a noble duke, the patron of Mr. Wyatt, took the chair, surrounded by gentlemen who had been most prominent in their endeavour to place Mr. Wyatt above Sir Francis Chantrey. At that meeting no whisper escaped respecting the artist; the parties were called upon to subscribe for a memorial worthy the object of commemoration; and the subscription filled, as every subscription would fill for such a purpose. But the next meeting was decidedly of a less pure character. Assembled in the drawing room of the particular friend of Mr. Wyatt, a resolution was moved by a noble lord so unexpectedly, that no one was prepared to oppose it. If a slight attempt were made to bring forward the merit of other sculptors, it was soon smothered in the burst of approbation from one of the assembled party, who unceremoniously placed Mr. Wyatt far above Sir Francis Chantrey and Sir Richard Westmacott;—and would doubtless, *had he ever heard of such a name*, have made no exception in favour of Phidias himself. No mention was made of Baily, Lough, Carew, Campbell, Gibson, the younger Westmacott, or other sculptors;—all of whom by works of extraordinary talent and beauty, would seem to command some notice. We therefore think that the appointment has been *contrary to principle and precedent*, and the selection of the material *contrary to the conviction of experience*.

In conclusion;—fitness should govern everything: it should regulate the expenditure of the King equally with that of his lowest subject; it should determine the dimensions of the palace and the cottage; and alike distribute the embellishments of the one, and the convenience of the other. It should apportion the strength necessary for the durability of the fortress, and for the slight construction of a temporary erection. It should in all cases look to its object; and in the instance under discussion, fitness would at once dismiss metal, and

confine a monument of marble or stone to such forms and dimensions as experience has proved to be alone effective for its purpose.

J. H.

P.S. Since penning the above we have had the pleasure of seeing a statue of Earl Grey in *Portland stone*, executed for the town of Newcastle upon Tyne by E. H. Baily Esq. R. A. The artist has given it a very thin coating of wax, and from the opinion of chemical friends, is sanguine in the hope that the operation of the air and smoke will be effectually neutralized by the application.

ON THE CONSTRUCTION OF SKEW ARCHES.

Fig. 1.

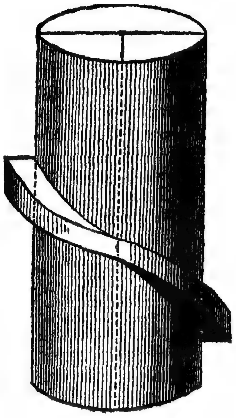

Fig. 3.

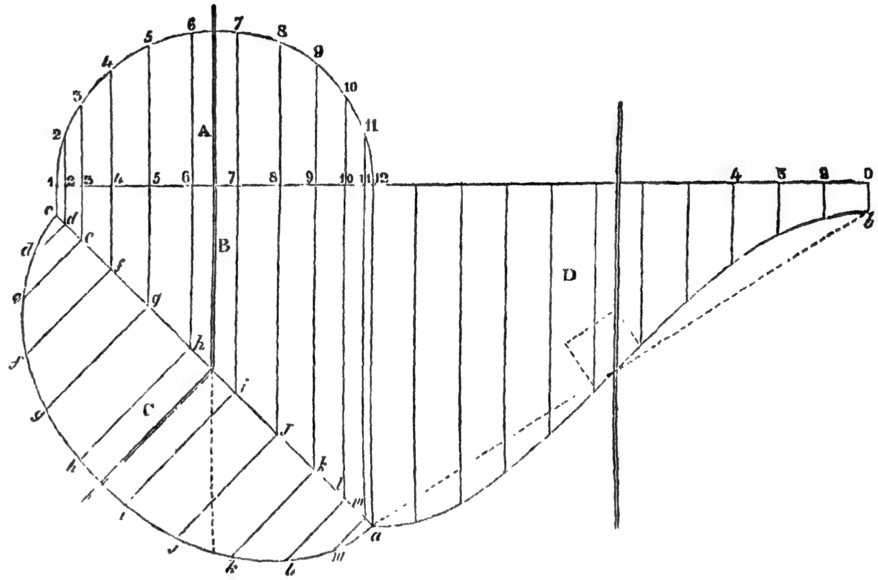

Fig. 2

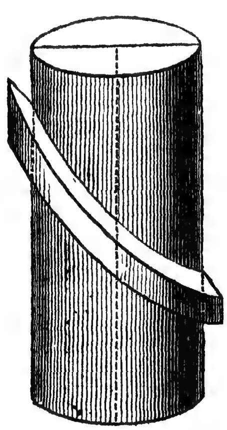

Fig. 4.

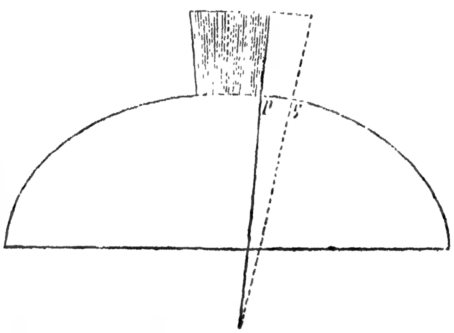

Fig. 5.

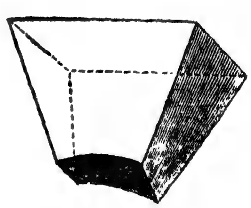

Fig. 6.

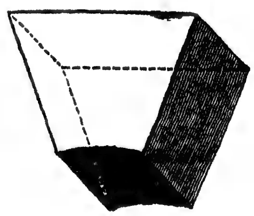

Although the construction of skew arches has of late engaged the attention of many practical men, and various essays have been written upon the subject, yet I am not aware that any of these have been sufficiently simple to enable the workman to set out a skew arch without considerable difficulty. One of the leading articles upon this subject was written by Mr. C. Fox, and read before the Institute of British Architects more than two years since. It was subsequently published in the Philosophical Magazine for April 1836; and afterwards in the Architectural Magazine for the following June, where it was mentioned in terms of considerable approbation. As this essay contained many erroneous ideas, which tended rather to confuse than to simplify the subject, it is perhaps a matter of some surprise that its contents have not been answered before. But I am not aware that any attempt has been made in any philosophical journal to point out its errors; on the contrary as far as I have been able to ascertain, the same ideas have been imbibed by many subsequent writers.

In the present article I shall endeavour to point out the leading error in the essay referred to, and likewise attempt to render the subject of sufficient simplicity to suit the most ordinary capacity.

Mr. Fox states in the first place, that a skew arch is really a square threaded screw wound round a cylinder; and with this position in view he proceeds to explain the mode of constructing the arch;—all of which is unfortunately wrong, as a skew arch is *not a square threaded screw;* and indeed it bears but little analogy to it.

The traverse of a square headed screw, is formed by a straight line wound round a cylinder, every part of which line cuts the axis of the cylinder at the same angle; and when thus wound round the cylinder it presents to the eye the appearance of a spiral and not of a straight line. A skew arch on the contrary is formed by a *spiral* line wound a cylinder, every part of which cuts the axis of the cylinder at a *different* angle,—the angle being greatest at the key stone, and least at the springings; and when thus wound round the cylinder it presents to the eye the appearance of a *straight* line. If a cylinder be cut in the direction of the thread of a screw, the section will be an ellipse, but the surface of the section will be waved and not level. If a cylinder be cut in the direction of a skew arch, the section will be an ellipse, and the surface of the section will be quite level. In a square threaded screw, the side of the thread forms what would be termed the face of the arch, and is always at right angles to the axis of the cylinder; and the angle which the thread itself forms with the axis is continually changing as the parts of the thread become more remote from the centre. But in a skew arch, the key stone alone of the face of the arch is at right angles with the axis of the cylinder, every part of the face of the arch forms exactly the same angle with the axis *when viewed from above the arch*, and the springing stones of the arch will be found on one side to present an obtuse and on the other an acute angle to the axis.

This description will be rendered more simple by a comparison of the diagrams figs. 1 and 2. Fig. 1 represents the thread of a square threaded screw wound half way round the cylinder, and fig. 2 a skew

arch likewise carried half way round the cylinder; the difference between these two will be readily perceived.

From this statement it will be apparent, that the intermediate development of which Mr. Fox speaks, is quite unnecessary; as every part of the thickness of the arch crosses the axis of the cylinder at the same angle, the approximate line (that is a line joining the two extreme points of the spiral line as *a b*, fig. 3) is always at the same angle, whether taken at the top, the middle, or the soffit of the arch.

In endeavouring to explain the method of ascertaining one of the most important parts of a skew arch, viz. the twist of the beds, Mr. Fox has likewise introduced a problem which, however simple it may appear to himself, is not certainly very intelligible to a working mason; at least the same result may be obtained by means much more certain and less complicated. In support of this statement I shall merely endeavour to show the most simple method of constructing a skew bridge.

The diagrams figs. 3 and 4 represent all that is necessary for this purpose; the angle here chosen is 45 deg., but the same rule will apply to any angle whatever. Let A fig. 3 represent the section of a skew arch, cut at right angles with the abutments; and B the plan of the same, the angle being 45 deg. Divide the circumference of the circle A into as many equal parts as there are intended to be stones in the arch; and from these points draw the lines 1, 2, 3, 4, &c. parallel to the sides of the arch; at the points where they intersect the line *a c*, which is the face of the skew bridge, draw the lines *d*, *e*, *f*, *g*, &c. at right angles to the line *a c*. Then take the length of the lines 2, 2; 3, 3; 4, 4, &c. and apply them to the lines *d*, *e*, *f*, *g*, &c.;—then draw the curve *c d e*, &c., through all these points, and the figure C will be the part of a skew arch constructed upon the semi-cylinder A at an angle of forty-five degrees. D represents the form of the soffit of the arch, and is equally simple in its construction. The line 12,0 is equal in length to the circumference of the semi-cylinder A, and divided into the same number of parts by lines drawn at right angles thereto. If the length of the lines 1, *c*; 2, *d*; 3, *e*; &c. be set off on the corresponding lines 2, 3, 4, &c., then a line drawn through all the lowermost points will form the spiral line *a b*; and the figure D if bent into the form of a semicircle, will form the soffit of a skew arch cut to the angle of 45 degrees. The dotted straight line *a b*, which connects the two extreme points of the spiral line is the nearest approximate to it that can be obtained by a straight line; and all the soffits of the stones should be drawn at right angles to this dotted line, by which means the thrust of the arch will be exerted in the true direction.

Having thus obtained the forms of the soffits, the next thing to be considered is the twist of the beds. In the skew arch, the beds of the stones are not parallel throughout, as is the case with a square arch. As every stone crosses the axis of the bridge at a certain angle, one part of the stone must necessarily be higher up on the arch than the other; and as every part of the bed must point to the axis of the bridge, the beds will, when properly worked, exhibit an appearance similar to a board which has twisted or warped, the twist being greater or less in proportion to the obliquity of the arch. This angle is easily obtained as follows. Let fig. 4 represent the front of a skew arch; the front of the key stone, the dotted soffit of which is shown at D fig. 3, is here indicated by the shaded surface; and the back of the same stone is shown by the dotted outline beside it. The distance from *p* to *q*, fig. 4 is the difference between the distance of the front and back of the stone from the centre or highest part of the arch. If two lines be drawn through these points, as nearly as possible at right angles to the curvature of the arch, the angle formed by their intersection will be the actual wind of the stones.

Figs. 5 and 6 are merely introduced to give to the workman some idea of the difference between the stones of the skew and a straight arch; fig. 5 being the stone of a skew arch, and fig. 6 of a straight one.

In order to understand this subject accurately the following considerations ought never to be lost sight of. First:—the actual thrust of a skew arch is in the direction of the spiral line, and the beds of the stones ought always to be at right angles to this line as nearly as possible; as however the approximate line joins the two ends of the spiral line, and cuts it in the middle, if the stones are placed at right angles to this line, it will be quite sufficient for all practical purposes: as any obliquity in the thrust on one side is counterbalanced by a corresponding obliquity of the other side in an opposite direction. Second:—the face of a skew arch whose centering is part of a cylinder, will always be part of an ellipse, and the fronts of the stones must therefore be drawn to a right angle with the curvature of the arch, as in any other elliptical arch, and not to one centre as in a circular arch. Third:—the beds of all the stones ought always to point to the axis of the arch; which axis will be the centre of the circle of which the surface of the centering is the circumference. C. L. O.

(To be continued.)

HISTORY OF SUSPENSION BRIDGES.

In reading some time ago a book in my possession entitled "*Papirii Massoni descriptio Fluminum Galliæ, quæ Francia est.*" *Parisiis* 1678, I found amidst a considerable mass of topographical information which to the engineer is always interesting, a notice of three hanging bridges over the river Charente. From the earliness of the date and the likelihood of the bridges having been made some ten or twenty years before the book was printed, I am inclined to believe that the suspension principle had been *commonly* adopted on the continent of Europe at an earlier period than is perhaps generally supposed. Drewry indeed, on the authority of *Davila*, states that Charles IX. employed bridges of cordage at the siege of Poictiers, towards the close of the 16th century. But as Papirius Masson does no more than mention *en passant*, that such bridges existed on the Charente, without giving any of the details of their construction, or saying anything to lead the reader to suppose that they were at all uncommon in his days, we must infer that the "*pontes pensiles*" as he styles them, were then usually resorted to in crossing deep ravines and such other places where stone or wooden bridges could not easily be erected.

In many parts of the book, tolerably minute accounts are given of wooden and stone bridges; but of the hanging bridges no details whatever are given. That they were not made on a large scale, seems probable from the description given in the following quotation of the places where they were erected. "*Tres enim pontes pensiles ibi sunt; unus quo itur in hortos, alter in pratum ingens, tertius in sylvam partim cæduam, partim non; quæ loca circuitu aquarum ejus fluminis junguntur.*" These Bridges were on the "*Carantonus*" (which is the modern Charente), between Jarnac and Cognac, towns situated on its banks, and what is curious, within 65 miles of the town of Poictiers, the spot where they were first used in Europe. There is also an account of Charles IX. having fought a battle at Jarnac. That *pensilis* refers solely to suspension bridges, is evident from the author's having in no other instance spoken of a bridge without distinguishing it by the title *lapideus* or *ligneus*.

* —— *

FUEL FROM COMPRESSED PEAT.

We last autumn called the attention of the public to this, which we then considered and described as an invention of great national importance, by Lord Willoughby de Eresby. At that time we were perfectly satisfied with the experiments we saw tried, and felt convinced that, whenever this simple operation came to be applied in the wilder districts of Scotland and Ireland, it would be found to be a most powerful means of improvement and civilisation. Since then, the noble lord has been sedulously occupied with the improvement of the machine; and a perfected instrument was lately exhibited at work in the manufactory of Mr. Napier, the engineer, York-road, Westminster-bridge. A number of noblemen and scientific and foreign gentlemen, interested in the success of such a discovery, were present on the occasion; among whom were Lord Cadogan, Lord Clare, Lord Glengall, Lord Boringdon, Mr. Macdonell (Antrim), Mr. Cornwall, &c. In their presence the common moist and wet peat was put into the chamber, and compressed by a lever (longer than that formerly employed, and consequently more powerful), the water running abundantly through the channels of the machine. The specimen was then taken out and shown to be reduced in size, and confirmed in solidity. Lord Willoughby proposes not to apply a second pressure immediately, but to go on with single actions, and leave the peats for some twenty-four hours, to acquire greater consistency and to dry. The internal wet will, in this time, be brought to the surface; and then, when the material is submitted to the second and final operation of the machine, it will become more hard and free from moisture than if both processes had been employed closely together. Of this, convincing evidence was afforded in peats which had been pressed two days previously, and were perfectly dry, heavy, and consistent; and some that had been preserved since last year were scarcely to be distinguished from coal. Every person present expressed great gratification at seeing the principle of this invention so satisfactorily demonstrated, and its practice shown to be so easy and certain. Nor can we wonder at this, when we consider what effects it is calculated to produce. Here is a fuel superior to coal, for the manufacture of the finest cutlery;—probably from being without sulphur. Here is a fuel calculated to produce superior comfort in every cottage, hut, cabin, and shieling throughout a very large portion of the British empire. Here is a fuel that can always be obtained by the lowly population of these districts, with infinitely less cost of labour and time than the mere cutting and drying of turf or peat. Here is a fuel which, used in lime-burning, may carry the blessings of agriculture into places hitherto utterly barren and incapable of cultivation; and a fuel which, by its application to fires and furnaces, working machinery, or raising of steam, may convert desert tracts into hives of manufacturing industry. Feeling and foreseeing these things, we think it impossible to over-estimate the benefits that are likely to accrue from this mighty, though simple invention. It will now be practically tried in many lands, both in Scotland and Ireland; and, like all other great improvements, when once planted, and its advantages witnessed, the example will soon spread, and we shall see the face of the country changed by this one most obvious and efficacious operation.—*Literary Gazette.*

Roman Road.—In pursuing the excavation in High Street, Lincoln, for the purpose of laying a tunnel from the Butchery to the river, the workmen lately bared a portion of the old Roman road. It is nearly a yard below the present surface of the street, and great difficulty was experienced in breaking through it. It seems to be a composition of lime, ashes, and stone, and is congealed into one solid mass, about a foot in thickness, and as hard as iron.—*Boston Herald.*

REPORT ON THE ERECTION OF A SAFETY FISHING HARBOUR
IN TRAMORE BAY, COUNTY OF WATERFORD,

By William Bald, F.R.S.E. M.R.I.A. &c. Civil Engineer.

The Lady cove, where the safety harbour is proposed to be erected, is situated on the Western side of Tramore bay, about five furlongs S.W. by S. of the town of Tramore, which lies close on the edge of the N.N.W. corner of the bay. (C, in map No. X. p. 256.)

The Bay of Tramore has been one of the most destructive to man, and also to ships, of all bays on the shores of the British empire; scarcely a winter passes but ships are wrecked and lives lost,—sometimes so many as five ships have been wrecked in one month. The waste of life and property within this dangerous and terrible bay, is such as to exceed that in any other to be found on any part of the shores of the British isles. History can no where hardly record a more melancholy event than that of the shipwreck of the Sea Horse transport, on the 13th January 1816 in the Bay of Tramore, and within one mile of the shore. She was bound to India, and had on board a part of the second battalion of the 59th regiment; of which perished 264 non-commissioned officers and privates, also Lieutenant Allen R.N., 15 sailors, 71 women and children. Only four officers and 26 soldiers and seamen survived this awful catastrophe, out of a crew composed of seamen and passengers amounting to 362 souls.

The commercial and shipping interests of the United Kingdom, call imperatively on the executive of the country, that this bay which has entombed so many valuable men, and property to the amount of hundreds of thousands of pounds sterling, should be deprived of its power of destruction by the erection of an Asylum, or Safety Harbour. The position of Tramore Bay, on the Southern coast of Ireland, by which so many ships pass and repass continually from the sea-ports on the West of Great Britain, bound to North and South America, and the East and West Indies &c. &c. further points it out as a most eligible place for a Safety Harbour. It has frequently been mistaken by mariners for the entrance to the Harbour of Waterford; and such is the power of the indraught and run of the sea into Tramore Bay, that ships falling within its headlands have seldom been known to get out.

It now becomes necessary to describe the Bay of Tramore, so remarkable for the destruction of lives and property.

The Bay of Tramore is about 2½ miles long by 2 miles broad; but behind the front strand of this bay lies a large plain of sand and mud, called the back strand, 2 miles long by 1¼ mile wide, and entirely covered at high water. The tide of flood flows through the strait near the ferry of Rhineshark with a rapid current, and fills the interior bay, producing an indraught into the outer Bay of Tramore destructive to the mariner who has the misfortune to enter it. The breadth of the strait near the ferry of Rhineshark, is at high water about 280 yards, and at low water tide about 90 yards. The front strand of Tramore Bay consists of a sandy beach of 2¼ miles in length; the rabbit warren or Burrow, situated on the Eastern portion of the strand, consists of elevated sand hills extending along the coast for 1¼ mile. The Western part of the front strand is low and covered with shingle and sand. The Western side of Tramore Bay, taken from the town of Tramore to Newton Head, bears S.W. by W. ¼ W., is in length 2 miles and 2 furlongs, and consists of an iron bound shore from forty to eighty feet in height, formed of compact indurated masses of grey Wackie rock, in beds nearly vertical, and running parallel with the coast. On this side of Tramore Bay is situated the Lady cove, which is about five furlongs from the town of Tramore. On this side of the bay also, is situated Ough a Iskey, or the fishing cove, and also Newton cove, lying close to it, which are distant from the town of Tramore about 1½ mile. These coves are creeks formed out of the steep cliffs by the action of the sea; none of them in gales of wind afford any shelter to boats. There are three boats belonging to Newton cove, and 12 boats to Lady cove; all these small craft require to be drawn up on the land beyond the reach of the sea. Such is the very unprotected state of the best sheltered creeks to be found on any part of the shores of Tramore Bay, except the inner pool of Rhineshark.

The Eastern side or shore of Tramore Bay is two miles long, reckoning from the strait or ferry at Rhineshark Pool, to Brownstown Head; and the general bearing is S.W. by S. At low water this shore, along the Rhineshark entrance within the bar, consists of sand; it extends in length 1 mile 2 furlongs, and from the bar of Rhineshark to Brownstown Head about ¾ of a mile; and consists of a rocky exposed coast.

The Harbour of Rhineshark has been formed and maintained by the scouring power of the water of the Back Strand. Within the strait near the ferry is a pool of from 2½ to 4 fathoms deep at low water, which is sheltered by the Burrow strand from the prevailing gales and the run of the sea; this is properly called Rhineshark Harbour. There are five hookers and 24 small boats belonging to this harbour and the upper inlets; these hookers are about 12 tons each, and are employed in fishing; the 24 small boats are rated at 3 tons each, and are principally employed in carrying in manure and sand from the outer bar to the interior. This harbour is bar-mouthed, and on the bar at low water there is not more than from 3 to 4 feet depth of water. The entrance channel is narrow and difficult to navigate, except by pilots well acquainted with it; there being neither beacons nor buoys to mark the channel where it is navigable. The prevailing South Westerly winds blow directly into the entrance of the harbour, causing a dangerous run of sea, and making it extremely difficult to either small vessels or fishing craft of any kind to get out.

The Bay of Tramore, in extent may be taken at five square miles, and is completely open and exposed to all gales of wind blowing from South East to South West. The depths of water in this Bay commencing at its entrance are 10, 8, 6¾, 4, 3, and 1½ fathoms within half a mile of high water mark on the front strand. The Pollock rock lies within a half mile of the head of the bay, and Eastward of the middle of that part of the bay about half a mile. The bottom of Tramore Bay is in parts foul and rocky, so that cables are frequently cut, and ships lost. On Brownstown Head there are two towers; and on Newton Head there are three towers. These towers are 60 feet high each, and are white-washed, so that they can be seen in clear weather at a considerable distance seaward, to warn mariners of their approach to this dangerous bay. The captain of the Grecian merchantman from the West Indies, bound to Liverpool, declared that he mistook Tramore Bay with the the towers on its head-lands for the entrance to Waterford Harbour; his ship consequently was carried in by the pilots to Rhineshark, from which harbour she was obliged to be towed out by a steamer, and taken round to Waterford. The front strand of Tramore Bay, at the Western end is much less covered with sand than at the Eastern, and the sand appears to be accumulating on the Eastern side. The cause of this in my opinion is, that the run of the sea is much heavier from the Westward than from the Eastward; this added to the strong tide current setting into the back strand through the Rhineshark strait, carries all the loose moving sand towards the Eastern side of the bay.

It appeared upon a careful examination of the West side of Tramore Bay, between Newtown Head, and the town of Tramore, that the Lady cove is the most eligible place to erect a small safety fishing harbour. The Lady cove can be more safely approached and landed at by boats when the ground swell sets in, than either the fishing cove or Newtown cove. But it is to be observed that when the swell is great, it is impossible to land on any part of this coast; and it is generally both dangerous and difficult to do so, when there is anything like a run of high sea, because there are no works of defence erected upon any part of this shore to afford shelter or protection to boats to land during stormy weather, nor is there an artificial harbour of any kind, on any part of Tramore Bay, comprehending an extent of 14 miles of coast. The Lady cove, is a small open bay, surrounded by rocky cliffs and steep grassy banks. At low water it presents an area of 300 feet in width by 250 feet in depth, bounded at high water line by a beach of shingle and stone; and the remainder of the surface is covered with the rock down to low water mark. In the centre, the fishermen have cleared away a space of rock of 150 feet in length, by 24 feet in breadth, extending from high to low water line, for their accommodation in landing the boats; which for safety they are obliged to draw up above high water mark upon a road ending at the head of this little bay. Along the South side of the road runs a small stream which falls into the sea, within the proposed harbour.

At low water the Lady cove presents an uncovered rocky beach for a breadth of from 140 to 200 feet, on which the sea has full room to expand itself, without rebounding back and producing those dangerous swells in gales, which are always found to take place when the coast line of the water is terminated by a perpendicular cliff. Boats have therefore landed at low tide at the Lady cove, during heavy and dangerous ground swells, when they have found it impossible to do so, at either the fishing cove, or Newtown cove; because those coves are narrow and bounded by high rocky cliffs against which the action of the waves produces those high and broken seas which swamp and overwhelm boats or small craft in attempting to land at them.

I propose to construct a Pier on the South West side of the Lady cove, as described drawn and delineated in the drawings which accompany this report. The pier (see Fig. 1) is to run out for a length of one hundred and forty feet S.E. by E. ¾ East, then in a direction N.E. 85 feet, where it will terminate a little beyond ordinary low water mark. This pier will protect the space inside intended for the harbour; because by examination of the small chart, it will be seen that the Lady cove is open only to gales blowing between S.S.E. ¼ East, and S.W. by S. ¾ West; the first is the bearing from the Lady cove to Brownstown Head, and the latter the general bearing of the coast lying to windward of it. The breakwater is to be at its base 90 feet broad; with quay walls inside, rising 8 feet above high water spring tides. Seaward it is to be armed with a heavy pavement, set in a concave curved parabolic form, commencing at high water line, and extending to the top of the storm parapet; then from high water line to low water line, the sea-pavement is to be of a convex elliptic form as drawn and described in the transverse section delineated in Fig. 2. The parapet is to be six feet high, and six feet thick; and its windward side will form the upper terminating curved portion of the breakwater glacis, on which the run of the high sea will fall and play in stormy weather, blowing from between S.S.E. ¼ East, and S.W. by S. ¾ West, being about 5¾ points of the compass, to which it will be exposed to the force and run of the ocean, during storms and gales of wind. I am quite aware of the heavy and high run of the sea into this bay, and its destructive power; but I am also equally certain and convinced that it is practicable to construct a permanent pier here, that shall be able to resist the sea, and form an excellent small Safety Harbour.

The sectional form I have given to the proposed breakwater, nearly resembles the shape which the celebrated Cherbourg Breakwater in France *took* after being many years exposed to the full and unlimited momentum of the ocean, and encountering during that period repeated gales and severe storms. This is the form which nature in deep water will assign to such masses of heavy matter exposed to the roll of the sea; it is therefore the best shape to be adopted where marine works are to be constructed, which will have to resist during high gales and storms, the whole force of the open ocean.

It is proposed to cut out the whole of the rocky floor of this intended harbour, which lies between the pier, and the small boat channel cleared out by the fishermen; the rock taken out is to be packed into the interior filling of the breakwater; and the remainder of the filling may be taken from along the cliff which extends from the root of the proposed pier to the end of the present road terminating at the head of the bay. If the excavation be judiciously executed, and kept above high water line, a good roadway 12 to 15 feet wide may be made along this part, connecting the proposed pier with the present existing old road leading to the town of Tramore, which contains a population of 1,600 souls and is rapidly increasing. To connect the town of Tramore with the new proposed harbour by a new level line of road, would be a most useful and desirable work, the old road being extremely hilly and very much elevated. The distance from the proposed harbour to the town of Tramore along the cliff is about six furlongs, and the proposed road would form one of the most beautiful and interesting road works yet executed in Ireland; while its great usefulness would extend to all classes of society, by its being perfectly level, and affording an easy draught to the drawing of loads of all kinds coming from and going to the harbour. This road would be useful in opening up many improvements connected with the rising town of Tramore, the Brighton of the South of Ireland.

I have in Fig. 1 delineated a second arm or pier to the proposed safety harbour; but as the execution of this part would when combined with that of the seaward pier, amount to a sum which could not perhaps be reasonably expected to be procured at present, I have refrained from putting the amount of its expense into the estimate; and more particularly because the experience of protection arising from the construction of the pier now recommended, will become more fully known, and the further extension will proceed upon a more extended knowledge of the subject in all its details than can at present possibly exist.

During my second examination of the Lady cove, I had the kind assistance of Lieutenant Scuddamore of the Waterguard service, who resides there, and who is thoroughly acquainted with the place in all its maritime details and capabilities; and as far as I consulted him, he coincided in opinion with me, regarding the eligibility of Lady cove, as being the best place for the erection of a small safety harbour, the practicability of its execution, and also the very great benefit that would be derived from it as a harbour for the extension of the fisheries on this portion of the coast of Ireland, so extremely productive of all kinds of fish. Within the pier at ordinary high-water spring tides, there would be a depth of eleven feet of water.*

In the event of a pier being constructed at Lady cove, I do not apprehend that there will be any silting up; because the whole beach, to seaward and windward, consists of a clean rocky shore. There is also a stream of water continually running through the harbour, and which is considerable in winter, offering a scouring power of some magnitude under proper management, if such should at any time be required.

There can be no doubt that the erection of a pier, for the protection of fishing boats at the Lady cove, would extend the fisheries very much on this part of the coast of Ireland; because as there would be safety and protection, boats of a larger size would then be procured. There lies immediately off Tramore Bay, the best fishing ground on the South coast, where at present when the weather permits, boats from Waterford and Dungarvin are constantly fishing. The Nymph Bank, which lies off this part of the coast, would open an inexhaustible mine of wealth to the fishermen of Tramore, who would be enabled to supply Waterford, and all the interior towns with an abundance of fish. I am so thoroughly convinced of the success which would attend the construction of this little safety harbour, that in place of 12 small boats (the number at present belonging to the Lady cove) I am confident there would be hundreds; and I have no doubt there would be in a short period not less than 400 persons employed in fishing, instead of 48 the present number. I am further convinced, that this little harbour would give birth to a considerable import and export trade, which does not at present exist; by which the trade and traffic of the country would be much increased.

In concluding, I cannot but express my regret that it has not fallen to my lot, to advocate the erection of a larger harbour on this coast, than the small one which I have now reported on. The disasters on this coast have been so numerous, and so frightful, that I am impressed with the necessity of the erection of an Asylum Harbour of magnitude in deep water, near the entrance on the West side of Tramore Bay; and the national necessity for such a work has induced me to quote a paragraph from a report of mine on the erection of an Asylum Harbour at the Skerries, on the East coast of Ireland, which is however much more applicable to the Bay of Tramore, than to any other part of the coast of Ireland.

"The erection and formation of these maritime works for the preservation of life and property, would be alike creditable to the wisdom and humanity of the rulers of the British Isles." But if this be doomed to no further regard, then I may fairly quote the following paragraph. "That the subject with which they have to deal is that of human life; of the lives too of the industrious mariner whom they have severely taxed, and of the helpless seafaring stranger whom they have taxed without mercy. If they fail in this sacred duty, they will be answerable to a tribunal more solemn than that of their constituency, a tribunal where benevolence will be their judge, science their accuser, and the widows and orphans their jury."

I remain Gentlemen,

Your most obedient Servant,

WILLIAM BALD.

To Patrick William Power, Esq., and
George Lewis Smyth, Esq.

Estimate to build a safety Harbour at the Lady cove, Tramore Bay, County of Waterford.

	£	s.	d.
3333 cubic yards of rock to be excavated out of the harbour and packed into the breakwater, at 3s. 6d. per cubic yard	583	5	6
3333 cubic yards of rock to be filled into the pier and breakwater, at 2s. 6d.	416	12	6
666 cubic yards of masonry in quay wall, at 12s. per cubic yard	399	12	0
1894 cubic yards of masonry in covering and arming the breakwater, at 12s. per cubic yard	1136	8	0
333 cubic yards of masonry in storm parapet, at 12s. per cubic yard	199	16	0
375 superficial yards of paving on top of quay, at 3s. per yard	56	5	0

THE VICTORIA STEAM SHIP.

CORONER'S INQUEST.—EXPLOSION ON BOARD THE VICTORIA HULL STEAM SHIP.—OPINION OF THE GOVERNMENT ENGINEER.

Considering this inquest to be one of great importance, we attended the last investigation to watch the proceedings for the purpose of laying them before our readers; and for the better understanding of the evidence, we have given copies of the drawings produced by Mr. Ewart in his evidence, which we are enabled to do by his permission and that of the coroner. We abstain from giving the evidence of the four first days' investigation, as the whole would more than fill our Journal; those who feel deeply interested in the matter, we recommend to peruse the prior days' evidence, which will be found in most of the daily papers, and by the assistance of the drawings given in our Journal the investigation will be properly understood.

General References to the Drawings.

A—Principal flue, or fire tube.
B—Water tube.
C—Rising pipes of do.
D—Brick bridges of the furnaces.
E—Water space around the fire tube.
F—Steam chambers.
G—Fore and aft steam connecting-pipes.
H—Athwart ship do. do.
K—Water connecting-pipes; uniting each wing boiler with the adjoining midship boiler.
L—Feed-pipe.
M—Feed-cocks.
N—Outer flues, formed of bricks resting on iron plates.
O—Vent from fire tube to flues N.
P—Boiler seating of brick.
R—Furnace bars; in fig. 1, the dotted lines show the bars of the midship furnaces.
S—Chimney.
T—Man holes to water tubes.
W—Water line.
x—Steam pipes; they are so connected that the steam has free communication with all the four boilers.
r—Rupture; *rp*, Principal rupture; *s*, Detached piece; in drawing all which, it must be observed, we have for distinctness employed full lines, even where dotted ones should properly be used to denote that another surface intervenes.

On Wednesday morning, July 18th, at eleven o'clock, the inquest on the bodies of the nine unfortunate men who were killed on board the steam-ship Victoria, trading between London and Hull, by the bursting of one of her boilers, was resumed before Mr. Baker, coroner, and a jury, at the Waterman's Arms Tavern, Shadwell Dock-stairs. The investigation had already occupied four days.

Mr. L. Jacobs, the solicitor to the Hull Steam-packet Company, and Mr. W. J. Hall, the agent and managing owner, attended to watch the interests of that body.

The Coroner read over the names of the Jury, and the correspondence which had passed between him and the Home Secretary, for the appointment of a government engineer to inspect the boilers; which led to the appointment of Mr. Ewart, Engineer at her Majesty's Dockyard Woolwich.

Mr. Peter Ewart deposed that he was chief engineer and inspector of machinery, to the Admiralty. He had been so about three years, but had been intimately acquainted with the business generally for 48 years, and took the general management of the mail-packets. He examines the boilers. He often works from the designs of others, but he has been a theoretical and practical man all his life.

The Coroner asked Mr. Ewart if he had prepared any report, or intended to give his evidence *viva voce?*

Mr. Ewart said he was ready to answer any questions that might be put to him

Mr. Ewart's evidence was then taken. In pursuance of the instructions he had received from the Home office, he had made four separate examinations of the boilers. At the first visit to the vessel, he went into the stoke hole, where he received every attention from Captain Bell, who explained everything to him. He found the boilers of the Victoria so constructed that the pressure might be varied from 3lb. on the square inch, to 13½lb. The *maximum* of low pressure was 5lb., and commonly only 3lb. The boilers in the Queen's service are square, not circular. The pressure on the square inch, with the boilers used in the Queen's service, never exceeded 5lb.; the average was about 4lb., but the orders were, never to exceed 5lb. With the same strength of metal the circular boilers are stronger than the square ones if the circular are not too large.

The Coroner—Do you consider the high pressure as safe as the low pressure?

Witness—It is too general a question.

The Coroner and Jury then asked the witness several questions, but he said he could not answer such general questions.

The Foreman said, the Jury had not sufficient experience in steam-engineering to ask proper questions. It would be better if the gentleman would give his evidence by way of report.

Mr. Ewart said, he would endeavour to answer the Coroner's questions as to the relative safety of high and low pressure engines. There was a greater number of more serious accidents with high pressure engines, than with low pressure. The high pressure engines had been used in Cornwall for many years, and latterly with very little accident. He produced a drawing, but said he was not going to give a lecture; it was almost impossible to do so here. According to the construction of boilers now adopted, very few accidents had occurred. The boilers of the Victoria were nearly of an oval shape, about 6 feet 5 inches in diameter; the water spaces vary from 2½ inches at the sides, to 3 at bottom, and 6 at top. There was 9 feet of water pressing on the bottom of the boilers, making by its weight a total pressure of 17lb. on the bottom of the boilers. The water spaces of the Cornish boilers round the flues were much larger, being at least 6 inches at the bottom and 21 inches at top (*vide* fig. 9). The external cylinder of the boilers was about 6 feet in diameter, and the internal 3 feet 9 inches, leaving a water space of 6 inches at the bottom; and instead of being filled with water, a space was left in the upper part of the boilers occupied by steam. The plates were generally half an inch in thickness, and the safety-valves were generally loaded with 45lb. on the square inch. These constitute the chief differences between the Cornish boilers and those of the Victoria. He attributed the superior safety of the Cornish boilers to the difference in their construction altogether. He wished to observe that almost all the towing vessels on the river Thames have high pressure boilers, made very much upon the Cornish principle, and very few accidents have occurred to them of late years; further, he considered the water spaces of the Victoria's boilers much too small, and their plates of insufficient thickness. He found them from a quarter of an inch to very near three-eighths in thickness only. He produced a section of the boiler that burst. In the longitudinal section (fig. 1) the lower part of the fire tube had been originally straight, but was now bent upwards two feet, and torn asunder. The thickness of the plates at this part was little more than a quarter of an inch, but about 6 feet further aft, and where the iron had yielded very little to the pressure, the iron was about one fourth thicker than where the fracture was. He ascertained it by boring a hole, and the iron at that part must have been subject to nearly the same pressure as the part which burst. That was one reason he thought it too thin; the quality of the metal is good, and the boiler well put together so far as he can judge. He endeavoured to discover the cause of the want of steam during the last voyage, and he found that considerable alterations had been made in the two midship fire-places, which prevented the fires burning, from want of draught; the lower end of the bars had been raised eleven inches higher than they had previously been (as shown by the dotted lines in fig. 1), the effect of which was to reduce the draught; the fire-place of that which burst had not been altered. The water spaces of the boilers were too small for any fire, but the fire-places of the Victoria were very large. The one under the boiler which burst, is unusually so; it is capable of being urged to a very high degree of heat. The boiler adjoining, having the same relative position to the one that burst, and having the same head of water on it, is a little out of shape, but has escaped in consequence of that furnace not being capable of being so much urged as the other. In consequence of the deficiency of steam, the furnaces in the wing boilers were required to be urged to a much greater degree than before the change was made; and he had been led to conclude that the furnace of the boiler which had burst, had been urged in a much higher degree than any other. The four transverse sections in the drawing before him, showed the process of collapse; the first (fig. 4), a little behind the bridge, exhibited the upper part of the fire tube greatly collapsed. The next (fig. 5) was taken where the principal rupture was, and the tube collapsed in an extraordinary degree. The next (fig. 6) was taken 4 feet further on than the principal fracture, where there was a fracture, but not to the extent of the principal one. The next (fig. 7) about 7½ feet further back; the further end of the boiler is not collapsed. As a matter of opinion, he should say that these collapses would not have taken place in the manner or degree they had, if they had been made upon the Cornish plan.

The Coroner—We have heard a great deal about blowing the water out of these narrow interstices by excessive heat or by a lurch of the vessel.

Mr. Ewart—I do not think a lurch of the vessel would do any such thing; but that the excessive heat acting upon such narrow spaces might have caused the steam to blow the water out of some part of the water spaces, and have let the iron get red hot.

The Coroner—Would the water be forced up so as to deceive the engineer?

Mr. Ewart—No, but an ebullition would take place, especially in Thames water, which, from its violence, might certainly deceive him as to the feed cocks and gauges; but that belongs to all boilers.

Coroner—What is the cause of the collapse you have spoken of?

Mr. Ewart—The external pressure of the steam and water is greater than the plates could bear when overheated.

The Coroner—Was any gas produced?

Mr. Ewart—No, not in this case, neither was a vacuum formed; there was no oxydation of the boilers sufficient to produce any alteration of the gases. The boilers seemed new; there was a slight scale thrown off in one place, but not sufficient to produce any such effect.

The Foreman—In her Majesty's vessels, is it usual to have machinery in the engine-room by which the engineer might have control over the satety-valve?

Mr. Ewart—Yes, Sir; we never send a vessel to sea without one.

The Foreman said, he had been induced to ask this question from observing that the engineer of the Victoria had no control over the safety-valve in the engine-room, and was in a situation in which he could not relieve himself, whatever occurred, or however great the danger might be.

Mr. Ewart—The safety-valves of the Victoria are placed in a highly improper manner. They are placed at a great distance from the engine-stage, and exposed on the top of the cook-house, so as to be accessible to every one, and liable to be tampered with, which with lever weights would be both easy and dangerous. They would not, however, be affected by a collision, except in a very extreme case. In all the Government steam-boats, and those which I have had any direction of elsewhere, the weight on the safety-valve was so placed that it could not be increased without taking part of the boiler apparatus away, which must occupy much time. I examined the glass gauges and gauge-cocks, which were of the usual construction, as were the feed-cocks also. The steam-gauge was placed in a very inconvenient situation, being at a great distance from the proper position of the engineer, and at a place where its variations cannot be distinctly observed. The feed pumps are worked by the engine, and the supply regulated by the engineer. The discharge valve from the feed pumps, to get rid of the surplus water, is very well placed, where it can be seen by the engine men. When the pump is at work, this valve is always in action, and indicates whether the pump be working properly or not. It appears to be loaded from the inside. It is difficult to say whether iron has been red hot or not, except when it has been so for a long time. I saw nothing that could enable me to say whether the boiler has been red hot or not.

The Coroner—I have to ask you a very important question. Do you think all you have described might not have occurred by the turning off of the feed cocks?

Mr. Ewart—I will try to answer it. The feed cocks are all of the same height, and each boiler has one. The turning off the feed cocks occasionally, and for a short time, does not endanger the boilers, and it appears to me that in order to expose the bottom of this boiler to the action of the fire without contact of water, the feed cocks must have been shut upwards of three hours. One reason why I think the lower collapse must have taken place in the bottom of the flue as early as in any part of the

Fig. 3.—Elevation; the left hand Boiler is shown with the fire doors removed;—the second, with them in their places; the third, at a section behind them, exhibiting the bridge of the furnace;—the fourth with the bridge and bars removed.

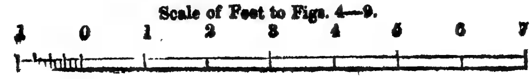
Scale of Feet to Figs. 4—9.



boiler was because it is the largest collapse; and the next because there is a second rupture, about nine feet further aft, and it appears to me that those two fractures must have taken place at the same moment, for this reason, that if one had broken first it would have relieved the other.

In answer to a question by the foreman, Mr. Ewart said they tried iron plates for boilers by submitting them to a red heat, when, if they were unsound, they would blister. Some iron was very faulty.

By Mr. Jacobs—When iron becomes heated it is softened and weaker.

By Mr. Young—It would take three hours to evaporate the water in the boiler; but I do not say that really took place. I can never believe that ten men could be so blind as to leave the cock shut half an hour, much less three hours.

Mr. Jackson—How do you account for ten men being employed in the engine-room at once?

Mr. Ewart—She has very powerful engines, and to work the valves by hand for stopping, requires five men to each engine, which is not uncommon. Immediately on the collision happening, the men were all at their post, as was right.

By the Foreman—The accommodation for the stokers is very confined indeed. There are none like it in her Majesty's service. What adds to the evil, the chimney passes through the stoke-hole, and there are no cases round the chimney, to prevent the radiation of heat. But that has nothing to do with the accident.

By Mr. Jacobs—Have often known boilers burnt for want of water; the fault was often owing to leakage; it sometimes occurs by neglect of duty on the part of the men employed.

By the Coroner—The effect of water being thrown suddenly on heated iron, if there were a great mass of it, would be to produce collapse outwards. Could not say what the thickness of the plates ought to be for high pressure engines, but the Americans had long persevered in their use, although an immense number of the most awful accidents had occurred; but of late, from the advertisements in their newspapers, he had seen that low pressure engines were becoming favourite and popular; the fact was, the American people had, at length, become alarmed.

By Mr. Jacobs—Did not think it necessary to prove low pressure boilers. Had known plates tested up to a high degree so injured by it that they were spoiled.

Mr. Jacobs—Would not that injury be almost immediately apparent?

Mr. Ewart—No, I think not.

Mr. Jacobs—Could not these boilers be so strengthened as to bear a pressure of 20lb. or more?

Mr. Ewart—It is extremely painful to me to speak upon the subject, but I must say I would not do any such thing. I would use no such pressure.

Mr. Jacobs then put a question so perfectly hypothetical that the Coroner refused to receive it as evidence.

By the Foreman—There would be a smell of burning when the water was low.

By Mr. Hall—If a vessel has been working two years with only an inch and a half water spaces, what should you be inclined to say respecting the danger of narrow water spaces?

Mr. Ewart would say nothing unless he had examined the boilers. He, however, thought if they were such, they must differ much in their construction to those of the Victoria.

By Mr. Jacobs—Had not examined the boilers that are now entire, and therefore cannot tell the thickness of their plates. Would examine them if ordered, but he should be sorry that any such duty should be imposed on the coroner and jury. (Laughter.)

Captain Bell was recalled, and asked if he heard the stokers urging each other to keep up the fires? He said he did, and that they quarrelled so much that he was obliged to check them, telling them that he did not allow such rows on board.

The ship's register, as entered at the Custom house, was here produced. It stated the Victoria to be of 538 16-34 tons burden. William Bachelor Brownlow, of Hull, and numerous other persons in Yorkshire, Lincolnshire, and London, were stated to be the owners.

Mr. Ewart then said, that as the Coroner wished to be informed on the subject of prevention, there was an easy way of discovery whether there is sufficient water in the boiler by means of a pipe, which dips to a certain depth in the water.

Mr. Hall objected, that this had nothing to do with the question before the jury.

The Coroner—I know it has not, but you do not wish to profit by anything. The Coroner and Jury do, and so do the public.

Mr. Ewart said, he was instructed by her Majesty's Government to report any plan for the safety of the public which he might be able to suggest. He then produced a drawing of a contrivance called a detector pipe, by which it clearly appeared that if there was either a scarcity of water in the boilers, or too great a pressure of steam in the boilers, or that the safety valve was impeded in its action, it would immediately call the attention of the engineer, in the first case, by a peculiar noise, and, in the last, by discharging steam from a small tube. Four of the Admiralty vessels were fitted with these tubes, and they had orders to supply them generally.

At the conclusion of Mr. Ewart's evidence, which lasted from 11 until 3 o'clock, he was complimented on the very great pains he had taken in the examination of the boilers, and his general solicitude to inform the jury.

The Jury then retired for an hour and a half, to get their dinners. On their return, Mr. Farey was called upon.

John Farey, of No. 67 Guildford-street Russell-square, stated that he was an engineer. He had been engaged in that department of science which relates to machinery and steam-engines. He had seen and examined the two larboard boilers of the Victoria. He then described the collapsed state of the flue, the fractures, one at the bottom of the flue, six feet long, and another at the side, four feet long, and these two fissures had allowed the water to be ejected with considerable violence; there was a small crack in the conducting pipe near to its connexion with the upper part of the boiler, and a small crack near to the fire-place. The water and steam issued with great violence,—that was apparent, as was shown by the brickwork being washed away. In the principal fissure above 40 rivets had been forced away. The thickness of the metal in the lower edge is only a quarter of an inch on an average, but the untorn edge is thicker by the 32nd of an inch. About nine square inches were torn away. From what he had heard of the water spaces, he should say that they were too small. In steam coaches, the necessity of lightness has led to the making of small water spaces, and it has been invariably followed by the blowing out of the water whenever the fire was disproportionate, when the iron always becomes red-hot. I think that this has placed a limit to steam coach travelling. The excessive bubbling which takes place on those occasions prevents the water being pressed upon the metal, and the consequence of this is, that steam is generated, and mixes with the water. It should be observed that these difficulties arise oftener with low pressure steam than high pressure, from the diminished bulk of the steam; and, consequently, high pressure boilers do not require so wide water spaces as low pressure to be equally secure. When he spoke of the water spaces of the Victoria being too small, it was in reference to the condition under which they worked the boilers. The fires were unusually large, and the return flues being at the bottom of the boilers, all the steam generated at the bottom of the boiler had to pass up through the narrow spaces, and, consequently, the spaces must have been filled with water and steam mixed.

The Foreman—If the supply of water had been cut off for more than the proper time, what part of the fire-tube would first become red hot?

Mr. Farey—The deficiency of water so occasioned must have been progressive, and as less and less water remained above the internal flues, it would become a mixture of more steam and less water, allowing all the upper part of the boiler to get hot, the heat being greatest at that point where the greatest proportion of steam was mixed with water, which in these boilers would not be in the highest part, because that would be kept wet by the steam and water rising on both sides.

The Coroner—You attribute the evil to the narrowness of the interstices?

Mr. Farey—That is one reason. Another is the thinness of the plates, and another the extent of the fires. I never saw any fires so large; the general size is two feet six inches by nine feet; those of the Victoria are six feet wide and nine feet long. Besides which, the boilers of such vessels are half an inch thick in metal. The pressure also was great on the Victoria boilers, being 10lb. on the square inch, while the usual class of steamers have a pressure generally of not more than 4lb., and this is the regulation in Government vessels, and amongst low pressure engines generally. While there was nothing to prevent it, competition would force the conductors of steam boats to use higher pressure, and to increase it, and consequently the greater risk would be run. There were difficulties in the way of legislating on the subject, which had been several times before the House of Commons, from the fact of there being no standard of perfection, and from a laudable fear to prevent improvements. He believed this would have been the case if any legislation had taken place on the subject 20 years ago. In France regulations had been made, but they only respected the testing of the boilers, and the consequence was that fewer accidents had happened since.

Mr. Hall—The last witness said testing was injurious.

The Coroner—Mr. Ewart said he would only use those which were strong enough without testing.

Mr. Hall—What is your definition of a high pressure engine?

Mr. Farey—High pressure engines were invented by Trevethick, who gave the name to them, and they are used for locomotive engines. Since that, Wolfe had applied the high pressure principle to condensing engines, and they were now universally used in Cornwall. A high pressure engine of Trevethick's blows the steam off into the air at every stroke of the piston. Low pressure engines worked on the high pressure principle have lately been called high pressure, and this has led to some confusion. No one will undertake to fix the point at which high pressure begins in such engines, but the extremes could not be mistaken. The low pressure engines of 4lb. on the square inch are undoubtedly the best; they are better adapted to steam vessels, and this is borne out by the Government packets.

Mr. Hall—Should you call 5lb. a low pressure?

Mr Farey—Yes, certainly.

Mr. Hall—What would you call the same engine if she was worked at 10lb.?

Mr. Farey—A low pressure engine overworked.

Mr. Hall—What would you say if it was worked at 15lb. or 20lb.

Mr. Farey—Still more overworked; and then an apparatus for the expansion of the steam in the cylinder must be provided.

Mr. Farey further gave a most minute description of the boiler that burst on board the Victoria; but as it entirely coincided with that before given by Mr. Ewart, it is unnecessary to insert it.

In answer to a question from Mr. Hall,

Mr. Farey said that high pressure engines, as applied by Wolfe, were very popular in France, and that boilers of this sort were superior to the high pressure boilers of England.

On the whole, he considered that the accident arose from a concurrence of unfavourable circumstances in the construction of the boilers, as they required very urgent fires to enable the engines to do their work; the water spaces were too narrow compared with the width of the gratings; the metal of the internal tube was too thin compared with its diameter; the load on the safety-valves greater than such a tube was qualified to work under; and the heads of water over the boilers, deficient in extent, which ought to be continuous throughout.

A discussion here took place as to the propriety of adjourning, but it was at length determined to hear the evidence of

Mr David Napier, from whose designs the boilers on board the Victoria were made. That gentleman being sworn, deposed as follows:—I reside at Blackwall, and am an engineer, and have been all my life engaged in that business. I am 47 years of age. I was brought up under my father, who was an engineer, and practised at Glasgow, where I had extensive works. I have ceased to follow the business for three years, owing to bad health. I have fitted a great number of boats with engines and machinery. I made the boiler for the Comet, the first steamer that was employed for practical purposes in Europe. I do not now recollect whether it was from my design or not. I was the sole owner of the Rob Roy, the first steamer that navigated the open seas.

Mr. Jacobs said he would put in a report of a committee of the House of Commons, in which was the evidence of Mr. Napier, relating to the employment of the Rob Roy between (Liverpool and?) Greenock and Glasgow, the first time that a steamer was usefully applied in the open sea.

Mr. Jacobs—You made the engines for the Talbot and Ivanhoe?

Mr. Napier—I did. They were the first steamers that ran between Dublin and Holyhead. I constructed the engines for the Belfast, Eclipse, Superb, and Majestic. They were the first vessels of a powerful description that completely succeeded on the Liverpool and Greenock passage. They were employed by the Government to carry the mails. About two years ago, the engines of the greater part of the sea-going vessels out of the port of London were made by me. Among these were the Belfast, Mountaineer, and United Kingdom. Several belonged to the General Steam Navigation Company. Had made boilers of the width of those in the Victoria in the water spaces. The Loch Lomond upon this principle has been plying three years, and I never heard of the least inconvenience from the width of her water spaces, and not sixpence has been incurred in repairing them. They are precisely

the same as those in the Victoria. When I went to Glasgow a month ago, I found other engineers copying them, so satisfied were they of their efficiency. Two of the Victoria's boilers are now as perfect as when they were originally made. I made them all from one plan. I am a judge of the power of the engines from their practical use. When the Victoria came up, she was working at much less power than when she went down. Horse-power was an indefinite term, and depended on the pressure of steam.

The Jury said that they were receiving a new light; steam-vessels were generally set down as so many horse-power. When a vessel was advertised of 300 or 400 horse-power, could Mr. Napier say what was meant?

Mr. Napier—I really do not know. The engines of the Victoria might be worked up to 400 horse-power.

In answer to a question by the Coroner,

Mr. Napier said that he considered the blowing out of the water from the interstices all nonsense.

A Juror—You won't make me believe it nonsense, though.

Mr. Jacobs and Mr. Hall said that was giving an opinion, and that they might as well withdraw at once.

Mr. Napier then stated that he had made the engines of the Chieftain, for the Mediterranean, with boilers of the same construction, but with only one inch and a half water space. The boilers were a little less, and nearly five feet in the tube. The fire-places were five feet wide, and of the same description as in the Victoria. The cylinders of the Chieftain were 48 inches, those of the Victoria 64 inches, and the plates of the boilers were a quarter of an inch thick.

By a Juror—Did not know that the Chieftain had been on fire, or that she was now laid up.

By Mr. Jacobs—No engineer who did his duty could be deceived by the boiling of the water. An engineer who did his duty would always keep the water at the same level, and so regulate the feed cocks as to effect that object.

By the Coroner—Did not know by whose orders the gratings were altered. He saw the Victoria coming up the river on the day the accident occurred, about 5 miles below Woolwich; the Wilberforce was astern of her, and witness was surprised to see them so close together. Considered the Victoria could beat the Wilberforce. At Blackwall the Victoria again began to go much slower; the Wilberforce was then gaining upon her. I watched them, and just above Greenwich the Victoria increased her speed. I did not see her stop at all. When she passed the City Canal I still had my eye on her, and she was then going much faster, and I saw steam blowing off, and I concluded that the engineers had been pinching the feed pipes and getting up more steam, in order to get to London first, when they saw the Wilberforce was gaining on her. I believe she would have gone to London safe, but for the collision with the brig. The engines were stopped, and the steam suffered to accumulate, which caused the explosion. The engineers were, in my opinion, neglectful of their business. They ought to have eased the safety valve.

The Foreman—That is the reason why the engineer should have control of the safety valve in the engine room.

Mr. Napier—The boilers were overheated, and then a slight pressure of steam would injure them. The engineer ought to have removed the extra weight on the lever at Blackwall, going and coming, and the accident could not have occurred. It was excessively stupid his having it on; the difficulty in backing astern was accounted for by that. Recommended plates a quarter of an inch in thickness, and that they should be tested to three times the pressure intended to be used, and if they exhibited any signs of weakness, to use increased strength. Had made a boiler for the Postboy steamer, which had worked six years without accident, and the water spaces were only one inch and a half. The Postboy was in constant use, and was of 24 horse power.

Mr. Napier then referred to his evidence respecting steam coaches, and said that he had made one, and that the cause of their failure was not the blowing of the water out of the tubes, but the great weight of the carriage on a common road. He had wasted 1,000*l.* in experiments with steam coaches. With respect to the blowing out of the water from the narrow spaces of the Victoria, he was ready to give 10,000*l.* to the poor of the parish of Shadwell if any one could prove it could happen. If the plates had been double the thickness, and they had been allowed to get red hot, the same results would have followed. The plan recommended by Mr. Ewart for discovering deficiency of water in the boiler, was used by him 20 years ago, and not found to answer in many vessels. The Cornwall land-boilers could not be used at sea. The safety-valves of the Victoria were, in his opinion, properly placed; they could not be better.

By the Jury—The Earl Grey engines and boilers were made by me. She exploded in the Clyde, and lives were lost. Her boilers were square ones, and I recommended the owners of the Victoria to have four circular boilers, for I do not consider the square ones so safe. There was an explosion on board the James Ewing. The engines and boilers of that vessel were made by me, and a loss of life ensued. The boilers of the James Ewing were not constructed the same as those of the Victoria.

The Coroner said he would read over the voluminous evidence already given by Mr. Napier, and proceeded to do so Mr. Baker had not proceeded far when

Mr. Napier said he wanted the words of the report of the House of Commons to be given *verbatim* respecting the vessels for which he had made the engines and boilers when steam navigation was first introduced.

The Coroner said, he could not take the report of a Parliamentary committee as evidence. After a long dispute with Mr. Napier, he added the words "as so reported by a committee of the House of Commons," after that part of the evidence relating to the various steam-vessels and the introduction of steam navigation into Europe.

Mr. Napier having signed his deposition, the inquest was adjourned till Tuesday, the 31st of July.

EXHIBITION AT THE ROYAL ACADEMY.

ARCHITECTURAL ROOM.

(*Concluded from page 255.*)

There are as usual several designs for private residences, yet very few to which any particular merit can be allowed on the score of tasteful design, although the buildings themselves may be agreeable enough, but owing to circumstances entirely independent of architectural quality. One of those most distinguished by this latter, ought to have been noticed before, namely 1070, "The Rectory House, Kingsworth, Hants," J. Buckler. It is a spacious mansion in the Tudor style of dark red brick, the principal portion of which forms a lofty, tower-like mass, and it has also very lofty and rich chimney stacks. The character is so well kept up that it might pass for a genuine remain of the olden time, but whether it is in consequence less eligible for the purposes of a modern residence than otherwise might have been, it is impossible to judge from a mere view. Unless too much has been sacrificed to picturesqueness of exterior appearance, it is very commendable, and emphatically old English. Although somewhat similar as far as the adoption of style goes, No. 437, "View of a Mansion to be erected near Cape Town, for Baron Van Ludwig," H. C. Vogel, is utterly dissimilar in feeling, nor is the style itself recommended by any propriety in the selection of it for the country where the building is to be erected.

No. 1144 "View with slight alterations of a Mansion in Hants," C. Miles, is also an exceedingly poor affair: it would require not 'slight' but very great alteration indeed to render it at all tolerable.

No. 1145 "Design for a Mausoleum to be erected at the Cemetery Kensall-green," T. R. M'Quoid, is a sepulchral structure displaying much elegance of taste, in a subject which is undoubtedly very favourable, as it is one where classical prototypes may be followed without depravation occasioned either by addition of what is foreign or suppression of what essentially belongs to them.

We can likewise speak very favourably of 1152 "Design for a Gothic Altar-piece," J. Taylor Jun. treated as a screen over which is seen a window, and behind which, we presume, the vestries would be placed. But we further presume that anything of this description would stand but little chance of obtaining favour with the Church Commissioners, especially when we behold them sanctioning and adopting such designs as 1157, "New Gothic Church as approved by the Metropolitan Church Commissioners, and now commencing in the New North-road, Islington, from the Designs of Messrs. W. and H. W. Inwood." This is the very consummation of paltriness,—a degree worse if possible than Messrs. Inwood's Somers-town Chapel, which we should have thought that Welby Pugin had recorded sufficiently in terrorem.

The next No., "Proposed Front for a Town Mansion," J. Bell, is upon such a scale that it does not look as if it was proposed in earnest,—at least not with any chance of being adopted for any private mansion in London. It has much more the air of being a design for a Club-house than a private residence. It consists of three series of windows, seven on a floor, all very much enriched, besides a range of smaller windows, immediately below the cornicione which finishes the elevation, and with the windows constitutes its chief decoration. There is certainly something grandiose and commanding in the general aspect; yet in our opinion it might have been equally so with a little more refinement of form; for it must be confessed that the three centre windows of the principal floor, look overdone with decoration, and even top heavy. The composition of the entrance too, having a diminutive window on each side of the door, is by no means unexceptionable. One thing which deserves to be noticed as contributing very much to the grandeur and breadth observable in this front, is the great width of the extreme piers or spaces beyond the windows.

Nos. 1162, 3, and 4, are all by Sir J. Wyatville, and the first and third represent the Victoria and Winchester Tower at Windsor Castle, the other "a Design formerly approved for adding to St. James's Palace." They do not obtrude themselves upon notice, for they are three of the smallest drawings in the room,—and so far no one can grudge them the space they occupy; and they are likewise those which make, perhaps, the least pretension to pictorial or artistical effect of any kind, for they appear to have repudiated it altogether. In fact, we never before beheld any executed in such an exceedingly dry, little, and *niggling* manner: they have the look of being pencilled on china; nor are they one whit less singular for their colouring than for their drawing. Nevertheless they are so exceedingly small, that notwithstanding their singularity they are likely to escape notice altogether; for unless he consults his catalogue, a person would pass them by without at all suspecting them to be what they really are. Flatter they certainly do not; but we should hope both for the credit of Windsor Castle and Sir Jeffery himself, that they actually belie those parts of the building they pretend to show; else the style of the architecture must be as harsh, as bald, and as dry, as that of the drawings themselves. As to the other design, we can truly say we rejoice that it has never been executed, for however much it may have been "formerly approved," we do not think it would be at all approved now. To be sure, much cannot be made out; yet as far as we can make it out, it seems but one degree superior to carpenters' Gothic. Had these drawings not come from Sir Jeffery himself, we should say that he had been treated as unfairly as Mr. Barry has in No. 1117; but as it is, we hardly know what to think. We have however very strong misgivings; and only hope we may not discover that the architectural merits of Windsor Castle have been magnified exceedingly far beyond the truth; and that it is only in consequence of its being less accessible and less within the sphere of general observation that it has hitherto escaped the criticism which has treated many other buildings so very roughly.

We take the liberty of passing by Mr. Gandy's drawing (1165) merely remarking that if the page of letter-press attached to it in the catalogue does not sufficiently elucidate it, we cannot possibly attempt to explain in a paragraph what it would have taken us a day to study. The same remark will serve for his other drawing, 1172, a Design for the Ceiling of a Library; which is so far appropriate as it seems to be a very learned composition, but all its mystic erudition we apprehend, is sadly thrown away upon the visitors to the Exhibition.

Mr. Salvin's name excited expectations which are not fulfilled by No. 1171, "Scotney Castle, Kent, the Seat of Edward Hussey Esq. now erecting." It has far more the appearance of an old house, enlarged or altered, than of one entirely built from a design made purposely for it. What might be tolerated in the former case from necessity, becomes in the other positively offensive and defective. Neither does it present any individual features of sufficient beauty or value in themselves, to atone, as sometimes happens in such cases, for the mediocrity or worse than mediocrity of all the rest.

It is impossible to overlook No. 1177, "New County Courts, Worcester," C. Day, for it is one of the most strikingly and powerfully coloured drawings in the room. The design itself is good, as a mere copy of Greek, beyond which the architect has not at all taxed his invention,—for the façade consists only of an Ionic hexastyle portico, with one large doorway within it. This is certainly stealing brooms ready-made.

We thought we had dispatched all the "National Museum" designs in our last notice, but we now stumble upon another, 1177* by H. L. Elmes, "comprised within a space of two acres." It is not without merit in its composition, though rather extravagant and overdone; and we apprehend too that the idea of introducing a Grecian Doric structure over the centre of the principal mass, which is Corinthian, would be reprobated as an egregious solecism.

No. 1189 "Design for a Triumphal Monument," C. Viner, is so coloured that it looks as if it were intended to be constructed of ice; which would certainly be the most suitable—the only suitable—material for it, it being a "monstrosity" from which a thaw would relieve us. What triumph it may be intended to celebrate we know not—but most certainly it cannot be the triumph of art. However perhaps some confectioner may be smitten with it, and resolve to execute it if not in ice, in blanc manger.

After such an enormity, it is quite refreshing to look at something of the quality of 1193, "Design for a Baronet's Chapter or Club-house," H. Duesbury. But we are quite upset again when we turn our eyes to its neighbour 1194 "A National Repository of Arts and Sciences," J. Tarring, which is a farrago made up of the Dome of St. Peter's, and a huge mass of building; just as 1227 is of that of St. Paul's with an accumulation of piled up structures around it. This last, by-the-by, is another "National Museum," compared with which the British Museum becomes little more than a raree-show box.

For these dull extravagances we meet with some amends in No. 1195, "Original Design for Grosvenor Square Chapel, Manchester," H. Roberts. Whether by "Original Design" we are to understand that the building itself will be according to one which has been altered from this, we do not exactly know, but suspect such to be the case; and if so we are afraid that we cannot judge what the Church is to be, from what we here behold. The style is the earliest English or lancet Gothic, and in a far fuller and richer manner than is usual in any imitations of it. The composition is very pleasing and chaste,—broad, simple, and effective, free from any of that littleness and poverty which are the besetting sins of so many of our buildings. Below there are five doorways of lofty proportions, with deep splays decorated with shafts; and each doorway is surmounted by a gable or pediment. Three of them are in the centre compartment of the front, whose divisions are formed by rich buttresses terminating in polygonal pinnacles.

No. 1202, "Barcomb, South Devon, now building for N. H. Nugent Esq." E. Davis, is a strange medley of styles tastelessly jumbled together. If an architect is positively compelled to minister to the bad taste of his employer by perpetrating such things, he is in some respect to be pitied as well as censured,—that is, censured for not palming upon the other something like propriety, and imposing upon him something like good taste, while professing to accommodate himself entirely to his barbarous notions. If on the other hand, the offence be entirely his own, he ought to congratulate himself, that huge as is our statute book, it contains not one statute against such misdemeanor. It is indeed fortunate for many, that outrages of this kind, however gross and unpardonable, are not indictable.

No. 1208 "Sutton Hill, a house lately erected for Captain Richardson, in the Parish of Barcombe, Sussex, by W. Moseley," is a very different kind of design from the other Barcombe above mentioned. Though but a moderate-sized house, there is something bold and picturesque in the general composition, and some good detail. No. 1220 "Design for a Mansion," H. Smith, is likewise a very good subject of the same class. But "angels and ministers of grace defend us!" Why are our eyes to be afflicted with the vision of such things as No. 1214 "Design for a Union Workhouse," C. Eales. We grant that we do not expect any beauty in such a subject—res ornari negat. But then, in the name of common sense, wherefore should it be paraded before us in an exhibition, when the only excuse for introducing anything of the kind would be, for the purpose of showing how it could be rendered a picturesque if not a beautiful object?

No. 1226 "Church lately erected at Honiton," is one of the best designs, by Mr. Fowler, we recollect to have seen. It would be but a poor compliment to say the same of that (1245) erected at Goring, near Worthing in Sussex, by Mr. Decimus Burton. It is nevertheless a very good modern specimen of a village church, and beyond all comparison better than many of the churches lately erected about town.

Why such a drawing as No. 1237 "Elevation and Section of the Tower and Spire of St. Vedast," should be hung up, unless to cover so much wall that would otherwise have been left bare, we cannot conceive. Mr. C. Davy, whose name shows itself so conspicuously on the frame, has no more claim to the merit of it,—if merit there be any in it,—than has the compositor to this article of ours;—which we here bring to a close.

IRISH RAILWAYS.

(From a Correspondent.)

The following is a list of Irish railways, perhaps more detailed and exact than any that has yet appeared. It is furnished with a view of reconciling what might otherwise appear to be a contradiction in the subject matter of two communications regarding Irish railways in your journals of June and July. In the list of Irish railways published in that for June 1838 (p. 234), it was not intended to give any account of what lines of railway the Irish Commissioners had surveyed through Ireland, or indeed anything connected with their operations; because nothing has yet been publicly made known regarding the labours of that Commission. Such being the case, any communication made on that subject being unofficial and unauthorised, or at least bearing no record of any authenticity of that kind, can only be received by the public at present as purely conjectural. But on the other hand, if your second correspondent be officially connected with the Irish Railway Commissioners, a list of the railways proposed by them through Ireland, the direction and length of each line, gradients, probable expense of construction, and probable amount of revenue &c. &c., would be very interesting to the public. If at the same time, he could give a statement of the circumstances which have induced the great delay that has occurred in the presentation of the report itself to parliament, and point out the modifications which are understood to have been introduced more than once into some of the principal lines, he would deserve the thanks of the Irish public.

The account of the Irish railways contained in your journal for July 1838 (p. 264), whether as regards the proceedings of the respective companies, or even perhaps those of the Irish Railway Commission, must be viewed by those acquainted with the subject as extremely defective; but it is to be hoped that your correspondent will be able to give to the public in your next number, something that will remove the grounds of complaint against the list he has already given.

DUBLIN AND KINGSTOWN RAILWAY.

This railway was originally designed and laid out by the late talented engineer Alexander Nimmo Esq., who died while the bill for it was being carried through parliament; Mr. Vignolles then became the engineer.

WATERFORD AND LIMERICK RAILWAY.

This railway was first surveyed by Elmes and Hollingworth, Architects and Surveyors, who were paid six or seven hundred pounds for their surveys of the line: afterwards Mr. Nimmo was employed to survey and report on it; his survey was lithographed and his report printed. The report is a most interesting document; and to those who are capable of appreciating its merits, the information it contains, and descriptive style of language, unfold the highly gifted powers of its author. An act was obtained for this railway, but it has expired. Mr. Thomas Telford, examined that part of Ireland and reported on this railway favourably. The country was also examined and the railway reported on, by Mr. George Stephenson.

And again by order of the Board of Public Works in Ireland, this project was examined by Mr. Bald; and on his report an offer was made to the company by government of a loan of one hundred thousand pounds sterling, provided that a subscription to that amount could be obtained to carry it on. This was not accomplished, and accordingly the government did not advance their loan.

In the autumn of 1836, a new Company was formed with a most influential committee, on which by vote of the board, the chairman and two directors of the Great Western Railway accepted seats. The object of this company is to effect a new survey and obtain a new bill in parliament; these proceedings are only suspended out of respect to the Irish Railway Commissioners; they have nominated, I. K. Brunel F.R.S. &c., Consulting Engineer;—and William Bald F.R.S.E. &c., Directing Engineer.

RAILWAY FROM CAVE-HILL TO BELFAST HARBOUR.

An act has been obtained for this Railway; the works are progressing, but some difficulty exists in fixing on the terminus at Belfast Harbour, which cannot be decided on until some of the various plans of improvement for that port are adopted. By order of the Board of Works in Ireland, Mr. Bald examined and reported on this railway; and a considerable sum is ready to be advanced by loan towards its completion when application is made and security given. This railway is for the purpose of carrying limestone down from Cave-hill to Belfast harbour for export, and it is considered by every person that when finished it will be one of the most useful railways yet planned in Ireland.

RAILWAY FROM DUNDALK TO CAVAN.

An act has been obtained for this railway; Mr. M'Neil Engineer.

RAILWAY FROM DUBLIN TO GALWAY.

The line of this railway was traced out by Mr. Bald and Mr. Henry, and a minute survey has been made of the Western branch from Athlone to Galway by the latter. No act has yet been obtained for it, but the plans are before the Irish Railway Commissioners; and a London board composed of eminent bankers, merchants, and Irish landowners is ready to proceed with the project.

DUBLIN TO DROGHEDA.

An act has been obtained for this railway;—Engineer William Cubitt Esq., F.R.S. M.R.I.A. &c.

ULSTER RAILWAY, BELFAST TO ARMAGH.

This railway was designed, surveyed, and levelled, under the direction of Mr. Bald and Mr. Woodhouse, and an act obtained for it;—Consulting Engineer, Mr. George Stephenson.

RAILWAY FROM DUBLIN TO MULLINGAR.

This railway has been surveyed and levelled under the skilful superintendence of Mr. Alexander Nimmo, nephew of the late eminent engineer of that name, and a report written by him has been printed, but no act has yet been obtained;—Engineer, Mr. Charles Vignolles.

RAILWAY FROM DUBLIN TO KILKENNY.

An act has been obtained for this railway; but by a clause in the act, its construction has been restricted for one twelve month, beyond a distance of seventeen miles from Dublin. The effect of this restriction has been to prevent anything whatever being done, up to the present moment;—Engineers, John M'Neil and David Aher, Esqrs.

RAILWAY FROM DUBLIN TO LIMERICK.

This proposed railway has been surveyed and levelled under the direction of Mr. Bald the engineer, by order of a most respectable board of London directors, elected at the instance of the Chamber of Commerce and principal merchants of Limerick, for the purpose of carrying this undertaking into execution.

RAILWAY FROM CORK TO COVE.

An act has been obtained for this railway;—Mr. Vignolles, Engineer.

RAILWAY FROM BELFAST TO HOLLYWOOD.

This railway will embank in from the sea more than 1200 acres of rich sea land; no act has yet been obtained;—Mr. Bald, Engineer.

RAILWAY FROM DUBLIN TO ARMAGH;—INLAND LINE.

This line of railway was first surveyed and levelled under the direction of John Urpeth Rastrick Esq. Engineer; and it was again traced and surveyed under the direction of Mr. Bald. The plans, maps, and sections, have been all finished, but no act has yet been obtained;—John Urpeth Rastrick Esq. Consulting Engineer; — William Bald Esq. Directing Engineer.

RAILWAY FROM DUBLIN TO ARMAGH;—BY THE SEA COAST.

This railway was surveyed and plans made; but no act has yet been obtained;—William Cubitt Esq. Consulting Engineer;—John M'Neil Esq. Directing Engineer.

RAILWAY FROM BELFAST TO CARRICKFERGUS.

This line of railway was traced out by Mr. Bald; the whole length is one continuous level, and it was calculated to embank in from the sea 1500 acres of rich sea land.

By order of the respective companies, copies of the surveys for the following lines of railway were delivered into the office of the Irish Railway Commissioners in the autumn of 1836, viz.,

Dublin to Limerick.
Dublin to Kilkenny.
Dublin to Armagh.
Belfast to Hollywood.
Limerick to Waterford, &c. &c. &c.

P.S. It has just been announced that the Irish Railway Commission are about presenting their report to parliament; and on reading over the extracts taken from it and published in the Sun of Friday, July 20, we believe that the intention of the government in issuing a royal commission to lay out a system of railways through Ireland has been of the most laudable and praiseworthy kind; but whether the commission will confer the benefits contemplated or not, time only can unfold. Without reading over the whole of the report, it would not be fair to enter on a discussion of any of the very many points which are even put forth in the extracts contained in the Sun newspaper above alluded to; but it may be observed that the system of railways laid out by the Railway Commission in the South of Ireland, is at variance with all the lines proposed by the respective companies in that great district. Looking at the composition of the royal commission, their practical skill, their experience in railway engineering, and power to decide on matters of so serious and so professional an import, where many millions sterling are perhaps to be expended, the legislature will no doubt avail themselves of the highest practical skill and talent that the empire can afford, to examine and decide on what may be considered in their opinion the best lines of railway for Ireland. Reason and good sense ought to impress this on the attention of the executive, as the only safe mode of proceeding, where so much difference of opinion exists, and where so much capital is to be expended. It ought to be borne in mind, that the railways projected for the South of Ireland, and to which independent companies had offered to devote their capital, had previously been reported on by the most eminent practical engineers that the empire has produced; we need only mention Nimmo, Telford, and Stephenson, to convince the reader of the truth of this statement. The most serious consideration will therefore be required before the suggestions of this commission are adopted, to the prejudice and suppression of the views of such men as those we have named. There is another proposition contained in this report, which will doubtless prompt still more serious reflections. The commissioners—after regretting that England should be the only country in which the construction of railways was left to the independent enterprise of private companies, and pointing out that the less perfect system of government in America did not admit of a better arrangement in that country, and stating that in France a more powerful government had taken the prosecution of such works into its own hands—call upon the British government to subject all the railways in Ireland to one body of capitalists, whose proceedings are to be under the management and control of Ministers.

THE THAMES TUNNEL WORKS.

RETURN TO AN ORDER OF THE HON. THE HOUSE OF COMMONS, DATED JUNE 27, 1838, FOR COPY OF MR. WALKER'S REPORT TO THE TREASURY ON THE WORKS AT THE THAMES TUNNEL.

I duly received a letter from Mr. Baring, under date the 7th of October, 1837, informing me "that the Lords Commissioners of her Majesty's Treasury had under their consideration a report from the clerk of the Thames Tunnel Company of the 13th September, with an account of the breaking in of the river on the 23rd of August, 1837, and various papers relating thereto, which, with the former report from the same party, and special reports from Mr. Brunel of the works proposed to be carried on at the Tunnel, were referred to me for my consideration and report, previous to their Lordships giving any direction on the application for consent to the several propositions made by the engineer and directors of the Company for continuing and facilitating the progress of the works."

I gave the subjects my immediate attention, and was preparing a report thereon, when on the 2nd of November another (the fourth) irruption of the Thames took place, and on the 6th, when I visited the works of the Tunnel, Mr. Brunel, the engineer, and Mr. Charlier, the secretary, requested a postponement of my report for a short time, until they should complete an expected arrangement with the navigation committee of the river Thames, from which they expected increased facility and security. This request I communicated to Mr. Baring by letter on the 9th of November.

I have since seen Mr. Spearman's letter of the 2nd of December, transmitting to me, by command of the Lords of the Treasury, a copy of a letter from the secretary to the Thames Tunnel Company, dated 15th November, together with a report of Mr. Brunel on the present state of the Tunnel, and the best mode of proceeding, and also a plan of the works, with a request that I would communicate to their Lordships my opinion upon the several points referred to in the papers, previous to their determining on the proposals and recommendations of the company.

Since receiving the above instructions, Mr. Spearman has stated to me the desire to be, that every point, particularly as respects cost or estimate, which I consider of importance in the general question of the Tunnel, should be included in my report, so as to bring the whole fairly under the consideration of their Lordships.

That Mr. Brunel's different reports, in which the same recommendations are repeated, may be brought to their Lordships' recollection, I shall give a short abstract of the main points in the order of date.

In his report of May 2, 1837, Mr. Brunel ascribes the difficulties which had retarded the progress of the Tunnel for the last five months to the excessive rains of the preceding autumn liquifying the ground between the ceiling of the shield and the river, and causing it to run into the works; he states that this has been augmented by his being deprived of the pumping well and drain from Wapping, which is stated to have been originally intended, and to have been considered the most efficient means of drainage, particularly as the dip of the strata is to that side, and that before any satisfactory progress can be calculated on, the proposed pumping-well, with a drain or drift-way, should be made, but that a preferable plan would be to sink the 50 feet shaft for the foot passengers' descent, which would, he considers, be a better means of drainage, and would give employment to the workmen when not in the shield. The fact of the pumping at the entrance of the London Docks having dried the wells in that neighbourhood, is adduced as a proof that a pumping-engine on the Middlesex side would diminish the land-springs in the Tunnel.

Mr. Brunel estimates the expense of the shaft, including the steam-engine, pumps, &c., at 6,814*l*., and the pumping-well alone at 2,990*l*., independent of the drift-way or drain, which he calculates at 4,310*l*., making together 7,000*l*., which sum he presumes would be saved by forming the shaft rather than the well at the present time, exclusive of keeping the workmen and establishment employed, and thereby reducing the amount which is now charged to the tunnel account. He also mentions the impregnation of the water with sulphurated hydrogen, which has proved very injurious to the health of the workmen, as another reason for making the drift-way, as it would be the most effectual means of drawing it off. The report states, that "the fact of 16 feet of the Tunnel having been completed under the described difficulties, is a proof that it can be accomplished, though, owing to the disadvantages, at an enormous price, and that it never could be intended in the conditions of the Treasury that he should be deprived of the means of completing the work at the estimated cost."

Mr. Brunel's report, dated 9th of August, 1837, recapitulates the substance of his previous report, and adduces the successful result of pumping-engines and drift-ways erected for the purpose of taking off the land-springs that impeded the formation of the Kilsby tunnel, in the line of the Birmingham railway, as a proof of the good effect that would be felt in the works of the Thames Tunnel, by a pumping-engine on the Middlesex side. He states also, as an argument for the works he proposed in his former report, the importance of giving the disturbed and artificial ground time to consolidate; and now proposes, on the completion of the Middlesex shaft, to commence the tunnel on that side also, with a view to greater expedition and economy, and to keep the full complement of men more regularly employed by having the two ends to work at. This, it is stated, would reduce the cost of conveying the men, materials, and excavation to the shaft on the Surrey side. In this report Mr. Brunel further states, that so soon as the plan he has proposed is in satisfactory operation, the formation of the carriage-roads might be commenced simultaneously with the tunnel; and that by the various means he now proposes, a saving might be effected in the time of four and a half years,

which in my report of April, 1837, I considered requisite for the completion of the tunnel and approaches, and that consequently there would be an earlier receipt of toll, and a saving of current expenses and machinery to the amount of 15,000*l.*, by the works being completed one year and a quarter within the time I had calculated. Various accounts and calculations in proof of his several positions are appended to this report of Mr. Brunel, and an estimate that to carry on the works as he recommends, the sum of 94,000*l.* will be required during one year from August, 1837.

The Lords Commissioners of her Majesty's Treasury having refused their assent to the tunnel being begun on the Middlesex side, Mr. Brunel, in his report, dated the 7th of September, 1837, repeats the other recommendations of his former reports.

The last report of Mr. Brunel that is referred to me, is dated the 15th of November, 1837, the fourth irruption of the Thames having taken place on the 2nd of that month. In this report, he considers the third irruption (that of the 23rd of August) as not having been unfavourable in one point of view, as it would enable substantial ground to be substituted for the loose silt that had been worked into the tunnel by the irruption; in proof of which he states that the work done before the third irruption cost 900*l.* per lineal foot, while what was done between the third and fourth irruptions cost only 630*l.* The former recommendations and arguments are repeated, and in addition it is now stated that the fourth, or last irruption, was caused in a great degree by the part of the tunnel then in progress being under the portion of the river chiefly used for navigation, and that the depth being small, the artificial bed of the river, or roof of the tunnel, was liable to be disturbed by passing vessels. This Mr. Brunel now proposes to remedy by deepening a part of the river where the tunnel is formed, moving some of the ships in the tiers near the tunnel from the northern to the southern side of the river, according to a plan which accompanies his report, throwing the space which is required to be kept clear for the navigation, from the north side towards the middle of the river over where the tunnel is formed, so as to leave the space which is in advance of the works free for tunnelling operations; and then substituting a thicker roof of clay and gravel raised above the present level, to which, from the navigation not being then over that part, there would not be the same objection as at present. This thicker roof Mr. Brunel proposes to make 100 feet in length, or in advance of the shield, and 100 feet on each side of it. He calculates on a great saving in the end from this artificial covering, which he estimates at 1,800*l.*, and ascribes much of the late trouble and expense to the passing ships, and the want of a sufficient thickness in his roof, which the navigation prevented his having.

The reports are drawn up in great detail, and the above abstract is to be considered not as a substitute for them, but only as bringing the leading points to recollection in one view, without the repetitions which the reports themselves, being of different dates, naturally contain.

It is now my duty to state my opinion, which is, to recommend Mr. Brunel's proposals to be adopted as the most economical and creditable way of executing the works, if it be the determination that the Thames Tunnel (a work which for many years has attracted much of the public attention in this, and still more in other countries, and upon which upwards of 80,000*l.* of public money has been advanced) shall be completed, without making cost an element in the question. I would then even advise more effectual works in front of the shield than Mr. Brunel's description and estimate of 1,800*l.* contemplates; for if the work is to be considered a national or government work, a repetition of the danger, the late irruptions, and the enormous expense of the work, would be discreditable, and as it may be, it ought to be prevented. In addition to Mr. Brunel's proposals, I would recommend, after the removal of the clay that has lately been thrown in, and a portion of the silt, that two rows of close whole timber piles should be driven between where the ground begins to rise and the present shield, one row on each side of the line of the tunnel, with space between sufficient for the shield to travel, and to as great a depth as they can conveniently be driven, the heads being level with low water. These, with a return of shorter piles at the end, would form a dam against the silt. The piles being driven, I would continue the dredging of the silt in the space enclosed by the piles, and then fill up with clay, gravel, &c., as at present, to a sufficient height, and afterwards give the mass time for consolidation before attempting to advance the shield, which in my report to the Commissioners for the loan of Exchequer Bills, I stated to be an essential element for success in the undertaking. In the progress he has made through very bad strata, Mr. Brunel has fully tried and proved the great power of his excellent shield; but the strata, rendered worse by the irruptions and the causes assigned by Mr. Brunel, are now too bad for even the shield to overcome. By the substitution of good artificial soil to work through, and keeping the silt or sand back by the piles, there would be much less difficulty or danger; and with proper precautions, my decided opinion is, that the tunnel may be completed notwithstanding the late irruptions, and with comparatively little difficulty or risk.

Here the question naturally presents itself, at what cost? and to answer it it with the probability of accuracy is still very difficult.

The amount of the company's capital expended previous to any advance of public money was 180,000*l.* On the 27th of February, 1837, when 64,600*l.* received from the Commissioners for the Loan of Exchequer-bills had been expended, I estimated the	64,600
addition then required to complete it, at - - - - - -	310,600
Making, exclusive of the company's capital - - - -	£374,000

Between the 27th of February and the 2nd of November, 19,300*l.* have been expended, making 83,900*l.* of public money expended to the 2nd of November, but the quantity of work done with the above 19,300*l.* is only 19 feet six inches, making (inclusive of 1,400*l.* for pumping, excavating, and claying, after the third irruption) nearly 1,000*l.* per foot, which very much exceeds all previous estimates, and proves what I stated in evidence before the Select Committee of the House of Commons, that no prudent man would commit himself to the accuracy of an estimate of this work, while it shows also the impolicy of attempting to drive on the shield through the present bad soil without a sufficient covering and time for consolidation.

In the present situation, I consider that the sum of 150,000*l.* should be taken as the estimate for completing the tunnelling; and that the shafts and other works remaining to be done, together with the purchases, should not be estimated under 200,000*l.*, making, with the 84,000*l.* of public money already expended, and the company's capital previously expended, a total of 614,000*l.* for the estimate of the work, or upwards of triple the original estimate, and this is allowing but a moderate sum for contingencies, which have heretofore been very heavy.

I have estimated the great descents at double Mr. Brunel's estimate, and yet, from the nature of the work, I have as much doubt as to the sufficiency of that sum as of any other item in my estimate.

If, however, in place of determining to complete the tunnel without reference to cost, which the foregoing observations suppose, the Lords of the Treasury resolve, as heretofore, to confine their operations to the advance of the tunnel, so as to remove any doubt of its getting through, before they sanction a further heavy outlay, then although I agree with Mr. Brunel that the pumping-well or the shaft with the drift-way or drain would lessen the springs, I do not by any means think them so essential to the progress of the work as to agree in recommending their being proceeded in at present. Up to the time of the second irruption, in January, 1828, the works were under the uncontrolled management of the directors and engineers, and during that period nothing had been done on the Middlesex side with a view of draining the water from the tunnelling, although it had been advanced to the middle of the river, only 155 feet having been done since; but in the report of 1831 the drift-way or adit is proposed and estimated, with the pumping-well, at 6,000*l.* Mr. Brunel informs me that the drainage in the tunnel is now very small, and the short time in which the water, after irruptions, has been taken out, proves that the present pumping-engine is fully equal to the work.

More rain by two inches fell during the last six months of 1836 than of 1835,* an increase, but not such as to cause a very important difference in the workings, which I ascribe almost entirely to the ground towards the Middlesex side being of a looser and more sandy and silty nature than towards the south side; this, it has always been said by the Trinity officers and others acquainted with that part of the river, would be found to be the case; so that, although the spring-water has been an evil and an hindrance, the Thames water has been another and probably a greater, and is the present enemy, which makes the cases of the London Dock or the Kilsby Tunnel parallel to a certain extent only. It is not in preventing the communication with the spring, but with the river water, that the artificial roof of clay, &c., has been useful.

I agree that the air for respiration would be improved by the drift-way, and probably the present air-pump, which is worked by the steam-engine, rendered unnecessary; but this pump, ingenious as all Mr. Brunel's applications are, appears completely to answer the purpose, and would probably be found quite as effectual in abstracting the sulphurated hydrogen as a drift-way at the bottom would be.

I cannot agree as to the saving of expense by the shorter distance to the Middlesex shaft; the difference of distance in the present situation of the shield would be only 70 yards, and as an excellent railway is laid, and machinery attached for working it by the steam-engine, I am sure that the conveyance of the excavated soil along the bottom of the tunnel to the low ground on the Surrey side must be at least as cheap as to the Middlesex side, where the ground is chiefly covered with buildings, and does not require to be raised; and that, as a passage to and from their work, the workmen would generally prefer the spacious lighted tunnel to a drift-way until the difference of distance is much greater than at present.

That the well or shaft on the Middlesex side would give employment to the miners and other workmen when they cannot be employed in the shield, and thus lessen the amount now charged to the tunnel, I entirely agree; but my opinion at the same time is that they may be fully employed in securing the ground in advance of the shield, according to Mr. Brunel's plan, or with the additional piling, such as I have suggested. It appears to me that sinking the shaft, driving a drift-way, making a new shield, and proceeding from the Middlesex side, would amount to a committal to go through with the undertaking, and ought not to be begun until that, as a previous question, has been determined.

In stating this, I am in some measure influenced by the opinion that Mr. Brunel's estimate for the works on the Middlesex side is too low. He estimates the pumping-well and drift-way at 7,000*l.*, and the shaft-engine and pumps at 6,844*l.*, and gives a decided preference to the shaft. Now, the shaft on the Surrey side is stated in the account to have cost 20,000*l.*, and evidently the drift-way, 4,310*l.*, should have been added to the shaft as to the well plan. The Middlesex shaft may, and probably will, be less expensive than the Surrey one was; I think it unsafe to trust calculation against experience, so far as to take one-third of the actual cost of the Surrey, as the estimate for the Middlesex shaft.

Of the propriety and importance of changing the channel for the passage

* The quantity of rain that fell in the last six months of 1835 (as kept at the Royal Society's Rooms) was 10½ inches, and in the corresponding period of 1836 it was 12½ inches. In the same period of 1834, a very dry year, it was only six inches.

of vessels, from the part of the river in front of the shield which has yet to be tunnelled through, over to the part which is tunnelled, and forming a body of compact gravel and clay in front of the shield, in the way Mr. Brunel proposes, to a greater thickness than is now compatible with navigation, there can be no question; and I am glad to learn, by a letter received from Mr. Charlier, that the Navigation Committee have agreed to the proposal; and as Mr. Brunel considers that this will remove much of the cause of the late irruption, by enabling him to have a better covering of clay, and preventing vessels grounding upon the artificial bed, and estimates the necessary work at only 1,800*l*., I have no hesitation in recommending to the Lords of the Treasury to sanction it, even with the addition I have proposed, should Mr. Brunel be disposed to adopt it. I think the expense of the piling and clay may be taken at about 10,000*l*., and I feel assured that, if the completing of the tunnelling be the object, this outlay will be more effectual, and much less in amount, than proceeding with the works on the Middlesex side; from the length of the river proposed to be covered with clay, if done according to Mr. Brunel's plan, being three times greater than with piling suggested by me, I think the difference of expense of the two plans would be small.

Having now given my opinion on the various points that have been referred to me, I would beg to add, that as the Thames Tunnel is Mr. Brunel's work as respects design and responsibility, any measure that may be proposed for executing the work should, in my judgment, have his approval. If that approval is refused, unless the Lords of the Treasury will consent to works which exceed the amount they have yet thought proper to agree to, almost any course would be better than letting the complaint be repeated, "that the engineer has been deprived of the proper means of completing the work at the estimated cost."

December, 1837. JAMES WALKER.

FRESCO PAINTING.

Our attention has been called to a very interesting course of lectures on fresco painting, by Mr. E. H. Latilla, now being delivered at the rooms of the Society for promoting Practical Design, Leicester Square. The object of this institution is to extend the application of the Fine Arts to the practical purposes of ordinary life; and there is no one object which is more worthy of this attention than internal decoration. It is indeed highly to be regretted that in a country which possesses so many fine works, architecture should be shorn of half its attractions. In most other countries, cathedrals and palaces shine with all the attractions of statues, and all the varieties of colour. Abroad, the architect may justly be proud of a profession which is considered worthy of the strongest support of all the sister arts. In Italy, the architect acquires the greater glory, by the powerful assistance of the sculptor and the painter. In the golden age of the arts, the proudest monuments of architecture were not considered finished till they were enriched with the works of Michael Angelo, Raffaelle, or Titian. Thus the finest productions of the great masters are known by their locality; they are not distinguished simply by their own titles, but as being in such an edifice. Artists laboured with the greater success, when they were animated by the consideration that their productions were not to be sent as beggars to seek their fortunes singly in the world, but that they had the power of erecting a large monument to their fame, and were assured of all the advantages of a noble edifice. It was this feeling that produced the Sistine Chapel and the Vatican; —and what have we in England to compare with these?

Now when a large public building is in contemplation, it is unfortunately too often the case that it is considered as a mere affair of stones—bricks and mortar—very little sculpture is thought of, and both fresco and oil painting totally neglected. The effect of this, is the production of a large raw mass to be smoked into softness; we go into a palace as into a desert, and into a church as into a cave of the sea; finding nothing to relieve the monotony of the walls, if the decoration that may be attempted do not increase it. This is disgraceful to us who have one of the finest schools of architecture in Europe, if not the best; while the French, and still more the Germans, are paying the greatest attention to this essential department. The King of Bavaria, especially in the Pinacotheca and Glyptotheca at Munich, has produced some of the noblest specimens of modern times. Those museums, decorated with appropriate paintings and emblems elucidatory of their objects, are undoubtedly the finest in Europe. There no one can mistake the character and designation of the edifice; for the moment that it is entered, every wall tells its story in the most natural language,—that of the descriptive arts. In England, on the contrary, whether you go into a palace, a senate-house, or a gaol, the same unmeaning nakedness leaves the visitor often uncertain which edifice he has entered. In Italy, neither palace nor church is left unadorned; every wall speaks to the eye equally with the whole building; and even down to the commonest houses, there are few which are not decorated in some manner more artistical than the nondescript paper hangings with which we supply their place.

Painting is such a general accompaniment of architecture, that it is indeed truly singular that ours should be the only school which has omitted its employment. It has been adopted by every style and every age; and its neglect has been reserved only for this country and the present day. The paintings in the temples and tombs of Egypt, remain to this day to show how that people could appreciate their advantage; they were aware how far this art could strengthen the character of an edifice and augment its impression. No people ever attained a better conception of what was solemn in architecture; and none, except the Gothic nations, availed themselves so much of its power on the minds of the multitude. In maintaining the impressiveness of a building, they never omitted the assistance to be derived from its decorations; and this union of all the powers of art must have rendered an Egyptian temple in perfection, a speaking monument to the multitudes who crowded to its worship. The grandeur of the edifice, the mysterious and gigantic forms of the colossal gods, and the variety of the colours dispersed every where, must have increased in effect from the subjects of the paintings. These frequently represented the simplest occupations of the peasant, and similar subjects with which the mass of the people could readily sympathise; from these objects the mind was rendered more susceptible of the grandeur of the scene around, and was softened by degrees to the impressions of awe and mystery, which were the characteristics of their worship. The numerous instances in which painting was recognised by the Greeks and Romans as an important adjunct in architecture, are too trite to allow of repetition. In the Baths of Titus, these latter left a torch to re-kindle the altar of art, for it is to them that we mainly owe the Loggie of Raffaelle, and the Mantuan works of Giulio Romano. In the Italian school down to the present day, this union has never ceased. In the Moresque and all the Oriental, their mastery in this department has been complete; and they have by their admirable combinations of colour, produced that effect, of which by their religious scruples they were deprived, in the representation of the human form.

It is only at the present day in England, that this neglect has taken place; for from the earliest times, we possess testimonials of the manner in which our ancestors esteemed the union of painting and architecture. In the Saxon periods there are repeated records, and in the later styles we possess abundant existing evidence. It is the Gothic architects who have most availed themselves of an important and peculiar feature in their styles, the use of painted windows; while in Winchester Cathedral and many other buildings, we find the roofs painted, the walls covered with frescos, and even the very pavements decorated. It is unfortunate that this is not continued in the present edifices of those styles; for surely where religious scruples have been overcome as to coloured windows, none can exist with regard to painted ceilings. At a later period, the genius of Rubens was employed to decorate Whitehall Chapel with some of his finest works; as still later, Thornhill painted the dome of St. Paul's.

Were this union of all the arts attended to in architecture, it would undoubtedly tend to elevate the character of the profession. Every architect should possess some acquaintance with the other departments of the arts; and such knowledge could not fail to refine the mind, and direct the taste towards harmony and beauty. We have possessed men who have fully appreciated this; and in Sir John Soane's Museum we see an eminent instance, in the manner in which he recognised the mutual connexion of all departments of the arts.

There is now a better spirit abroad with respect to the arts; and the interest which they at present excite from patrons and connoisseurs, imperatively requires of the professional man an equal degree of attention. It is a great proof of sounder taste, that the vitiated styles of Louis Quatorze and Quinze are now on their decline; and we fully expect that the style of the *Renaissance* which is already fully established in France, will soon be in equal vigour here. Not that we consider the style of the *Renaissance* to be either pure or good *per se*,—but still, a style which exercised greater and earlier genius than that of the declining period of Louis Quatorze, must be hailed as an advance made in the career of the arts. There is no period which could be more auspicious than the present for the execution of works in fresco, as we now possess advantages which were denied to the artists of the fifteenth century. In the remains of Pompeii, and in the discoveries of three centuries, but particularly in those of the purest Greek works, we possess materials for study which were denied to Raphael and Paul Veronese, who had only the Baths of Titus; while we have not only all the assistance to be derived from these latter specimens, but in addition, the labours of the great masters who have studied from them.

We recommend those who feel interested in this subject to hear the rest of the course of lectures which are given by Mr. Latilla, an artist who has paid particular attention to this subject; and who in his efforts to extend it in this country, has been gratified by the patronage of the nobility, in many works which do equal honour to his skill and to their taste. At his first lecture among many other highly interesting illustrations, he exhibited some original specimens by Paul Veronese.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

REPORT OF PAPERS READ AND PROCEEDINGS, SESSION 1838.

(*Continued from page 259.*)

On the Limestone, the Lime Cement, and method of Blasting, in the neighbourhood of Plymouth. By W. Stuart, M. Inst. C. E.

Plymouth abounds in limestone, which may be raised in solid masses of from three to ten tons; it is used most extensively for building and for lime manure. About 13 cubic feet weigh a ton; the limestone is of a light blue or grey colour, in general free from metallic veins, but with some indications of manganese and iron-stone, round pieces of the latter being found in clay beds, intermixed with the rock, and a vein of ironstone four inches thick at the surface of the rock, and dipping towards the south, has been opened.

The author then proceeds to describe the general method of making cement in that neighbourhood, and the method which he has employed with considerable advantage.

The bit or iron rod, called a jumper, is generally used. In pitching a deep hole, a 2-inch bit is used for about four feet, and a 1¾ inch for the next four feet, by one man; then two men are employed with 1¾ inch to the depth of 14 feet, and 1½ inch to the depth of 21 feet. A constant supply of water is required during boring the hole. The hole being well dried, about one-third is filled with powder, say 15lb.; a needle is introduced as far as possible without driving it; the hole is tamped with dry clay to the top, and then covered with a little wet clay, to prevent any of the loose particles falling in when the needle is withdrawn. A reed, filled with powder and split at the top, to prevent its falling to the bottom of the hole, is inserted, and a stone laid upon it; the powder being ignited by a piece of touch-paper and a train, the reed flies to the bottom of the hole, and ignites the main load. The rock is generally cracked and loosened to a considerable extent, if not thrown; in that case, the needle is driven through the tamping, and such a fresh charge is run through the needle-hole as may be requisite. From six to eight tons of rock are generally blasted with one cwt. of gunpowder. The paper is accompanied with drawings of the jumpers, the tamping bar, the needle, and the discharging reed.

Account of the Pont-Y-Tu Prydd, over the Taáf, Glamorganshire. By Thomas M. Smith.

In 1746, William Edwards undertook to build a bridge over the Taáf; the first, which consisted of three arches, was carried away by a flood; the second, of the same dimensions as the present, fell from the too great load on the haunches. Before commencing the work again, Edwards is said to have consulted Smeaton; and either from the advice of that distinguished man, or from his own experience, he left in each of the haunches three cylindrical openings, from face to face, and it is said that the intermediate spaces are filled up with charcoal. The bridge was finished in 1750. The arch measures 140 feet betwixt the abutments, and has a curved line of 35 feet. The width of the soffit is 15 feet 10 inches at the springing, and 11 feet 5 inches at the crown; the width of the roadway at the crown being 11 feet.

The preceding is accompanied with a beautiful drawing, exhibiting the elevation, plan, and section, of the bridge.

On some Operations in Blasting in the Jumna, and at Delhi. By George Tremenheere, Lieut. Bengal Engineers, Assoc. Inst. C.E.

In this paper, the author gives an account of the charges of powder, and the mode of tamping in blasting under his direction, during the years 1828 and 1829, for improving the navigation of the Jumna, and from the years 1831 to 1835, at the fortifications of Delhi. The jumpers were 6 feet long, and 2½ inches in diameter; the blasts 5 feet deep, and at a distance of 4 feet from each other. The rate of boring varied from 2½ to 5 feet per day's work for two men. A double-headed jumper was used, to render the hole completely circular for the reception of the canister, about 2½ feet in length and 2 inches in diameter, and filled two thirds with powder and the rest with sand. The small tube reaching to the surface of the water contained quick-match, with a piece of slow match at the extremity. The canister, well greased, was placed in the hole without any additional tamping. The method of removing the masses, and the tools employed, are described and explained by drawings.

At Delhi, the blasting was in dry rock, and economy of gunpowder being of more importance than economy of time, tamping was resorted to. For this a stiff red clay, slightly moistened, was employed, and the tamping-bar was of wood, and the priming wire of copper. Any dampness which might exist in the bore was obviated by a tube of coarse paper, greased on the outside. Fine mealed powder was used as priming, and a piece of port fire for ignition. If the firing did not succeed, a fresh priming hole was bored in the tamping; or the mine abandoned. In large irregular masses of rock, the depth of the bore, or the intervals between the blasts, will generally represent the line of least resistance; and the following results were obtained in the rock at Delhi, which is hard quartz.

The line of least resistance not exceeding one foot, a charge of 2 oz. is sufficient; the line not exceeding 4 feet, and the rock not being highly crystaline, 3 oz. per foot will be sufficient.

The charges will vary with the tenacity of the rock, but the following may be a general guide:—the line of least resistance being 1, 2, 3, 4, 5, 6 feet, the charge will be 4, 8, 14, 20, 26, 36 ounces.

On comparing the charges used at Delhi, where stiff clay was used as tamping, with those in the Jumna where sand was used, the following table is the result:—

Line of least resistance.	With clay tamping.	With sand.
2 feet	8 oz.	26·8 oz.
2½	10	33·5
3	12	40·2
4	20	53·6

The charges in the last column are to those in the second as 3 to 1, nearly; they are not, however, given as the least required, but are those actually used.

The author is of opinion, that nowithstanding the increased expenditure of gunpowder when sand is used as a substitute for tamping, the saving of time and labour is such as may, under some circumstances, counterbalance that disadvantage. This is stated to have occurred on the Jumna, where, owing to the rise of the river during the periodical rains, it was required to execute the greatest possible quantity of work with large bodies of men in a given time.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

At an Ordinary General Meeting of the Members, held on Wednesday the 23rd of July, 1838,

EARL DE GREY, President, *in the Chair,*

Letters were read from Chevalier Gasse of Naples, and Signor Ittar of Catania, Honorary and Corresponding Members.

The following donations were received:—J. G. Wilkinson, Honorary Member; copy of his work on the manners and customs of the ancient Egyptians, 3 vols. 8vo.—H. E. Kendall, Fellow; Designs of Inigo Jones, folio; Swan's designs, folio; Pozzo's Perspective, 2 vols.; Vedute di Livorno; Murphy's Travels in Portugal; Daviler's Architecture, 2 vols.; Danish Vitruvius, 2 vols.; Halfpenny's Architecture, 1 vol.; Arch of Septimus Severus, folio; Description de l'Hostel des Invalides, folio; Views of public buildings in Paris.—Baron Wettenstedt; L'Antichita di Roma di a Fulvio, 12mo.—J. H. Taylor, Fellow; Lithographed plan of the Westminster Improvements, as prepared by Messrs. Bardwell and Taylor.—G. B. Webb, Associate; Print of Arc de Triomphe de l'Etoile.—C. J. Richardson, Fellow; 1 vol. of private plates of the late Sir John Soane.—J. Blore, Associate; copy of his Lectures on Gothic Architecture.—W. D. Butler, Fellow; Lithographic drawing of principal front of Roman Catholic College, Kilkenny; and specimens of Irish marbles.

The Architectural Society have passed a resolution expressive of their opinion that the union of their body with the Royal Institute of British Architects would be beneficial to the profession; and have appointed a Committee to confer with the Council of this Institute. The Council have on their part named a Committee of Conference, who have met; and there is every hope that a satisfactory adjustment may accomplish an union which is on so many accounts desirable. Of course a special general meeting of the members of the Institute will be convened to receive the Report of the Council on the matter.

The letters from the Rajah of Tanjore and Col. McLean, Resident, (see Journal X. p. 259) were read; and the Secretary explained the several drawings referred to, consisting of 11 illustrations of pagodas, temples, halls, and palace at Tanjore, Avidiar Coil, Cambaconam &c.; and also the plan of the Island of Sheevasamoodram, presented by Col. McLean.

Mr. Donaldson described the arrangement of a Turkish bath at Bergamo in Asia Minor.

Mr. Griffiths completed his course of papers on Chemistry as applied to construction, by describing the elementary principles of heating and ventilating in buildings.

His Lordship, the President, then concluded by an address to the meeting, enumerating the results of the session, and calling upon the Members to avail themselves of the opportunities afforded by the recess, for procuring information to lay before the Institute during the next session.

Resolved, that the most grateful thanks of the Institute are due to his Lordship for his attendance this evening, and for the advantages resulting to the body from his continued countenance and support.

Adjourned until after the recess.

ELECTRICAL SOCIETY.

At the ordinary meeting on Tuesday evening, the 3rd ult., a communication was read from Mr. Nayler, of Southsea, on the local attraction of iron built steam-vessels; "a property whereby the indications of the compass are made to depart from the truth, except when the ship's head is nearly North or South." The local attraction in ordinary vessels, and the mode adopted for its correction, were described. Mr. Nayler has no doubt that it will be found to follow the same laws in iron as in other vessels, only perhaps under an augmented form; but being once accurately ascertained in its quantity, all danger from its existence will cease, since every course steered can be corrected for it. He however earnestly advises the local attraction to be taken previously to the departure of an iron steamer, and also at the different ports she may reach; for the deviation is not a constant quantity.

LAW PROCEEDINGS.

COURT OF EXCHEQUER, *July 4th.*

LOSH *v.* HAGUE.

This was an action brought by Mr. Losh, an engineer residing near Durham, against Mr. Hague, a gentleman of the same business in London. The complaint made by Mr. Losh was, that, in the year 1837, the defendant infringed a patent obtained by the plaintiff for an improvement in the constuction of wheels for carriages, to be used on railroads. Proceedings having been instituted in the Court of Chancery, an injunction was obtained; for the purpose of sustaining which, and of taking the opinion of a judge and jury in a court of common law, the present action was brought. The defendant pleaded that he was not guilty of infringing the patent of the plaintiff, and that the improvement for which the plaintiff had obtained his patent, was a trifling and insignificant improvement upon the wheels formerly in use.

For the plaintiff evidence was given, showing that the wheels now made by the defendant were no improvement upon the patent of the plaintiff, but were precisely on the same principle, and as nearly as possible the same. The witnesses also stated, that, in 1830, the invention of the plaintiff had brought forward a principle never acted upon before, and one which had rendered the wheels constructed upon it remarkable for their safety and durability.

The evidence for the defendant, on the contrary, went to show that, as long ago as the year 1808, an improvement had been made by a man named Peyton; between which, and that now claimed by the plaintiff, scarcely the slightest difference existed.

Lord Abinger told the jury, that if any part of the wheel made according to the plaintiff's plan, in which part an improvement was stated by the plaintiff in his specification to have been introduced by him, was the same as that previously discovered by Peyton, they must find for the defendant.

The jury consulted for about a minute, and then gave their verdict for the defendant. This cause lasted the whole day. Among the witnesses examined for the plaintiff were, Mr. Nicholas Wood, Mr. Buddle, and Mr. Francis Bramah; and for the defendant, Mr. Roberts of Manchester, Mr. Braithwaite, Mr. Ericsson, &c.

COURT OF QUEEN'S BENCH. *July 6th.*

ROUGH *v.* THE GREAT WESTERN RAILWAY COMPANY.

The Attorney-General (with whom were Mr. Richards and another learned gentleman) as counsel for the plaintiff, said this was an action brought under the following circumstances:—Messrs. Houghton and Baxton, of whom the plaintiff was the assignee, were contractors, who had undertaken to perform a portion of the works on the Great Western Railway; namely, the formation of a number of shafts for a tunnel now being made, and commencing at the village of Box, about six miles from the city of Bath. Being thus employed, Houghton and Baxton were obliged to obtain the necessary machines for the performance of the contract, and they purchased tools and various materials to the value of nearly 4,000*l*. They, however, had the misfortune to become insolvent before this contract was completed. A commission of bankruptcy was issued against them, and the assignees immediately desired to have the machinery, tools, and materials that belonged to Houghton and Baxton, in order to share their value among the various creditors. Upon application to the company for this purpose, the directors would not deliver up the property, claiming it as their own, the contractors having forfeited it by the non-performance of the work agreed upon. The present action was therefore brought by the assignees of Messrs. Houghton and Baxton, to recover the value of the materials and machinery that had been unlawfully detained by the Great Western Railway Company.

Sir Wm. Follett (with whom was Mr. Talbot) appeared for the defendants. He contended that the company were justified in the course they had pursued, as they were entitled to retain the materials and machinery by the contract between themselves and Houghton and Baxton. By that contract it was agreed that in case the works were not proceeded with expeditiously and to the satisfaction of the company, a notice should be served upon the contractors to inform them of it, and to require them to proceed with greater expedition. If that notice was not complied with in less than seven days, the company were empowered to engage other workmen. By another clause of the contract it was arranged, that in case Houghton and Baxton became defaulters, the company might detain the materials and use them until the works were completed. Upon these grounds the learned counsel said he trusted the jury would return a verdict for his clients, and thereby compel the fulfilment of the contract into which Houghton and Baxton had entered with the company.

Evidence having been called, and the Attorney-General having replied,

Lord Denman summed up, and in so doing said that if the jury were of opinion that the company were not justified in detaining the property, their verdict must be for the plaintiff. If, on the other hand, they thought that the contract entitled the Great Western Railway Company to act as they had done, they would of course find in favour of the defendants.

The jury returned as their opinion that the work was suspended sufficiently by the contractors to justify the notice given; and that, upon the notice, the contractors did not comply with it.

Lord Denman: Then I will direct the verdict to be for the plaintiff generally, with liberty to the defendants to move.

PARTY-WALL CASE.

On Tuesday, 17th July, Mr. Thompson, architect, accompanied by Mr. Foxhall the District Surveyor, applied to the sitting magistrates of Great Marlborough-street Police-office, under the following circumstances. That having given three months' notice of an intention to survey the party-wall between the premises, Nos. 111 and 112, New Bond-street, and having been met by two other surveyors (Mr. Henry R. Abraham and Mr. Alfred Beaumont), pursuant to the 38th section of the Building Act, and not having come to any conclusion within the time specified in the Act, they the applicants on behalf of the party giving the notice, require the magistrate to appoint one other, that is a fifth surveyor, to meet and determine the matter.

Sir F. Conant was about to appoint, and named Mr. Cantwell; Mr. Foxhall said that he rejoiced at that gentleman being named, because he was sure he would have the wall down. Upon this Mr. Abraham interposed, and stated that under such circumstances he should object to any appointment whatever. He then pointed out an informality in the notice, which was laid under the 38th section, relating solely to state and condition, whereas it should have been given under the 39th section which refers to thickness. Mr. Foxhall and Mr. Thompson contended, that the word condition comprehended both repair and sufficiency of thickness. Mr. Abraham replied, and Sir F. Conant after a patient hearing of rather a warm discussion, decided that as the clauses were distinct and explicit in their separate uses, the alleged informality was fatal, and he should decline naming a fifth surveyor. Three months' further notice must therefore be given by the applicant.

STEAM NAVIGATION.

Great Western Steam-Ship.—Bristol, July 8, Half-past Five o'clock, P.M.—The Great Western steam-ship, Captain Hoskin, R. N., commander, cast anchor this afternoon in Kingsroad, at about half-past two o'clock, having performed the home ward passage in the wonderfully short space of twelve and a half days. The outward-bound voyage was accomplished by this splendid vessel in fourteen and a half days, having sailed from Bristol, June 2d, and reached New York, June 17th, at four A.M.; which place she left for Bristol, June 25th, at five P. M. Thus she has performed the whole voyage from Bristol to New York, and back again, in the unparalleled short space of thirty-six days, eight of which were spent at New York, which leaves her four weeks for the actual voyage, which generally averages as many months by sailing vessels. The Great Western has brought over ninety-two passengers, all of whom express themselves in terms of the greatest delight and satisfaction with the splendour and comfort of her accommodations, and seem quite enraptured in making mention of the very slight motion felt on board the vessel throughout the passage, even when blowing hard; and during the latter part of the voyage they encountered heavy weather, which gave them every opportunity of judging of the great advantages possessed by the vessel in this respect. A passenger, with whom I had an opportunity of conversing, told me that he had several times crossed the Atlantic in sailing-packets, and in very similar weather to that experienced on his voyage home in the Great Western, and that he should not have believed it possible for such a difference to exist, had he not felt and tested it himself. Even in the roughest weather it seems that passengers may sit down to dinner without any of the fears or dangers of accident on board sailing vessels. You feel assured that you will not be laid sprawling on the cabin floor by your chair lurching to leeward, nor thought desirous of appropriating to yourself more than your share of eatables by getting the contents of half-a-dozen or more dishes poured wholesale into your lap. None of these or others somewhat similar, but even more disagreeable accidents, so frequent but unavoidable on ship-board, *are here felt; in fact, you may sit down and enjoy yourself almost in as much* ease as in a drawing-room on shore. This comparative tranquillity and slightness of motion is mainly to be attributed to her great length, which enables her to cut through several waves, into the troughs of which shorter vessels must of necessity roll, and become, as it were, "swallowed up." Vessels of great length must, therefore, of course, by reason of their powers, not only be much easier, but must also save very considerably in the time and distance occupied by vessels of ordinary length in rising and falling from the troughs of these seas. The Sirius reached New York on the 18th of June, at four o'clock P. M.; the Great Western having arrived the day previous at four o'clock A. M. The Great Western passed Sandy Hook at seven P. M. of the 25th of June, and from this time to the time of seeing Trevose Head, in Cornwall, was exactly twelve days. The average distance run on the outward voyage was about nine miles per hour, and on the homeward voyage rather more than ten miles per hour.—*Standard.*

STATEMENT OF THE GREAT WESTERN'S SECOND OUTWARD VOYAGE.

Date.	Sails set.	Winds.	Course.	Distance steamed	Average number of strokes of the Engine.	Pressure.	Vacuum in Condenser.
June 3	None	W., strong ..	S. 82 W.	164	11	3	29
June 4	Fore sail and fore-top sail, and fore and aft sails	N.E. mod.....	— 80 —	232	12	3¼	29¼
June 5	Mostly none..	N.E., calm ..	— 89 —	260	12	3¼	30
June 6	Same as 4th ..	S.W., mod. ..	— 75 —	250	12	3	29½
June 7	Fore and aft sails	S.W., fresh ..	— 80 —	242	12½	3	29¼
June 8	None	S.W., very do.	— 78 —	184	10	2½	30
June 9	Same as 4th ..	N.N.E., mod.	— 70 —	207	12	3	30
June 10	None	calm	— 71 —	246	14	3¼	29¼
June 11	None	W., fresh	— 72 —	199	11	3¼	29¼
June 12	None	W., ditto	— 79 —	208	11¼	3¼	29¼
June 13	None	W., very fair..	— 80 —	187	13	2¼	30
June 14	None	W., fresh	— 77 —	181	14¼	3¼	29¼
June 15	A.M. same as the 4th; P.M. none	N., moderate.	— 80 —	218	15	3¼	29¼
June 16	Same as 4th ..	W., ditto	— 87 —	227	16	3¼	

At 7 45 P.M., June 16th received a pilot on board; at day-light, 17th, made Neversink highland, crossed the bar at half-past four, and at the wharf at three quarters past six. Number of strokes of the engine, 276,215.

The British Queen.—This stupendous steam-ship, commanded by Captain Roberts, formerly of the Sirius, arrived at Port Glasgow on Saturday the 14th ult., and went into dock, where she is to receive her machinery. The Queen left Gravesend on Monday week, the 9th, and was towed to Plymouth by the Vulture steamer. Betwixt these places she had foul winds. At Plymouth the Vulture left, and the Queen then came right round by the Land's End herself in fine style, carrying all sail, and beating every vessel in her way, especially a French brig, which attempted to compete with her for some time. Having arrived at the tail of the bank early on Saturday morning, she was towed into the wet dock at eleven by the Samson steamer, the top of whose funnel, it was observed, just reached the top of the Queen's paddle-box.

The Bristol and American Steam Navigation Company have contracted for the immediate building of three large and splendid steam-ships to run between Cork and New York, in conjunction with the British Queen; they are to be christened President, Great Britain, and United States. The keel of the President has been already laid; she is to measure 2,028 tons.

An American Steamer crossing the Atlantic.—The Richard Anderson, Lucas, which left Charleston on May 27th, reports that on June 8th, in lat. 46 long. 30, she passed the City of Kingston steamer, from Baltimore for London, under canvass.—[The steamers which start from the United States do not seem to make very flourishing passages, when they let sailing vessels pass them on the way. It is something like the old story of the Stockport stages, which pedestrian travellers would not patronize, because they were in a hurry.]—*Manchester Guardian.*

The Royal William.—This vessel adventured an experimental trip in the Mersey on Tuesday, the 3rd ult., in order to test the efficiency of the alterations which, since it had been determined she should cross the Atlantic, have been devised and adopted. The result of this trial was eminently successful. In order to diminish the mass of coal which it had been calculated the furnace would consume, it had been contrived that a certain portion of turf should be mixed with the fuel, an expedient which it was imagined would not merely diminish the amount of dead weight, but would communicate heat to the boilers in a shorter space of time than would be occupied were the fuel to consist of an unadulterated quantity of coals. It has been ascertained, by careful and minute examination, that the admixture of turf will enable the Royal William to accomplish a voyage exceeding by one thousand miles the distance between New York and Liverpool. Another incident which occurred in the course of this experimental trip, affords a gratifying indication of the progressive improvements in steam navigation. During two hours, two only of the three boilers of the packet were used, and yet the speed of the vessel was not diminished. In the event of accident therefore, it will be an easy matter to repair damage without interrupting the average rate of progress of the vessel. This packet, it may confidently be predicted, sets forth on her trip more completely equipped to encounter the chances and obstructions which she is to brave, and better qualified by her surpassing capabilities to narrow the space which separates the States from Great Britain than any of her competitors.—*Liverpool Paper.*

The Royal William (steamer), for New York, with 40 passengers, left the George's Pier Head at six o'clock this evening, being the first steamer that has left the second commercial port in the kingdom. She was accompanied by several other steamers belonging to this port, which were crowded with spectators of all denominations.—*Liverpool, July 5.*

The New Steamer, Tiger.—This steamer belonging to the St. George Company, made her first experimental trip on Thursday, June 14; and seldom have we witnessed a more gratifying proof of the ingenuity of man than this gallant vessel presented. Her form is perfect symmetry, and nobly does she walk the water. She is one of the largest class, her size preventing her admission into any of the Liverpool docks. She is propelled by engines of 300 horse power, with expansive valves; and is fitted up with Mr. Samuel Hall's patent condensers. They are from the manufactory of Mr. Edward Bury, of this town; and in beauty of structure, combined with strength and durability, challenge competition: we recommend any person desirous to see first-rate machinery to visit the Tiger. The bed plates and condensers (cast in one piece) are a curiosity, and, we are informed, are of the enormous weight of 16 tons 8 cwt. and 16 tons 6 cwt. respectively. Her speed is very great, and from her performance on the first trial it is believed that she will surpass, in this respect, any vessel out of the port. We congratulate her spirited company on the acquisition of such a boat; and if, as we have heard, they intend despatching her to New York, we have no doubt that her passage will be performed in less time than it has yet been accomplished in. Go where she may, she will reflect credit on all parties concerned; and—success attend her, say we.—*Liverpool Chronicle.*

The Liverpool.—This magnificent steam-vessel, the property of Sir John Tobin, which has been lying for some months in the Trafalgar Dock, has begun to get her machinery on board. The dock trustees, in order to facilitate the operation, have erected cranes, &c., on the quay; and, the machinery being nearly all ready, she will be equipped for sea in the course of September next. Should Sir John not, in the meantime, dispose of her, it is highly probable that, should the prospects of transatlantic steam navigation become promising, the Liverpool will make her first trip to New York.—*Liverpool Mail.*

Steam Navigation to New York.—An incident showing the importance to Liverpool of a direct intercourse by steam vessels to New York, occurred last week, which strongly illustrates what we have before urged—namely, that the establishment of a line of steam vessels, taking their departure from Liverpool with the same regularity and punctuality which hitherto have distinguished the sailing packets, will make it the leading point for arrivals and departures, not merely for England but for the continent of Europe. On the advertisement of the sailing of the Royal William, for New York, on the 5th of July, being advertised in the London papers, several applications were forwarded from Paris, engaging berths in that vessel, and transmitting the amount of the passage money, the parties undertaking to be in Liverpool in time for the Royal William's departure. The railroad from London to Liverpool aids in no small degree that expedition and certainty which are essential to travellers. The proposal to insure the Royal William to and from New York for 20,000*l.*, one-half in London and the other in Liverpool, was taken, and the list filled at the underwriters' rooms in two hours from the time the risk was put on the books.—*Liverpool Mercury.*

The Sirius.—This fine steam-ship which is now on her second voyage to New York, is intended to be established as a packet between London and St. Petersburgh. She will leave London on the 1st of August on her first voyage. This will be a great accommodation for persons intending to visit the Russian capital; and we have no doubt the shortness of the passage will induce many travellers to go to that country who never before thought of such an excursion.

Liverpool and Brazil.—The second vessel for the line of steam-packets on the coast of Brazil, was launched on the 10th ult., by Messrs. Humble and Milcrest; she is called the Bahiana, from the port of Bahia, being the first at which the packets are to touch after leaving Rio de Janeiro. The Bahiana will proceed in a few days to join the St. Sebastian, at Hawarden, on the River Dee, to take her engines on board. —*Liverpool Paper.*

Steam Navigation on Canals or on the Severn.—The Manchester Guardian gives an interesting account of the performances of a small iron steam-boat, called the Jack Sharp, belonging to the Mersey and Irwell Navigation Company. She is about 65 feet long, 13 or 14 feet broad, and propelled by a common marine steam engine of twelve horses' power; the paddles are also of the common kind, but placed at the stern of the vessel, one on each side of the rudder; the chimney is far forward, and the engine above the paddles, which are connected with it by spur wheels. The boat draws about two feet eleven inches water without passengers, and when full (she has carried 120 persons) she draws about four feet water. The fuel used is coal; and it is stated that, although her power is twelve horses, she does not work more than seven. The vessel has no mast or sail, so that her performance is all steaming. She has a cabin, but most persons remain on deck. The engine projecting above the level of the main deck, its cover forms a sort of quarter-deck for the captain and the man at the helm. We understand her average performance during the week has been at the rate of 7 miles per hour. Her Captain states *that she does not cause the washing away of the banks, even to the same degree as the packets now plying on the river drawn by two horses.* The boat and engine were constructed by Mr. Jones, of St. Helen's. Could not such a vessel be introduced with advantage during a large portion of the year between this city and Worcester; and also on the Berkeley Canal, provided that steam navigation was extended from hence to Bristol? It seems most extraordinary that whilst there is scarcely a river in the kingdom suited for the purposes of navigation, on which steam has not been most successfully introduced, up to

the present moment, with one exception some years since, it should be unknown on the Severn. We have received more than one communication on the subject, particularly with reference to a steam communication between this city and Bristol. Such a steamer as that described above, fitted with patent paddles which make no backwater, would, we are persuaded, overcome any existing difficulty. The subject is worth attention. We perceive from our Hampshire contemporaries that a steam communication, which has just been established by a London company between Poole and Southampton, has been attended with astonishing success. We mention the fact to show what may be done in other neglected localities.—*Gloucestershire Chronicle.*

Iron Steam Packet.—On Saturday, June 23, an elegant wrought-iron steam packet, belonging to the Eagle Company, was launched from the Iron Steam-boat Building Establishment of Messrs. Ditchborn, More, and Co., next to the Victualling-office, Deptford. A numerous company was assembled, and she went off amid shouts, clapping of hands, and rejoicing. Of the superior speed, safety, and accommodation of this boat, there can be no doubt; nor of her amply remunerating the spirited owners who are the first to place a perfect iron steam packet for a regular passage trade on the River Thames. She was originally intended to ply with two others of the Company's boats between London-bridge and Woolwich, calling at Blackwall; but the Directors have since found it necessary to extend their line from Waterloo-bridge to Gravesend, still touching at Blackwall. The engines are by Miller, Ravenhill, and Co. The hull of this vessel being built entirely of wrought-iron, excludes the possibility of danger by fire; and being divided into three compartments by perfectly water-tight iron bulkheads, is equally secure from sinking.—*Sun.*

Iron Boat Worked by Ericsson's Propellers.—An iron vessel, constructed at the building-yard of Mr. John Laird, at North Birkenhead, called the Robert F. Stockton, fitted with Ericsson's propellers, and intended as a tow-boat on the Delaware and Raritan Canal, in the United States, was launched on Saturday the 8th ult. All her machinery, with the exception of the boiler, which will be ready in a few days, was on board at the time. She will be schooner-rigged; and, as soon as she is fully equipped, it is the intention of Mr. Ogden, the United States' Consul at this port, under whose inspection she has been built, to try her on the Mersey. From the experiments which have been made with the twin-boat, the Francis B. Ogden, on the Thames, sanguine hopes are entertained that the propellers, worked by steam, will give the boat an average speed of six or seven miles an hour; and should they be found applicable to sailing vessels, they will produce an important revolution in ocean navigation.—*Liverpool Mail.*

The French Steamer of War Meteor is lying in the river Thames, off the Tower, and is a fine craft. She is painted black, with brass tompions in her guns; her crew are short healthy-looking lads, but her marine artillerymen are fit for grenadiers. Visitors are received by the gallant officers with the greatest urbanity.—*United Service Gazette, July 2.*

A direct intercourse by steam has been lately established from Dublin to Paris; the distance is accomplished in about 45 hours.—A direct steam communication is about to commence between the Thames and the Shannon—London and Limerick.

Enormous Plate of Iron.—We were lately shown in Messrs. Fawcett, Preston, and Co.'s yard, two plates of iron, which are said to be the *largest ever made.* They measure 10 feet 7 inches long, 5 feet 1 inch wide, and 7-16ths of an inch thick, and weigh between 7 and 8 cwt. They are intended for the bottom plates of two steam generators on Mr. Howard's plan, and were made by the (Colebrook-dale Iron Company, Shropshire; who, we were informed, are the only company in Britain (we may say in the world) that can make plates of this size, or even approaching to it.—*Liverpool Standard.*

PROGRESS OF RAILWAYS.

Hull and Selby Railway.—We are glad to be enabled to inform our readers that the works on the foreshore, near this town, in connexion with the railway, have been in progress during the last three weeks, and every exertion will be used in order to complete the embankment in the course of the present summer. We are informed that several hundred men are employed on other portions of the line; and that the works of the Hessle contract especially will be carried on both day and night during the summer. An advertisement appears in our paper to-day for tenders for the erection of the bridge over the Derwent, and for the two remaining portions of the line which have not yet been contracted for, viz., from Melton to the Eastern extremity of the Market Weighton embankment, and from the River Derwent to the junction with the Leeds and Selby Railway at Selby. In a short time therefore the whole of the works will be in progress from one end of the line to the other. The directors have contracted for 1,500 tons of iron rails, in addition to previous contracts to the extent of 2,000 tons, making 3,500 tons in the whole. They have also agreed for six locomotive engines, and for all the land required between Hull and Selby, a considerable portion of which is paid for, and conveyed to the company. Of the third call of 5*l.* per share lately made, upwards of four-fifths have been received; and there is every reason to expect that this important line of railway will be opened early in the spring of 1840, agreeably to the intentions of the directors, to the great benefit of the town, the districts through which it passes, and with which it will communicate.—*Hull Advertiser.*

Opening of the Newcastle and Carlisle Railway.—The Berwick and Kelso Warder gives a long account of the opening of the whole line of railway from Newcastle to Carlisle, a distance of sixty miles, on Monday, June 25; and remarks, that although many of its readers may have no immediate connexion with either of these places, they can yet scarcely avoid being interested, more or less, in an event which consummates so signal an achievement of enterprise and scientific skill; and by effecting so rapid and easy a means of communication, not merely between two large and important towns, which may be regarded as the capitals of their respective districts, but between two extremities of the island—the German Ocean being on one side, and the Solway Firth on the other—affords so favourable an opportunity of extending the commerce of the whole North of England and South of Scotland, and thereby acting directly and most beneficially on its agriculture likewise.

Maryport and Carlisle Railway.—A meeting of the Directors was held at Aspatria, on Wednesday the 20th ult., to receive the report of Mr. Hall, the superintendent engineer, as to the progress of the work; every part of which is proceeding in the most satisfactory manner, as much so as the company could possibly expect or wish for. The numbers of men are increased as fast as the nature of the work will admit of: at present about 250 are employed; and it is satisfactory to state, that no impediments or difficulties have hitherto occurred, but every part of the undertaking is progressing with the greatest spirit and good feeling. The diversion of the river near Nether Hall is almost completed, and various other smaller diversions are in a forward state. The mason-work of some of the principal culverts is completed, and the stone-work for the largest bridges is in a state of great forwardness. It is unnecessary to state, that Mr. Hall's report was highly gratifying to the Directors; and, altogether, the prospects of this Company are flattering in the extreme.—*Whitehaven Herald.*

Morecambe Bay Railway.—Mr. Hague has arrived at the seat of his labours, and he is now busily engaged, with able assistants, in determining the points at which the railway ought to cross the Lancaster Sands, and in ascertaining the nature of the substratum. It is rumoured that Mr. Rastrick will be associated with Mr. Hague in a survey of the entire line.

Great North of England Railway.—The contractors for the railway bridge which is to cross the river Ouse at Poppleton, near York, have commenced operations upon the works; the navigators and carpenters are actively employed in excavating, &c., for the foundations. We understand that a temporary bridge will be thrown across the river, preparatory to their proceeding with the stone structure which is contracted for.—*Hull Advertiser.*

Lancaster and Preston Railway.—On Thursday June 28th, the day of the coronation, the first stone of the viaduct at Galgate, on the line of this railway, was laid by Mr. Alfred Jee, the resident engineer; the contractors and many others being present. A number of Victoria medals, kindly presented by some gentlemen of the neighbourhood, were deposited underneath the stone. This viaduct, which crosses the River Condor and the road at Galgate, will be one of the largest works on the line, and is to consist of six arches, each thirty feet span, and between forty and fifty feet high. It is to be built entirely of stone. The other works at this end of the line are proceeding with great activity; and a commencement has also been made near Preston.—*Lancaster Guardian.*

Manchester, Bolton, and Bury Railway.—We have great pleasure in stating that the traffic on this line of railway, which was opened some weeks ago, is rapidly increasing. The average number of passengers conveyed is about 1,200 a day,—a greater number than had been previously calculated on as likely to travel upon it. The stage-coaches which used to run between Manchester and Bolton are nearly all discontinued, the proprietors finding it a losing concern to compete with the railway. The applications to the company to carry goods are numerous; and there cannot be a doubt that, as soon as the arrangements are completed, the quantity of produce and manufactures conveyed along the line will be greater than the estimates formed by the projectors of the railway.—*Preston Observer.*

Leeds and Manchester Railway.—The works in this neighbourhood have been contracted for, and will, we understand, be commenced immediately.—*Halifax Express.*

A railway from Stockport to Macclesfield is to be immediately commenced; and it is expected that a line of railway from Manchester to Stockport will be simultaneously laid down.—*Liverpool Journal.*

Midland Counties' Railway.—The following is the engineer's return of the number of men and horses employed on the works of the Midland Counties' Railway, on the 30th of June, and of the quantity of earthwork excavated from the 5th to the 30th of June:—4,038 men; 385 horses; and 213,933 cubic yards of earthwork.

Birmingham and Derby Junction Railway.—The works on this line are advancing very rapidly, and the contractors are bound under heavy penalties to have the railway completed and open to the public, by the 30th of June next. A general meeting of the proprietors was held on the 3rd ult., at Dee's Royal Hotel, Birmingham, when consent was given to the new bill, which has passed the House of Commons, and is now before the Lords, to alter the line of this railway between Coleshill and Stonebridge, and which is being obtained at the expense of the Earl of Aylesford. The new line will leave the present one on the Coleshill side of Great Packington, and proceed through the parishes of Little Packington, and Bickenhill, and join the London and Birmingham Railway one mile nearer to the latter town than the line proposed to be abandoned. The new line is a quarter of a mile longer than the old one; but the levels are much better, and there will be a saving to the company of at least 6,000*l.*—*Daily Paper.*

London and Birmingham Railway.—It is reported that the 10th of September is the day fixed for opening the whole of the railway line.

Aylesbury Railway.—We observe from a circular lately addressed by the Chairman of the Directors to the Shareholders, that the whole of the land required for the railway has been purchased at prices within the sum originally estimated; and that the contract for making the railway has been let to Mr. J. R. Chapman, one of the most experienced contractors on the London and Birmingham line, at a sum below the engineer's estimate, under a penalty to complete the same by November next. It appears, by the report of the resident engineer, that he is advancing in his works with great rapidity—that about one-third part of the earthwork of the whole line is completed, and that the brickwork is also in great forwardness, and the embankment is made up at the point of junction with the London line.

The London and Southampton Railway, it is reported, will be open on the 1st of September next, as far as the great western road leading to Exeter, and the Southampton end as far as Winchester—making in the whole 53 miles of this great undertaking completed.

Newtyle and Glammis Railway.—This railway was opened on Monday, June 4, for the conveyance of passengers. The coaches run four times a week; and, as on the Coupar Angus line, the hours are made to suit those of the Newtyle Railway. The railway brings a district within its range, travelling from or to which has always been difficult; and we anticipate that it will soon supersede other conveyances to Kirriemuir and the other populous places in the district.—*Perthshire Courier.*

Glasgow, Paisley, and Ayr Railway.—The works are commenced on the whole line, except a portion between Paisley and Dalry, which will, however, be the next contracted for. It is expected that the joint line from Glasgow to Paisley, made at the expense of this company and the Greenock, in equal portions, will be ready to open next summer. A report was circulated at Liverpool, originating in a misinterpretation of a passage in the report of the Greenock Directors to their shareholders on the 2nd instant, that the Ayrshire Directors contemplated adopting a gauge of 5 ft. 0 in. for the rails. This point may be now considered as set at rest by the distance being fixed at 4 ft. 8½ in., the usual width, on the advice of Mr. Locke.

Glasgow and Greenock Railway.—The first stone of this railway was laid with masonic honours on Thursday, June 14th.—*Caledonian Mercury.*

Glasgow and Ayrshire Railway.—The foundation-stones of the bridges over the Garnock and Irvine rivers were laid with great ceremony on Thursday, the 28th ult.

Dublin and Drogheda Railroad.—The works of this great national undertaking will commence immediately. The contract for the first seven miles and a half—namely, from the Royal Canal, near the North Strand, to Stapolin, in the county of

Dublin, has been taken by Mr. Weakes, an eminent builder from Wexford. The contract for the remainder of the line remains still open, but the contractors will shortly be declared. For the portion which Mr. Weakes has got, his estimate was 49,000*l*. Mr. Dargan, who was the contractor for the Dublin and Kingstown line, put in an estimate for the same distance at 85,000*l*. Messrs. Doolin, Bennet, Henry, and Co., put in an estimate at 72,500*l*. It is gratifying to state that although there has been considerable delay, the shareholders will be benefitted by the reduced rate at which the work will be done, owing to various discoveries in that species of mechanism applicable to railroad making, and the increased skill which experience must bring to the performance of any difficult task. Some four or five years ago there was comparatively little known of railroad works.—*Dublin paper.*

Railway Speed.—The Sun engine, which brought down the seven o'clock train from Manchester last night, accomplished the distance—31 miles, to the mouth of the tunnel—in the short space of 41 minutes. This is at the rate of one mile in 80 seconds, or 45 miles per hour.—*Liverpool Journal, June 16.*

Railway conveyance is daily adding value to all sorts of agricultural produce. "We have heard," says the *Shrewsbury Chronicle*, "an extensive Staffordshire grazier state his confident opinion, that, were a railway constructed from Birmingham to Shrewsbury, it would increase, by 1*l*. per head, the value of every fat beast in the counties of Montgomery and Salop, by the facility it would afford for conveying them, without loss or delay, to the markets where they are chiefly consumed."

Conveyance of Sheep by Railways.—On Friday, a train on the London and Birmingham Railway, impelled by three engines, conveyed 1,652 fat sheep from Denbigh-hall to London. The opinion of the drovers, who may be supposed to understand the subject as well as any others, and are less likely to be prejudiced in favour of the utility of railways for this purpose, is, that the old mode, when the railway is complete, will be superseded; not that the expense is materially lessened, but that the animals arrive at their destination from 5 to 7 per cent. more valueable than after a journey of 50 miles by the road.—*Bucks Herald.*

A Locomotive Village.—The Messrs. Lyons, coachmakers of this city, are building a small moveable village for the Utica and Syracuse Railroad. This company have now on their road two steam-engines, which drive the piles upon which the road is built, and saw them off at the proper level; the rails are then laid, and the road completed as they go along. The "village," consisting of a number of neat looking cottages, is to be placed on the road in rear of the pile-drivers, for dwelling-houses for the mechanics and labourers on the road. Improvements will never stop; and we shall yet see the time when one may take a tea-kettle in his hand, put a few chips in his pocket, get astride a broomstick, and go where he pleases.—*Utica Democrat.*

Railway Casualties.—For 471 detentions on the Grand Junction Railway the following causes are assigned:—

Broken axles of engines, tenders, and waggons	19
Failure of pumps, eccentrics, connecting-rods, cotters, &c.	34
Bad coke and fires burnt out, &c.	42
Heavy trains	59
High winds	25
Obstructions from cattle waggons, and breaks down	13
Detentions from goods and second-class trains, &c., on Liverpool and Manchester Railway	107
Engines more or less out of order, the number not being sufficient	68
Rails slippery	26
Detentions in watering	22
Horses kicking out the sides of horse-boxes	4
Waiting for London mails at Birmingham (time deducted)	7
Engines and waggons getting off the road at points	6
Waiting for Manchester train at Warrington	39
Total	471

—*Commons Paper*, No. 267.

Private Bills.—As a proof of the manner in which private Bills are often smuggled through the Houses of Parliament, the Aylesbury News states, that the first intimation the inhabitants of Aylesbury and Thame had of the Aylesbury and Thame Railroad Bill was the notice in the papers of last week, that the Bill had received the Royal assent.

Railway Mails.—It may not be generally known that for some weeks past a carriage has been travelling on the London and Birmingham Railroad in which the business of a post-office is conducted. Letters are taken in, sorted, and left at different stations on the line. The progress, however, of the train has been considerably retarded by the necessity of stopping it to take up and leave letter-bags. This difficulty has at length been obviated by a plan recently submitted to the Post-office authorities, by a gentleman who has invented a means of exchanging the mail bags at the various stations in question, without in the least checking the speed of the train; and from the experiments which have been tried on the railroad above referred to, in the presence of the directors, engineers, and proper officials, it has been satisfactorily proved that by the adoption of this plan, the bags can be exchanged without danger or difficulty, and with certainty, at whatever rate of speed the carriage may be travelling. Upon several occasions this desirable object was accomplished at a rate equal to thirty miles an hour.

Cheap Travelling.—Henceforth no foot passengers will be allowed to travel on the railway between Stockton and Middleborough; but carriages will be attached to trains to carry travellers at *two pence* each! The distance is four miles.

ENGINEERING WORKS.

Westminster Bridge.—In consequence of the defective and dangerous state of the piers of this bridge, owing to their having been built in caissoons and lowered down to the bed of the river without removing the stratum of gravel and sand, the current which has become very strong since the removal of old London Bridge, is by its constant action completely undermining the whole fabric. The engineer likewise neglected the precautionary measure of fixing sheet piling round the piers, excepting in the case of four: the consequence is, that all the remaining piers must now be surrounded with coffer dams, for the purpose of effectively securing the foundations. This will be done by driving sheet piling into the substratum, which is clay; as well as other measures for the security of the foundations. The works have commenced, under the direction of Messrs. Walker and Burgess; Mr. Cubitt, of Gray's Inn Road is the contractor: amount of tender 67,000*l*.

Suspension Bridge from Hungerford Market to Lambeth.—This work is about to be commenced immediately, under the direction of Mr. Brunel; Messrs. Grissell and Peto are the contractors.

Ardglass Lighthouse.—A lighthouse has been commenced at Ardglass; the foundation was laid towards the end of June. We hope soon to have similar intelligence to give respecting a lighthouse at St. John's Point.—*Down Recorder.*

Granton Pier.—The Caledonian Mercury gives a long account of the festivities in honour of the opening of this pier and of her Majesty's coronation on Thursday June 28. It was named the Victoria Jetty.

The Caledonian Canal.—This truly magnificent work consists of a series of canals and navigable locks, extending from Corpach Basin, in the tideway of Lock Eil, at the north end of Linnhe Lock, near Fort William, to the Moray Firth, on the west side of Inverness. The total length of this navigation is 60½ miles, of which 23 miles are artificial cutting, and the remaining 37 miles are natural lochs or lakes, which have been rendered navigable. This canal being projected chiefly with a view to facilitate the trade between the Baltic, the western ports of Scotland and Ireland —is 15 feet deep throughout; its surface breadth is 120 feet, and its breadth at bottom 50 feet. Its summit level is 91 feet above the sea at low water; it has 28 locks, which are each 172 feet long. Eight of these locks, situated at the eastern side of this navigation, to which the name of Neptune's Staircase has been given, are considered to be works of the very first order, and to attest the skill of the engineer, the late Mr. Telford. The cost of this canal, according to the report of the Commissioners appointed for superintending its execution, was 1,005,770*l*.; it was opened for traffic in October, 1822, but has hitherto been but little used, and as a speculation may be considered unprofitable. The tolls received in the year ending 1st May, 1835, were 2,232*l*., while the cost of maintaining the canal during that year was 3,596*l*., leaving a deficiency upon the year of 1,188*l*., exclusive of any charge for interest on the capital expended. This result may in part be attributed to the discriminating duties upon European timber in favour of our North American colonies, which has materially interfered with the branch of trade upon which reliance was chiefly placed for producing an adequate return for the capital expended. It appears from a report recently made by the Commissioners to whom the management of this canal is entrusted, that the traffic upon it is increasing. In the winter of 1836-37, several Baltic trading vessels passed through, and the further employment of steam vessels has opened a considerable traffic in sheep and black cattle between the Highlands and Glasgow.—*Progress of the Nation.*

ENGINEERING WORKS IN SCOTLAND.

The principal engineering works in course of execution in Scotland, on which bills have been obtained, are the following. Those marked * have not as yet been commenced.

* Edinburgh and Glasgow Railway	Engineers,	Grainger and Miller.
Glasgow and Greenock Railway	„	John Locke.
Dundee and Arbroath Railway	„	Grainger and Miller
Slamannan Railway	„	J. Macneill.
Wishaw and Coltness Railway	„	Ditto.
Glasgow, Ayr, and Kilmarnock Railway	„	Grainger and Miller.
Grangemouth Harbour and Dock	„	J. Macneill.
Forth and Cart Junction Canal	„	Ditto.
* Campsie Canal	„	Ditto.
* Blockhairn Canal	„	Ditto.
Paisley Water Works	„	— Thom.
Granton Harbour and Pier	„	J. Walker.
Edinburgh and Newhaven Railway	„	H. H. Price.
Dalkeith and Leith Railway	„	— Rankine
Polloc and Govan Railway	„	J Macneill.
Port Glasgow Docks	„	J. Walker.
River Clyde Navigation	„	Ditto.
River Cart Navigation	„	J. Macneill.

There are also considerable improvements in course of execution in the Docks at Dundee and Aberdeen.

NEW CHURCHES.

St. James's Church, Holloway.—On Tuesday, June 19th, the first completed of three district churches now in course of erection in the parishes of Islington and Holloway, was consecrated by the Right Rev. the Lord Bishop of London. The architectural character of the building is Grecian; it was designed and executed under the superintendence of Messrs. Inwood and Clifton, the architects. It is calculated to accommodate 1,100 persons, 300 of whom are provided with free sittings. The whole cost of the building has not exceeded 3,200*l*., out of which "The Bishops' Fund" has contributed 1000*l*., and the remainder has been raised by voluntary contributions of the parishioners.

All Saints Church, King's Cross.—On Thursday, the 5th ult., the above structure, which is the second completed out of three district churches within the parish of Islington, underwent the ceremony of consecration by the Right Rev. the Lord Bishop of London, in the presence of a crowded congregation. It was designed and executed, in the Gothic style of architecture, by W. Tress, Esq. It is calculated to accommodate 1,000 persons, to nearly 300 of whom are allotted free sittings; the whole cost of the building will not exceed 3,200*l*., 1,000*l*. of which is subscribed by the Metropolis Churches Fund, and the remainder by the voluntary subscriptions of the parishioners.

Lambeth.—The Archbishop of Canterbury has given a piece of ground in Carlisle Lane, upon which a chapel will be forthwith erected, which will, when completed, afford accommodation for 1,000 persons. The cost of the building (3,400*l*.) will be defrayed by the commissioners appointed for the rebuilding of churches, &c. Edward Blore, Esq., of Welbeck-street, Cavendish-square, is the architect.

St. Helen's.—A new church is about to be built at St. Helen's, by P. Greenall, Esq, one of the Tory Candidates for Wigan at the last election. The foundation stone was laid by his lady on the day of the Coronation. The church is to be built in the early pointed style; of brick, with stone dressings, pinnacles &c. The nave will be 90 ft. by 30 ft.; and the transepts 67 ft. by 30 ft. It will have galleries at the West end and in the transepts; and is calculated to contain 960 persons, and to cost £3,500. The tower, to which there will be no spire, is to be about 13 ft. square, and 70 ft. high. Messrs. A. and G. Williams of Liverpool, are the architects. K. C.

Church for the Blind and the Deaf and Dumb.—The beautiful church between the Blind Asylum and the School for the Deaf and Dumb, at Old Trafford, was opened for the permanent celebration of divine service on Sunday, June 10th.

Holy Trinity Church, Freckleton.—This new church was consecrated on Wednesday, June 13th, by the Bishop of Chester. It is a neat building of brick and stone. Its dimensions inside are 58 feet long by 27 wide; outside, 80 feet long; and the tower and spire are elevated 58 feet. There is no gallery in the church, but precautions have been taken to allow one to be put in, and as his lordship recommended such an addition, it will most probably be made. The present accommodations are 350 sittings. Mr. Latham, the architect, of this town, had the superintendence of the erection, and the very neat and chaste appearance of the building is highly creditable to his skill.—*Preston Pilot.*

St. Mary's Church, Preston.—This new church, which is situate in Blacow-street, at a short distance from the House of Correction, was consecrated on Wednesday, June 13th, by the Bishop of the diocese. It is built of hewn stone in the Norman style of architecture. Its inside dimensions are 72 feet long by 42 feet wide; and the outside extreme extent, including both the tower and chancel, is 108 feet. The height of the spire from the threshold to the finial, is also 108 feet. The accommodations in the body of the church and the two side aisles, are for 600 persons, and in the gallery which is a front one, and very spacious, being 50 feet in depth, 500 sittings are provided. The reading desk is placed on one side of the church, near the communion, and the pulpit on the other. The altar screen, behind which is the vestry, is at present in an unfinished state, but is intended to consist of a succession of arches, with deep pillars and mouldings. The noble Norman arch, with its massy pillars, which seems to enclose and guard this portion of the sacred building, has a very imposing effect, and bears a strong resemblance to, though it is not throughout an imitation of, an arch in the venerable cathedral at Durham.—*Preston Pilot*

PUBLIC BUILDINGS AND IMPROVEMENTS.

The Reform Club.—This building is about to be commenced immediately on the site of the old building adjoining the Travellers' Club-house, Pall Mall. A description of Mr. Barry's Design was given in No. 4 of our Journal page 67. Messrs. Grissell and Peto are the contractors: amount of tender, under 38,000*l*.

The Entrance to the Birmingham Railway at the Terminus, Euston Square is, now finished; the massive iron gates were fixed during the last month.

Bartholemew's Hospital.—Considerable additions are to be made to this building; it is reported to the amount of 22,000*l*.

Bethlem Hospital.—The first stone of a very extensive addition to this great institution was laid on Thursday, July 26th; Sydney Smirke, Esq. is the Architect.

Liverpool, July 8, 1838.—The so-called foundation stone of the St. George's Hall was laid on the Coronation day, on land in Lime Street; the Town Council reserving to themselves the right of removing it to any more convenient part of the same ground. It is intended to advertise for designs (which it is to be hoped will be publicly exhibited); and it is expected that the leading architects of the country will contribute.

The Apothecaries' Hall is approaching completion, the company having taken possession of part of the premises. It is said to have cost twenty thousand pounds already, and they talk of laying out a thousand in the fittings up alone of the sale room. It is rather an extraordinary building; and perhaps the architects Messrs. Cunningham and Holme would furnish drawings of it for the instruction and amusement of your numerous readers.

Mr. Foster's last,—as it is generally hoped,—the Custom House, is also nearly completed. K. C.

St. Helen's.—A Town Hall is proposed to be built in the market-place of St. Helen's; designs for which were advertised for. I understand that the Messrs Williams's design was approved and that Mr. Broadbent, likewise of Liverpool, obtained the premium for the second best. K. C

Carlisle.—A Literary Institution is about to be built at Carlisle, the designs for which were also advertised for; the particulars, some of your correspondents there, can perhaps provide. K. C.

FOREIGN INTELLIGENCE.

Paris.—M. Geu, a native of Cologne, has been commissioned to erect a church in the quarter of St. Germain; and as the choice of the style has been left to him self, he has determined in favour of the Gothic, as better adapted than any other to the service of the Catholic religion. Some months, however, will elapse before the building will be commenced. Several architectural undertakings are now in progress; among others, the Marché de la Madeleine

Naples.—The portion of the Royal Palace now rebuilding after the fire, will greatly extend the whole edifice, and form an entirely new façade towards the sea. The King has directed that one of the houses at Pompeii shall be completely restored, decorated, and furnished in every respect according to what has been ascertained on the subject from the discoveries that have from time to time taken place. Such a restoration will exemplify, within a brief compass, the domestic architecture and taste of the ancients far more distinctly than the contents of an entire museum, or of numerous volumes.

Vienna.—The plan for the new Custom House has been approved of by the Emperor; and three million guldens are to be appropriated to the erection of the edifice, which will be on the bank of the Danube, below the Invalid Hospital. It is said the design resembles that of the Custom House at Dublin.

Carlsruhe.—A building for a Picture Gallery has been lately commenced from the designs of Bourath Hubsch, the architect of the new Catholic Church at Bulach; which latter edifice is in the so-called Byzantine style, and has a nave and two side isles.

Mechlin.—The idea of completing the celebrated tower of the Cathedral (348 feet high) has been abandoned, the committee appointed for the purpose having reported that it would be impracticable to carry it up any higher.

Railway from Paris to Versailles.—The works on the right bank of the river, have been commenced along the whole line from Asniers to Montreuil, upon which 3,800 men and 600 horses are actively employed. On the line between St. Germain and Versailles, 400 men are at work.

New Masts for Steamers.—At a late meeting of the Academie des Sciences, a memorial from M. Bechameil, an officer of the navy, was read, describing a new means, invented by himself, of fitting steamers with masts, which may be set up and taken down again in less than two hours. The great object of the invention is to save consumption of fuel when the wind is sufficiently favourable to impel the vessel without the use of her engines; and the masts consist of a great number of short spars, capable of being so well joined together that they are equal in solidity to ordinary masts. It was stated at the meeting that M. Bechameil had obtained authority from the minister of marine to fit out a vessel on this plan, and to make an experimental voyage with it to Rio Janeiro.—*Paris Paper.*

Liege.—A great improvement is on the point of being introduced at Liege. Every street lamp is to have one pane of ground glass with the name of the street painted on it, so as to be equally visible in the daytime or when lighted by gas. Corner lamps to have the names both of the principal and the cross streets.

A remarkable celestial phenomenon was observed at Toulouse, about half-past 9 in the evening of June 25th. The heat had been oppressive throughout the day, and the atmosphere had become opaque, but without any appearance of a storm. In the midst, however, of the obscurity, a streak of fire of a pale ashy colour rose from the horizon, and was lost in the zenith. This continued at regular intervals for about a minute and a half, alternately weak and strong, moving in a southerly direction, and parallel to the magnetic meridian.—*French Paper.*

Edruanedorff.—On the 8th of June, in the morning, the newly erected church steeple of Edruanedorff, 110 feet high, fell down. Unhappily, several persons lost their lives. An inquiry is commenced to discover whether this misfortune is to be ascribed to any negligence.—*German Paper.*

A remarkable land slip, as the Frankfort Journal states, has taken place at Tetschen, in Bohemia, where a surface of eight or ten acres, principally forest land, has sunk and continues to sink from its place, on the side of a mountain. In some spots, the earth has given way only to the extent of a few feet, but in others it has fallen 50 feet, so that the trees have disappeared.

Tobacco and Steam.—The Emperor of Russia has, it seems, imposed a tax upon tobacco which will yield 80,000,000 of rubles, to be applied to the formation of railroads and to the promotion of steam navigation. This, it must be admitted, is judiciously converting one smoke into another.

The Pacha's New Steamer.—A steamer, recently built at the Pacha's dockyard, of 140-horse power, with English engines, has been put under the direction of the Tuscan Consul, who has named her the Generoso. She departed on the 28th of April, on her first trip to Constantinople, under Tuscan colours, and is intended to run between that place and Alexandria direct every twenty days. On the 15th of May she returned to Alexandria, being six days from Constantinople; during her passage she was near catching fire three times. Although the engineers on board this vessel are Englishmen, the rest of the crew are made up of Italians, and others little accustomed to regularity and discipline, and consequently not to be trusted with the navigation of a steamer.—*Malta Gazette.*

Baltimore to Philadelphia.—Passengers are now transported by the new railroad and steam boat line from Baltimore to Philadelphia in six hours and a half.—*Montreal Transcript.*

MISCELLANEA.

Steam Carriage.—The first carriage of the Steam Carriage and Waggon Company (built after the experimental carriage had been proved) will be set to work, we understand, within a month. We have also heard that companies are already forming in France, Belgium, and America, under the most favourable auspices. We look forward with great anxiety to the arrival of the first carriage in London, and shall have pleasure in laying the particulars before our readers.—*Conservative Journal.*

Steam-cabs.—On Friday afternoon, June 22nd, Hyde park presented a more than usually gay appearance in consequence of a crowd of fashionables being assembled to witness the trial of a newly constructed steam cab. Among the many splendid equipages, were observed those of the Dowager Countess of Sutherland, the Marquis of Salisbury, the Marquis of Northampton, the Earl of Winchilsea, the Earl of Warwick, Lord Howick, Lord Holland, and many other distinguished personages. About three o'clock the object of attraction moved forward at a slow pace from the old Foot-guard-barracks, Knightsbridge, and threaded its way through the various vehicles into the park, passing through the centre gate of the triumphal arch, and making, in the open space opposite the statue, several turns within its own length. The vehicle was then propelled with apparent ease for three or four hours round the park, and, from the slight noise it made, the horses passing did not appear to be frightened. The average speed of the cab was about 12 miles an hour. The vehicle was guided by Mr. Hancock, the inventor.—*Standard.*

Stafford's Safety Coach.—On Wednesday the 4th ult. the renewal of the patent for Stafford's safety-coach was discussed before the Lords of the Privy Council. Several beautiful models and drawings of the coach were exhibited, every part of which was minutely examined by Lord Brougham and Lord Lyndhurst. The former noble and learned lord was so interested with the subject as to request the patentee to attend at his lordship's residence, in order to a private exhibition of the invention. Mr. John Alexander Galloway, the engineer, stated that he considered the invention most useful, and that he had closely attended to an experiment which confirmed his opinion as to the impossibility of a coach made upon the patentee's plan upsetting. Lords Brougham and Lyndhurst recalled this witness, and examined him upon many of the details, which he fully explained to their lordship's satisfaction. Mr. Gray, of Earl-street, and several well-known *whips*, and others, spoke to the merits of the patent, and the difficulties which Mr. Stafford had to encounter in working it; after which their lordships ordered that the patent should be renewed for seven years, being the full term.

New Hay Rake.—A new rake has been introduced into this country, which promises to be of material benefit to the farmer during the hay-making season. It is an American invention, and consists of a light beam or stock, nine feet in length, to which are attached rows of teeth, both before and behind. It is drawn over the sward by a horse, and as soon as the interstices between the teeth are filled, the workman in attendance moves a handle, which turns the rake right over, and presents the side which has hitherto been empty. In this manner the hay is deposited in little heaps throughout the field. The principal advantages of the implement are that it vastly economises labour in a very busy season, and at the same time sweeps the field with the greatest nicety.—*Dumfries Courier.*

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 27TH JUNE AND THE 26TH JULY 1838.

NATHAN DEFRIES, of Paddington Street, in the County of Middlesex, Engineer, for "Improvements in Gas Meters."—27th June; 6 months.

JOHN PERRY, of Leicester, in the County of Leicester, Wool Comb Maker, for "Improvements in Combing Wool."—27th June; 6 months.

CHARLES GREEN, of Birmingham, in the County of Warwick, Gold Plater, for "Improvements in the Manufacture of Brass and Copper Tubing."—27th June; 6 months.

DANIEL BECKHAM, of No. 22, Sussex Place, Old Kent Road, in the County of Surrey, Stereotype Founder, for "An Improved mode of obtaining Castings in Gold, Silver, and Albata."—27th June; 6 months.

JAMES ROBINSON, of Huddersfield, in the County of York, Merchant, for "An improved method of producing, by dyeing, various Figures, or Objects of various Colours, in Woollen, Worsted, Cotton, Silk, and other Cloths"—27th June; 6 months.

EDWARD WHITE BENSON, of Birmingham, in the County of Warwick, Manufacturing Chemist, for "Improvements in the Manufacture of Carbonate of Lead."—27th June; 6 months.

RICHARD BADNALL, of Cottin Hall, in the County of Stafford, Gentleman, for "An Improvement in the Manufacture of Carpets and other similar Woven Fabrics, which Improvement is effected by the introduction of a certain Article of Commerce not hitherto so employed or used in such Manufacture."—27th June; 6 months.

GEORGE ROUND, of Birmingham, in the County of Warwick, Lock Filer, and SAMUEL WHITFORD, of the same place, Die Sinker, for "A new and improved method of Manufacturing certain of the parts of Gun and Pistol Locks."—30th June; 6 months.

HARRISON GRAY DYER, of Cavendish Square, Gentleman, and JOHN HEMMING, of Edward Street, Cavendish Square, Gentleman, both in the County of Middlesex, for "Improvements in the Manufacture of Carbonate of Soda."—30th June; 6 months.

AUGUSTUS WILLIAM JOHNSON, of Upper Stamford Street, in the Parish of St. Mary, Lambeth, in the County of Surrey, for "Certain Improvements for preventing the Incrustration of Steam Boilers, or Generators, or Evaporating Vessels."—30th June; 6 months.

MATTHEW UZIELLI, of Fenchurch Street, in the City of London, Merchant, for "Improvements in Locks or Fastenings: communicated by a Foreigner residing Abroad."—30th June; 6 months.

WILLIAM DOBBS, of the Penn Road, Wolverhampton, in the County of Stafford, Brass Founder, for "Improvements in the Construction of Racks and Pulleys for Window Blinds, and other useful purposes."—30th June; 6 months.

GEORGE CARTER, of Lombard Street, in the City of London, Gentleman, for "Improvements in Saw Mills."—2nd July; 6 months.

JOSEPH NEEDHAM TAYLOR, of Red Lion Square, Bloomsbury, in the County of Middlesex, a Captain in her Majesty's Royal Navy, for "A certain method or certain methods of abating or lessening the Mischiefs arising from the shock or force of the Waves of the Ocean, Lakes, or Rivers, and of reducing them to the comparatively harmless state known by the term Broken Water, and thereby preventing the Injury done to, and increasing the durability of Breakwaters, Moleheads, Piers, Fortifications, Lighthouses, Docks, Wharfs, Landing Places, Embankments, Bridges, or Pontoon Bridges; and also of adding to the Security and Defence of Harbours, Roadsteads, Anchorages, and other places exposed to the violent action of the Waves."—4th July; 6 months.

EDWARD DAVY, of Fleet Street, in the City of London, Chemist, for "Improvements in Apparatus for Making Telegraphic Communications or Signals, by means of Electric Currents, parts of such Apparatus being applicable to Obtaining, Regulating, or Measuring Electric Currents for other purposes."—4th July; 6 months.

FREDERICK JOSEPH BURNETT, of St. Mary at-Hill, in the City of London, Ship Insurance Agent, and HIPPOLYTE FRANCOIS, Marquis de BONFFET MONTAUBAN, Colonel of Cavalry, now residing in Sloane Street, Chelsea, in the County of Middlesex, for "Certain Improvements in the Manufacture of Soap."—4th July; 6 months.

HENRY ELKINGTON, of Northfield, in the county of Worcester, Gent., for "Improvements in Engines, to be worked by Steam, Air, or other Fluids."—6th July; 6 months.

CORNELIUS ALFRED JAQUIN, of Huggin Lane, Wood Street, in the City of London, for "Improvements in the Manufacture of Buttons."—7th July; 6 months.

WILLIAM KNIGHT, of the City of Chichester, in the County of Sussex, Ironmonger, for "Improvements in Machinery for raising and forcing Water, and other Fluids."—7th July; 6 months.

GEORGE SALTER, of West Bromwich, in the County of Stafford, Manufacturer, for "Improvements in Apparatus for Weighing."—9th July; 6 months.

CLAUDE SCHROTH, of Leicester Square, in the County of Middlesex, Gentleman, for "An improved Method or Methods of Making or Manufacturing the Tools or Apparatus employed in the process of Pressing or Embossing the Surface of Leather, or other Substances. Communicated by a Foreigner residing Abroad."—9th July; 6 months.

WILLIAM PALMER, of Sutton Street, Clerkenwell, in the County of Middlesex, Manufacturer, for "Improvements in Lamps."—10th July; 6 months.

WILLIAM BARNETT, of Brighton, in the County of Sussex, Iron-Founder, for "Certain Improvements in the Manufacture of Iron."—10th July 6 months.

JOHN THOMAS BETTS, of Smithfield Bars, in the City of London, Rectifier, for "Improvements in the Process of Preparing Spirituous Liquors in the Manufacture of Brandy."—10th July; 6 months.

LOUIS CYPRIEN CALLETT, late of New York, in the United States of America, but now residing in Manchester, in the County of Lancaster, Merchant, for "Certain Improvements in Machinery or Apparatus for producing Motive Power, applicable to Propelling Boats and other Vessels, Carriages, Machines, and other useful Purposes. Communicated by a Foreigner residing Abroad."—11th July; 6 months.

HENRY VAN WART, of Birmingham, in the County of Warwick, Merchant, and SAMUEL ASPINWALL GODDARD, of the same place, Merchant, for "Improvements in Machinery or Apparatus applicable to Locomotion on Railroads, and to Steam Navigation, parts of which Improvements are also applicable to Land or Stationary Engines."—11th July; 6 months.

JOHN BETHELL, of Mecklenburgh Square, in the Parish of St. Pancras and County of Middlesex, Gentleman, for "Improvements in rendering Wood, Cork, Leather, Woven and Felted Fabrics, Ropes and Cordage, Stone and Plaster, or Compositions, either more durable, less pervious to Water, or less inflammable, as may be required, for various useful Purposes."—11th July; 6 months.

JOB CUTLER, of Lady Poole Lane, Sparkbrook, in the Parish of Aston, in the Borough of Birmingham, in the County of Warwick, Gentleman, and THOMAS GREGORY HANCOCK, Machinist, of Princes Street, in the Borough of Birmingham aforesaid, for "An improved Method of Condensing the Steam in Steam Engines, and supplying their Boilers with Water thereby formed."—12th July; 6 months.

JOSEPH BENNETT, of Tinnley, near Glossop, in the County of Derby, Cotton Spinner, for "Improvements in Machinery for Carding Wool, Cotton, Flax, or other Fibrous Substances which are or may be carded; part of which Improvements are also applicable to Machinery for drawing, doubling, and roving and spinning such Fibrous Substances as are or may be subjected to those operations."—12th July; 6 months.

JAMES MILNE, of Edinburgh, Gas Meter Manufacturer, for "Improvements in Apparatus employed in transmitting Gas for the purposes of Light and Heat."—13th July; 6 months.

ALEXANDER COCHRANE, of Arundel Street, Strand, in the County of Middlesex, Gentleman, for "Improvements in Umbrellas and Parasols."—13th July; 6 months.

THOMAS ROBERT SEWELL, of Carrington, in the County of Nottingham, Lace Manufacturer, for "Improvements in Manufacturing White Lead."—14th July; 6 months.

RICHARD MARCH HOE, late of New York, in the United States of America, but now residing at 66, Chancery Lane, in the County of Middlesex, Civil Engineer, for "A new or improved Instrument or Apparatus for ascertaining or determining the Latitude and Longitude of any Place, or the Situation of Ships or other Vessels at Sea, and the Dip and Variation of the Magnetic Needle; which new or improved Instrument he intends to denominate 'Sherwood's Magnetic Geometer.' Communicated by a Foreigner residing Abroad."—18th July; 6 months.

HENRY ROSS, of Leicester, Worsted Manufacturer, for "Improvements in Machinery for Combing and Drawing Wool, and certain descriptions of Hair."—18th July, 6 months.

HENRY BRIDGE COWELL, of Lower Street, Islington, in the County of Middlesex, Ironmonger, for "An improved Apparatus answering the purpose of a Press, for retaining and keeping Leaves or pieces of Paper or Cloth; or of other thin Substances, folded or unfolded, in a flattened Condition, under a gentle Pressure."—18th July; 6 months.

JOHN ROBERTSON, of Great Chartlotte Street, Buckingham Gate, in the County of Middlesex, Gent., for "Improvements in Architecture, in its Forms and Combinations, and also in the superficial Figures which may be employed; also for an Improvement or Improvements in the Surfaces of Buildings."—18th July; 6 months.

RICHARD TREFFRY, of Manchester, in the County of Lancaster, Chemist, for "Certain Improvements in the Method of Preserving certain Animal and Vegetable Substances from decay; and also in the Apparatus for, and mode of Impregnating Substances to be preserved."—23rd July; 6 months.

GEORGE RICHARDS ELKINGTON, and OGLETHORPE WAKELIN BARRATT, of Birmingham, in the County of Warwick, Manufacturers, for "Improvements in the coating and colouring certain Metals."—24th July; 6 months.

JOSEPH PRICE, of the Parish of Gateshead, in the County of Durham, Flint Glass Manufacturer, for "Certain Improvements in constructing and adopting Boilers for Marine, Stationary, and Locomotive Engines, and in adapting and applying Boilers to Steam Vessels."—26th July; 6 months.

CHARLES WYE WILLIAMS, of Liverpool, in the County Palatine of Lancaster, Gent., for "Certain Improvements in the means of preparing the Vegetable material Peat-moss or Bog, so as to render it applicable to several useful Purposes, and particularly for Fuel."—26th July; 6 months.

JOHN GRAY, of Liverpool, in the County of Lancaster, Engineer, for "Certain Improvements in Steam Engines, and Apparatus connected therewith; which Improvements are particularly applicable to Marine Engines, for propelling Boats and Vessels, and Part or Parts of which Improvements are also applicable to Locomotive or Stationary Steam Engines, and other Purposes."—26th July; 6 months.

WILLIAM MADELEY, of Manchester, in the County of Lancaster, Machinist, for "Certain Additions to, and Improvements in, Machinery used for Spinning and forming into Cops upon Spindles, Cotton and other Fibrous Materials of the like Nature."—26th July; 6 months.

SIR WILLIAM BURNETT, Knight, Commander of the Royal Hanoverian Guelphic Order, of Somerset House, in the County of Middlesex, for "Improvements in Preserving Wood and other Vegetable Matters from decay."—26th July; 6 months.

ALEXANDER EROLL, of Greenwich, in the County of Kent, Manufacturing Chemist, for "Improvements in the Manufacture of Gas for the Purpose of affording Light."—26th July; 6 months.

FREDERIC EDOUARD FROISSINET, of Covent Garden Square, in the City of Westminster, for "Certain Improvements in the Machinery for Propelling Vessels by Steam, by which their Speed will be much accelerated, with a diminished Power and with a diminished Action in the Water. Communicated by a Foreigner residing Abroad."—26th July; 6 months.

NOTICES TO CORRESPONDENTS.

Several communications came too late for insertion in our present number; we shall give them early attention. We beg to remind our Correspondents that "*Communications should be sent on or before the 25th instant*;" if accompanied with drawings, they should be considerably earlier. We have however to postpone a communication from K. C. for which we have not this excuse; but can only say that our matter has swelled beyond our limits. It would be a great convenience to Journalists if among the many modern applications of Indian rubber some ingenious artist would invent a "patent elastic caoutchouc paper," which should expand as matter flows in, towards the end of the month. In default of such a resource, we have for once been obliged to devote our whole space to matter, omitting our usual two pages of advertisements.

COLE AND TAYLOR, PRINTERS, CRANE-COURT, FLEET-STREET.

REMARKS ON THE IRISH RAILWAY COMMISSIONERS' REPORT.

(Accompanied by a Map.)

We give a small map accurately traced with the railways proposed by the Irish Railway Commissioners, and also by the different capitalists and joint-stock companies, to afford facilities to whom, in judging of the most advantageous mode in which investments in railways can be made, the commission was really appointed. The railways proposed by the commissioners are indicated by dotted lines, and the companies' railways are shown in continuous black lines.

References to Map.

1—Ulster Railway, now in progress, Armagh to Belfast.
2—Cave-Hill Railway, ditto.
3—Belfast and Carrickfergus Railway, to Larne Harbour; and to communicate with Scotland by steam-vessels.
4—Hollywood Railway, surveyed.
5—Proposed Railway, surveyed, Armagh to Port Rush.
6—Line of the Dublin and Armagh Railway Company, surveyed.
7—Proposed Coast Line, recommended by the Irish Railway Commissioners.
8—Proposed Railway, by the Commissioners.
9—Drogheda Railway, Coast Line; act obtained.
10—Dublin and Kingstown Railway, finished.
11—Proposed extension to Bray, recommended by the Commissioners.
12—Dublin and Kilkenny, act obtained.
13—Dublin to Mullingar, surveyed.
14—Proposed Line to Sligo.
15—Ditto ditto to Galway, surveyed.
16—Ditto ditto to Castlebar and Westport.
17—Dublin to Limerick, surveyed.
18—Dublin to Limerick, proposed by the Commissioners.
19—Limerick to Waterford, act expired.
20—Dublin to Cork, recommended by the Commissioners.
21—Ditto to Berehaven, ditto ditto.
22—Proposed Railway to Valentia.
23—Branch Line to Kilkenny, proposed by the Commissioners.
24—Proposed extension from Kilkenny to Waterford.
25—Ditto ditto to Wexford, from Carlow.
26—Ditto ditto from Dundalk to Cavan.
27—Ditto ditto from Drogheda to Navan and Longford.
28—Ditto ditto from Limerick to Ennis.
29—Ditto ditto from Dublin to Blacksod and Broadhaven.
30—Ditto ditto from Enniskillen to Londonderry, surveyed.
31—Proposed Railway from Dublin to Enniskillen, recommended by the Commissioners.

It appears by the map, that the commissioners give from Dublin to the North of Ireland two lines—one along the coast they permit, and another line inland they particularly recommend—the two run nearly parallel with each other. The act for the former has been obtained by private interest—the authority for the latter is included by the commissioners in their scheme of a general railway law for all Ireland. We venture to predict that one or other of these lines must prove a failure, because it is utterly impossible that the trade of Ireland, however extended it may hereafter become, can suffice at present to keep up two such railways running so close and so parallel to each other. This is a case quite analogous to the unfortunate projects of the Grand and Royal Canals, which cross Ireland nearly parallel with each other, and upon the ruinous senselessness of which the commissioners animadvert in a manner no less pointed than just. On what grounds of reason these gentlemen, after condemning parallel lines of canal, could countenance two such lines of parallel railway, does not appear. Their inconsistency in this respect becomes the more apparent, when we find them insisting in another page upon the abandonment of the Dublin and Kilkenny Railway, because it runs parallel with the one they favour. We feel quite satisfied that no body of disinterested and impartial engineers would recommend two such projects. Can there be any foundation for the rumour that the fact of Mr. Pierce Mahony being solicitor to the Northern Coast Railway, has been quite enough to ensure to it the patronage of the commission? This is a question of some seriousness. Mr. Pierce Mahony's name has been associated with that commission in a very strange way; and it is not a little curious that although the commissioners repudiate the Dublin and Kilkenny Railway, they incline most graciously to a parallel line coastways from Dublin to Wexford, which has long been a pet project of Mr. Mahony's. To return however to the question more immediately before us. The company's entire line from Dublin to the North of Ireland, it is easy to show, would effect all the principal objects that the Irish Commissioners' two parallel railways could achieve. The company's line is sufficiently inland to embrace the whole of the interior central trade of the North; while on the other hand, it is convenient enough to afford short branch lines of railways to the respective towns situated on the very margin of the coast; thus thoroughly embracing every desirable object required by the country. How it then could have entered into the heads of any body of men—pretending we will not say to competent judgment, but even to common sense—to recommend two lines of railway running parallel to each other when one line of railway would effect all the objects required, is a mystery which we are quite unable to solve. Were the commissioners less gentlemen of rank and character than they really are, we should not hesitate to account for the thing by supposing some bias or partiality to exist; which is totally inconsistent with the performance of those duties intrusted to them by the government of the country, and that true independence which never fails to uphold those who are really qualified, when employed by their country to decide upon questions of the highest public importance.

This case is so plain and so simple when viewed on the map, that men, the most humbly-gifted with scientific or statistical information upon the subject, will at a glance see the very erroneous conclusion the Irish Railway Commissioners have arrived at, in thus recommending the execution of two parallel lines of railway from Dublin to the North of Ireland—the one to be made by government, and the other attempted, but not begun, by Mr. Pierce Mahony: the short result of all which would be just this—that nearly 100 miles of additional railway will be required to be made, and more than one million sterling to be unprofitably spent.

One objection taken to the inland company, is the expense of crossing the Boyne. As to that however we have to observe, that the company's line approaches at this point to within a short distance of the town of Drogheda; and that it is much less expensive to embank and bridge over the Boyne valley and river, than to make two lines of railway parallel with each other for a distance of nearly one hundred miles. When these gentlemen dwelt upon the expense of crossing the river Boyne, they doubtless forgot altogether some rather bold feats of a like kind, which are included in Mr. Mahony's coast line, which crosses not a river merely but whole bays, as for instance, those of Rush, Malahide, and Dublin. Then as to the statement that the company's inland line is not so good as the more inland one proposed by the commissioners; we apprehend that this is merely an hypothesis which can only be decided before a competent and impartial tribunal, by the evidence of experienced practical engineers. There is Mr. Rastrick for instance, who has surveyed several lines for the North of Ireland;—we should like to see such an engineer as that, called to disprove the assertion that the company's line, the line we are now speaking of, is the best as an engineer's project, and also the cheapest, and quite sufficient to answer all the purposes of passenger traffic and commerce, which the two parallel lines of railway, recommended by the Irish commission, could possibly accomplish; and which, as we have already observed, would save the making of near one hundred miles of parallel railway, or the unprofitable application of one million of money. We therefore invite public attention to these two recommendations of the Irish commissioners; confidently anticipating that the slightest examination of the maps and reports will convince all persons who will take the trouble to open their eyes and look at the lines, as delineated under this royal authority, how gross and palpable has been the blunder here committed. From their failure in this instance, we leave the reader to judge of their fitness to perform the important duties entrusted to them by the executive of the country,—duties, the nature and results of which were thus explicitly set before them in the Treasury minute, immediately consequent upon the issuing of the commission. "The main benefits to be obtained, appear to my Lords to be the impartial and authoritative information which may thus be laid before parliament, and which will aid the legislature in deciding between rival and conflicting interests,—the tendency which it will have of preventing ruinous competitions, and the losses and expenses of litigations before committees,—and the facilities which may be afforded to capitalists and to companies, to judge of the most advantageous mode in which investments in railroads can be made."

"My Lords have full confidence, from the character of the gentlemen appointed to form the commission, that their inquiries will be conducted in a satisfactory manner."—*Treasury Minute*, dated 3rd November, 1836.

From this rapid view of the proceedings of the railway commissioners in the North of Ireland, let us turn to look at another portion of their labours in the South and West of Ireland. We have seen how the anticipations of the Lords of the Treasury have been realized as to the North, let us seek to discover whether they have been more faithfully borne out in the South; because to us it is evident that the engineering projects proposed for the North by the railway commissioners, are not such as to give satisfaction,—not such as are at all worthy of either the confidence or approbation of the public; notwithstanding "my Lords had full confidence from the character of the gentlemen appointed to form the commission, that their inquiries would be conducted in a satisfactory manner."

It appears, on examining the maps and sections, that the distance from Dublin to Limerick, by the line proposed by the commissioners (dotted) is in length 128 miles 4 furlongs, and that of the company about 111 miles—difference 17 miles 4 furlongs in favour of the company's line. The commissioners' line, moreover, does not appear to pass through any of the large towns lying in the route between Dublin and Limerick, and so far it is on another account highly objectionable. Again, the characteristic gradient on the commissioners' line is 1 in 180, while that on the company's line is 1 in 330. So that the difference between the two lines is, first, that the company's line is 17 miles 4 furlongs shorter than that of the commissioners;—secondly, it passes through or close to all the large populous towns lying between Dublin and Limerick, while the commissioners' line passes through none of them, but traverses instead a country greatly inferior in soil and population;—and, thirdly, the characteristic gradient on the commissioners' line is 1 in 180, while on the company's line it is 1 in 330. The facts here stated, suffice to prove that the line proposed by the railway commissioners is inferior in every respect as compared to the line proposed by private enterprise; and therefore again the anticipations of their Lordships are unfortunately not realized even in the South.

The Railway Commissioners, by way of excuse for making their Dublin and Limerick line 17 miles 4 furlongs longer than the company's line, and getting inferior gradients, state that they have avoided the great expense of crossing the Shannon twice. Now what would the expense in question amount to? Two timber bridges could easily be constructed over the Shannon for 4,000*l*. each; and 8,000*l*., we are thus able to show, would cover the whole expense, for the ground is favourable for piles, and timber can be conveniently procured. We are bound to add, that it is not with a very good grace indeed that the commissioners complain of the expense of crossing the Shannon twice, or of any other expense; for what are their favoured enterprises in this way? Let the bridge work proposed by them in crossing Bantry Bay attest their practical wisdom, and command the admiration of a bold age of daring novelty. Where there is a depth of more than 60 feet of water, and a length of more than 500 or 600 yards, they have planned a stupendous bridge work 60 feet deep in the roaring sea, which is to be executed by the diving-bell. There are to be in one part of it alone, fourteen arches in a length of 400 yards, built in 60 feet of sea water, and to be 100 feet high from the bottom to the top. What is the crossing of the Boyne or the Shannon to this diving-bell construction, which requires to be built so deep in water, and is exposed to all the swell and run of the vast Atlantic Ocean? What is the Kingstown Railway sea-wall, which the tide annually demolishes, compared to this work, or any other on the shores of the empire? Why in truth one might as reasonably institute a comparison between the size of a blow-fly and the bulk of the Chimborazo Mountain. Yet are these experienced and practical engineers, the Irish Railway Commissioners, timid men, to cry out "Oh, the great expense of crossing the Shannon twice! Oh, the great expense of crossing the Boyne!" We grant that there is expense in such crossings, but what is the gain? Why a certain saving of more than 17 miles of railway. Surely that is an equivalent. But supposing, for the sake of discussion, just the reverse; what can it be when put in juxta-position with the Brobdignag project of the marine bridge of Bantry Bay, built in 60 feet depth of sea. That, we will venture to say, is a work which no practical engineer in the empire would recommend; and least of all would such a mode of construction as these commissioners approve, receive the sanction of a Smeaton, a Rennie, or a Walker.

Hard as we have already pressed these commissioners, a sense of duty we fear will compel us to press them harder still upon the next important branch of their system we have to discuss—the Dublin and Kilkenny Railway.

There is, we apprehend, but one restriction to which private enterprise should be subjected in the choice of railway lines, either in Ireland or in England; and it is this—no company ought to be permitted so to take possession of any line, as to prevent the further extension of it; and every internal line formed ought to be capable of such extension. This was the principle proceeded upon by the promoters of the company called the Great Leinster and Munster Railway, and the first extension of which is from Dublin to Kilkenny; and it is further worthy of particular remark, that their lines were planned more than three years ago, upon precisely such a general system as the commissioners are so favourable to. We cannot therefore conceal from ourselves that, in deciding against the Dublin and Kilkenny line, the commissioners are to a great extent deciding in the teeth of their own principles. We are assured that the utmost information respecting this railway was given to the commissioners; that the passage of the bill through Parliament was delayed in order to await their report, which was promised in May 1837; and that during a whole year not one word against the propriety or merits of the undertaking was intimated. When, however, the act had been read a second time in the House of Lords, it seems that the Government was told that it ought not to be allowed to pass, as the line in question would interfere with the plans of the commissioners; nevertheless the Government upon looking into the subject, felt the impropriety of preventing a large body of capitalists from executing a valuable public work, and the measure passed both houses, with certain clauses proposed by the Government for the purpose of limiting the progress of the undertaking for one year. This was a provision to give the commissioners full time to bring forward a case against the company. Have they done so? They permitted the year to expire: they allowed the company to acquire the fullest legal title to the line: and after that, they publish a report condemnatory of its execution. Thus what they were not strong enough in fact and reasoning to prevent, they have sought to damage and retard, by the expression of the most injurious, but in our view, the most unfounded opinions.

The report itself is evidently intended to be adverse to the Dublin and Kilkenny Company, and in humble conformity with all the suggestions of Mr. Vignoles, the engineer to an opposing undertaking. Yet might the directors of the Dublin and Kilkenny line refer to nothing better than that report for the most decisive evidence in their favour; for the report proves that while the districts traversed are such as will yield a profitable return to the capitalist, the routes proposed are such as will bring Cork, Limerick, and Waterford nearer to the metropolis than any other, and at the cost of making of as small an extent of railway.

The commissioners stated in their first report, and repeat in the present one—"That a line should be chosen in which the joint traffic of many places and districts should be made to pass to a great extent over a common line." In conformity with this very proper view, they express their object in proposing a system of railways for Ireland, to be—"to conduct the main lines through the counties where trade is most active and extensive." In order to carry out this principle, numerous returns have been obtained, the results of which are thus stated:—"That the largest stream is from Dublin to Naas, where it divides into three branches—the one by Carlow, Kilkenny, and Clonmel, to Cork; the other by Mountrath, Roscrea, and Nenagh, to Limerick; and the third, passing along the Grand Canal, is chiefly dissipated among the small towns on its banks, a small portion reaching Ballinasloe."

We think the commissioners ought to have perceived that it was precisely such opinions and facts as those here referred to, as being entertained by themselves, which must have guided the directors of the Great Leinster and Munster Railway in planning *their* system; for they occupy one of the above three great channels—namely, that to Naas, and thence by Athy and Carlow to Kilkenny, where their terminus is so placed as to be capable of easy extension to Cork by the shortest route (within four miles) near Cahir, which can be adopted. Striking, on the other hand, is the contradiction of the commissioners, who condemn this line, founded on their own views, and who have laid down a main line in opposition to it, which scarcely avails for Naas, and which does not pursue any one of those channels of intercourse which they have ascertained to be followed. They adopt the road to Cork by way of Cashel, a road of little traffic, and upon which only one coach (a mail) runs.

The two lines, that of the company and that of the commissioners, may be considered to diverge from each other at Sallens. Let us then look to the returns supplied by the report itself, to find the relative importance of the districts traversed as exemplified by the Post-office income of the different towns upon the Kilkenny line, 75 miles long, as compared with the first 90 miles of the other line.

Commissioners' Line.	£.	Company's Line.	£.
Rathangan	206	Naas	647
Monasterevan	256	Kilkullen	402
Portarlington	428	Athy	519
Mount Mellick	586	Carlow	1,441
Maryborough	436	Leighlin Bridge	341
Mountrath	444	Bagnalstown	388
Borris in Ossory	160	Goresbridge	366
Thurles	559	Kilkenny	2,112
	3,075		6,216

So far it appears that the proposed main trunk is *not* laid through those districts where "trade is most active and extensive."

Thinking that it might be worth the reader's while to learn the opinions expressed by the commissioners in reference to this line, and their objections entertained against it as a trunk, we propose to quote a passage or two: the grounds upon which private enterprise is to be checked, and existing rights invaded, will thus become apparent. The commissioners admit that the Dublin and Kilkenny line has been laid out with great judgment, and that its gradients are very favourable, but they strongly object to it as the main trunk line for the following reasons:—

"First, as a line to Cork, it is four miles longer to Cahir (a common point) than that by Maryborough; secondly, the communication from the city of Limerick to Dublin by any connexion with it, except by a branch line diverging at a short distance from Dublin, is quite out of the question."

These are the *only* grounds upon which the strong objections of the commissioners rest; and it is for the sake of these alone, that they are prepared to stop the influx of a very large capital into Leinster, and to violate privileges upon which an incorporated company has expended thousands of pounds. Such being the sum of their objections, it will hardly be supposed, that in the very next page but one, they confess that a branch from the Kilkenny line from Ballysax (29 miles from Dublin) will bring Limerick 12 miles nearer to Dublin than the branch proposed by themselves. They go on to say, "we are at the same time fully alive to the importance of a direct railway communication through the rich and populous valley of the Barrow, which contains the towns of Athy, Carlow, Bagnalstown, and Leighlin Bridge, and which would greatly facilitate the intercourse between the city of Dublin and the South-Eastern portion of the county of Wexford, including the towns of Wexford, Enniscorthy, and Ross." This is direct evidence against themselves, and it increases as we proceed, for the postage of the towns lying *upon* the line of communication through this valley more than doubles the postage of those lying *near* (even with the addition of Thurles), to that proposed by the commissioners. Nor should it be forgotten, that independent of the advantage it holds out to these most important districts, it brings Limerick *twelve* miles nearer, and Waterford *forty-four* miles nearer to Dublin than the commissioners' line—opens up the shortest route (within four miles) to Cork—and affords to Wexford that opportunity of connexion with the metropolis of which by the commissioners' line it would be altogether deprived. And here as well as elsewhere we may properly notice another contradiction:—the striking deficiency in their system, occasioned by the absence of a railway through Carlow, is so apparent, that the commissioners suggest a branch of 45¾ miles in length to supply that want; and yet in another part of their report, they state it as their opinion that Kilkenny and these districts are not of sufficient importance to justify a separate line. Thus they give a line, and also say the line is not justified.

Let us now offer a few remarks upon the subject of outlay. The difference in the cost of lines proposed by the Leinster and Munster Company, and those suggested by the commissioners for the connexion of Limerick, Cork, Waterford, and Kilkenny with Dublin, is thus given. By the commissioners' central system it may be effected by the formation of 265 miles of railway; and by the company's plan, that of the Great Leinster and Munster Railway, by the formation of 286 miles. The difference therefore is twenty miles: and for that, Limerick and Waterford will be brought so much nearer to Dublin; and all the great commercial and productive places, instead of comparatively barren districts, will be directly penetrated. But if to the preceding 265 miles, we add the branch of 45 miles suggested by the commissioners for the valley of the Barrow, instead of their proposed branch of 26 miles to Kilkenny, it is plain that "the system" has not even economy to recommend it.

The commissioners, we fear, attach too much weight to their simple opinion, at least they sometimes pronounce opinions for which the reader is utterly at a loss to supply reasons. Thus they talk of the important local advantages possessed by the main line, recommended by them in preference to the Kilkenny line, which again they deem "inconsistent with the general interests of the country, and directly opposed to those of several extensive and most important districts." Upon passages like these we can only observe that it is impossible to imagine what they can allude to.

The Post-office returns, quoted by themselves, show the relative importance of the districts proposed to be traversed; and the effect of the two lines as main lines is as follows:—

	Commissioners' Line.	Kilkenny Line.
Dublin to Limerick	125 miles.	113 miles.
„ Cork	166 „	170 „
„ Waterford	141 „	97 „
„ Kilkenny	76 „	73 „

Can it be necessary to add another word to those figures?

We now take up another line. The proposed railway from Limerick to Waterford, as described in several very important passages in the body of the report, is stated by the commissioners to pass through the towns of Tipperary, Cahir, and Clonmel, containing populations of 6,972, 3,408, and 18,000. But turning to the Atlas map and sections, we find that it runs 5¼ miles North of Tipperary, three miles North of Cahir, and one of Clonmel. The discrepancy here is so serious, that we find it difficult to suppose it unintentional. There is another circumstance connected with this line, which is rather serious. We have good authority for asserting that a map of this line, as originally projected by Nimmo and amended by Bald, engineers of considerable reputation, was delivered in to the commissioners in November 1836, but the line is *altogether suppressed in the Atlas map*, which professes to show "the lines laid down under the direction of the commissioners, and those proposed by private parties."

Another and a very marked fault in the commissioners' plan for a railway between Limerick and Waterford, which evinces either great ignorance or neglect of local wants, is that it runs half a mile North of the town of Carrick, without at all being connected with the harbour and navigation of the river Suir at that place. It would further appear, that the commissioners made no survey from Carrick to Waterford, either on the Eastern or Western side of the Suir, although in a plan upon which one would least expect to find them, they have given proposed rail lines on both sides of that river from Carrick to Waterford, but without any sections; the Eastern line copied from Nimmo's survey, and the Western copied, as we have reason to know, from the very document given in by the Waterford and Limerick Railway Company, which they have so strangely excluded from the Atlas map, and which, where obscurely described, they assert to have been "a railway as proposed by George Stephenson, Esq., civil engineer, about 1830." A more incorrect assertion than this last never was made. George Stephenson's report on the Waterford and Limerick Railway is now before us, and he proposes nothing of the sort. Neither does he in any one part of his report allude to any line of railway suggested by him or any other person to cross the Suir at Carrick, and run along the South-Western side of that river down to Waterford. This original idea is solely due to the recent promoters of the Limerick and Waterford Railway, under the title of the Suir and Shannon Junction Railway.

In the first place then, the survey made of the Limerick and Waterford Railway by the railway commissioners is incomplete; and in the second place, it carries the impress of being a very erroneous and inaccurate delineation, as shown by the following statement:—

In Part 1, Plan 4, 5, and Part 1, No. 11—Limerick to Waterford.

	M.	F.	C.
By the measurement on the maps, by the scale going along the line coloured yellow, East side of river Suir, we have	75	2	4
By the measurement figured on the map of the proposed railway, by the railway commissioners	73	0	0
Difference and consequent error	2	2	4
Again—			
A measurement on the maps by the scale gives, going along the line coloured blue, West side of Suir river	76	2	0
Figured length on the map of the proposed railway, by the commissioners	73	0	0
Difference and consequent error	3	2	0

Further, in the sections given of the survey of the Limerick and Waterford proposed railway by the commissioners, at 39 miles from Limerick, marked on the section to be found on map, part 1, plan 4, is a gradient of $\frac{1}{1667}$ for 2¼ miles;—while the heights which terminate

that slope, are marked respectively 278 feet and 307 feet; difference between these numbers 29 feet for 2¼ miles, which would give a gradient of $\frac{1}{400}$, instead of one in 1667, as figured on the section; (for $\frac{5280 \times 2\frac{1}{4}}{29}$ equal to 1 in 400). Again, the section states 3 feet 2¼ inches per mile, for 2¼ miles would give a difference of level of 7.0268 feet (for 3.194×2.2=7.0268); while the vertical heights on the same section, figured 278 and 307, would give a difference of level of 29 feet. Here is consequently another error in the levels, of 22 feet. We beg the commissioners' attention to these very gross errors both in the linear measurements and levels, affecting not only the character of the whole of their surveys, but involving more deeply that of the professional men whose names are appended to their maps and sections. Any person who knows a little arithmetic and the use of a pair of compasses, may in a few minutes detect these blunders; which are quite sufficient, we repeat, to ruin the character and reputation of the work. We beg to observe that plans and sections so defective, would be thrown out most unceremoniously by any committee of the House of Commons. Yet we have the Morning Chronicle and the Sun newspapers praising to the skies this work of the Irish Railway Commissioners. Good confiding Editors! How well-founded and trustworthy are the praises they bestow. These, we have further to observe, are only a few of the numerous errors which those who are competent to the task may detect with facility, both in the maps, sections, and levels of the commissioners' proposed railways through Ireland, executed under the authority of a royal commission. Nevertheless "my Lords have full confidence, from the character of the gentlemen appointed to form the commission, that their inquiries will be conducted in a satisfactory manner."

We have only one more remark to make upon the Waterford and Limerick Railway. The company's line was surveyed and reported on in the most favourable terms by Telford, George Stephenson, and Bald. Those gentlemen entered into a minute estimate of the cost and profits of the line as projected by Nimmo, and they calculated the returns at 12 per cent. The commissioners however set the line aside, and substitute another, the profit on which they estimate at two per cent.!

Thus far we have seen that the system of the commissioners gives one main line of railway to traverse the Southern part of Ireland, with proposed branches, and a corresponding one to the North and North-Western parts; but much of the centre of the island and the whole of the province of Connaught has been left without any line whatever. The great province of Connaught, or the fourth part of Ireland, has not been deemed worthy of having one single mile of railway present or future planned through it. The South and South-Western, and the North and North-Western, are the only favoured parts; but the great central and Western portions of the country, are abandoned to the very imperfect modes of intercommunication already existing, although private enterprise offers to complete more than one extended line. Now the province of Connaught is one of the most fertile, fruitful, and populous districts in Ireland; one too, much more capable of extended improvement than the sterile rubbish of the rocky mountains and transition slate districts of the remote parts of Kerry and Cork, which are patronised not for one only, but two most costly lines by the commissioners; which, moreover, as they themselves confess, will not pay. Is it not surprising, is it not most unreasonable, that the wild mountainous districts of the South of Ireland should be preferred to the magnificent, fertile regions of the great limestone districts of the centre West, so very much more abounding in profitable and improvable resources? The Western shores of Connaught are everywhere surrounded with fishing banks, on which are to be found an abundance of all kinds of fish, such as cod and ling. The fishing banks off Bofin Island and Achil Island; the fine harbours of Balinakill, Blacksod, and Broadhaven, present mines of inexhaustible wealth, and facilities for carrying on the deep sea fishery to a greater extent and with a richer success than does any other portion of the shores of the empire. If we look at these sources of maritime greatness, so easily convertible into great stores of national wealth; if we look at the fruitful limestone plains of Connaught, producing grain of all kinds in the greatest abundance, and in this respect possessing the especial qualities which the commissioners themselves describe as being the standard inducements for the construction of railways; if we look at the innumerable herds of cattle which are annually marketed at Ballinasloe, the largest cattle fair in Ireland; if we look at the positive richness of Connaught in fish, in grain of all kinds, in cattle, and in an extremely fertile soil,—we are left no room to doubt the fitness, nay more, the necessity of recommending to the inhabitants of so large and so valuable a district a railway to transmit the immense productions of her soil, and to carry back the imports which her population must consume.

To one point we must here request particular attention. Connaught is so peculiarly situated, that it requires a most difficult and dangerous navigation to sail from her shores with agricultural produce for the English market, either Southwards round Cape Clear, or Northwards by the Northern Channel. If a merchant vessel takes the voyage Northwards to Liverpool, she sails about 500 miles; if Southwards to Liverpool, 850 miles; while the distance across Ireland from the centre of Connaught to Liverpool is not more than 240 miles. This short statement shows clearly the great advantages a railroad running through the centre of Connaught to Dublin must confer, for it would provide the most direct and quickest transit for all kinds of commodities to the first market in the world. Such being the fact, we shall be anxious to learn the grounds upon which Government can propose to support a system which must have the effect of throwing back in the scale of improvement and civilization one of the richest quarters of Ireland, while a liberal share of the advantages of railway communication is proposed to be extended to all the other parts of the island. Something much stronger, we apprehend, and more sensible, will be required under this head of the inquiry, than the double and very imperfect plea put in by the commissioners when they assert, that the Grand and Royal Canals will be ruined if a railway passes through the centre of Ireland and Connaught, and that these canals are quite sufficient to answer all the traffic which Connaught requires. For in the first place, the commissioners ought not to have forgotten that there are only twelve miles of a canal in all Connaught; and in the next place, that there happens to be the finest river and canal navigation in all Ireland, running from Dublin to Limerick, nearly parallel with the line of railway which they insist upon giving to the country between those two cities. Then again, we have the Barrow navigation parallel on the other side; and in the North we find the Ulster canal, the Lagan canal, the Newry canal, and the Boyne navigation, all close to and competing with the commissioners' railway for that part of Ireland. From this embarrassment these Royal Commissioners, we think, will find it difficult to relieve their system; for what can be more monstrous than to intimate, as they do, that the various railways they have laid out and recommended for the South and North of Ireland will not injure the numerous canals and river navigation in those districts, while a single line of railway straight through the province of Connaught, in which there are only twelve miles of inland navigation, must utterly destroy the Grand and Royal Canals, which are not in Connaught at all? Again, we should be glad to know why a line has not been given from Ballinasloe, where the canal terminates, to Castlebar and Galway? The country is quite favourable, and entirely limestone, so much approved by the commissioners. Pray, has the Manchester and Liverpool Railway destroyed the traffic of the Duke of Bridgewater's Canal between Liverpool and Manchester? On the contrary, does not the canal carry more goods now, than it did before the railway was made? We go farther, and lay it down as a broad and incontrovertible principle, that by whatever means a country improves her industry, increases her trade, and augments her capital, her navigable rivers, navigable lakes, and still-water canal navigation, must also partake of the general progress of commerce and intercommunication.

In winding up these observations, we feel it necessary to observe that we have only written them after a full consideration of the subject in its various details and bearings, with a most sincere desire for the good of Ireland, with the best regard for the railway interest of the empire generally, and with no feelings personally unfriendly in the smallest degree to the commissioners. Having given in a former number a list of the railway companies in course of formation in Ireland when the commission was appointed; and having shown that the great object contemplated by Parliament and the Government in permitting the commission to issue, was the aid and facilitation of the enterprises designed by those very bodies; we have left the reader no room to doubt or dispute the final conclusion to which we have led him, and which affirms that the commission has proved a signal and total failure,—that it never will be acted upon,—or that if such an attempt be made, the most ruinous consequences must follow. The compliments which have been so freely lavished upon the commissioners by some of the ministerial papers, and the acknowledgments which have been tendered for the statistical information combined in the report, are altogether beside the real question at issue; for the estimates furnished by the various companies which the report attempts to put down, would have gone near to give us the same knowledge, and very nearly to the same extent and in the same degree. As it is, the inquiries of the commissioners are not available for the most obvious uses. For Parliamentary proceedings it will be impossible to rely upon them, because

they have been thrown into new and arbitrary forms, with the view of illustrating the commissioners' system, instead of furnishing, according to the prescribed usages of either house, the proper means of applying to the different lines the evidence indispensably required to sustain them. As to the main suggestion of the commissioners, the *summum bonum* of the report, and grand finale of the inquiry, it is so palpably weak and mischievous, that we shall not waste a word upon its refutation. We shall content ourselves with announcing the proposition, and leave it to gain friends as it can,—it is that the *making of all railways in Ireland, as proposed by Pierce Mahony, Esq.,* shall be intrusted to only one body of capitalists, who shall be instructed by Government and largely supplied with public money, and that this body in return shall be compelled to make all the suggested lines, good and bad, setting the profits of the one against the losses of the other.* To the jobbers and monopolists who infest the court-yards of Dublin Castle this will doubtless appear a cheering prospect, and wise counsel. By men of good sense, however, who happen to know the world and the value of money, the upshot of this expensive commission will be regarded, we believe, in a very different light, and repudiated with very little respect. For ourselves, we do not see what better step ministers can take in this matter, than to go back to the point all parties stood at in 1836, when the commission issued, and leave the different joint-stock companies to proceed in the usual Parliamentary manner as they shall respectively see fit.

In order to verify what we have said already relative to the errors which prevail throughout the Plans and Sections, we subjoin a statement of such as we have had time to detect.

PART I.—SOUTH OF IRELAND.

	M.	F.	C.
Plans Nos. 1, 2, 3, 4, and 5, the figured length given on the Plans from the Zero of Mileage, near Dublin, to Limerick	125	4	0
The length measured by the scale on the Map from the Zero of Mileage, near Dublin, to Limerick	123	6	0
Difference or error	1	6	0
The figured length on the Plan of Railway from Zero of Mileage, near Dublin, by Limerick to Tarbet	160	0	6
The length of ditto measured by the scale on the Maps	158	0	6
Difference or error	2	0	0
Plans 4, 5, and 11 of the proposed Railway from Limerick to Waterford, measured by the scale along the line coloured yellow, East side of River Suir	75	2	4
The figured length on the Plans of ditto	73	0	0
Difference or error	2	2	4
On the same Plans, measured by the scale along the line coloured blue, West side of River Suir	76	2	0
The figured length on the Plans of ditto	73	0	0
Difference or error	3	2	0

In Plan No. 7 of Railway from Cahir to Mallow, there is a difference of two miles, if measured by the scale, of that portion between the figured distances 128 and 152 miles.

In Plan No. 8 of Railway from Mallow to Cork, and Blarney to Inchy-geelagh, there is a difference of two miles more, in measuring by the scale along the line, and the figured distances of that portion between the figured distances 168 to 195 miles.

In the Index Map, the length from Dublin to Limerick of the proposed Railway measures 120 miles; the figured length on the Plans 1 to 5 from the Dublin Post-office to Limerick is 128½ miles, making a difference of 8½ miles.

The scale on the Index Map is very incorrectly graduated, and also many of the scales attached to the diagram sections;—they vary from 5 to 10 feet.

Section Dublin to Limerick (Plan No. 2, Diagram Section).—A gradient is given on the section, of 1 in 2164 for 4½ miles; the vertical heights terminating this gradient on the section are 255 feet and 256 feet. There must be an error here of 10 feet, for $\left(256 - 255 = 1.\ \frac{5280 \times 4\frac{1}{2}}{1} = 23760\right)$. This would give a gradient of 1 in 23760 feet, and not 1 in 2164, as figured on the section; and even allowing the error of 10 feet, it would not be a gradient of 1 in 2164, but 1 in 2160.

In No. 3 Diagram, Section Dublin to Limerick, there is a gradient of 1 in 7920 for 4¼ miles; the vertical heights terminating this gradient on the section are 409 feet and 406 feet; this would give a gradient of 1 in 7480, and not 1 in 7920, as figured on the section; for $\left(409 - 406 = 3.\ \frac{5280 \times 4\frac{1}{4}}{3}\ 7480\right)$. On the large section, the gradient is figured 1 in 7458, which is also wrong.

There are several other errors in the sections of the proposed Railway from Dublin to Limerick; but enough is here shown to prove how inaccurate and defective they are.

No. 4, Section Limerick to Clonmel. The second last gradient in this section is stated to be 3 feet 2⅓ inches per mile, or 1 in 1667 for 2⅕ miles; the two vertical heights terminating this gradient are 278 feet and 307 feet, this would give a gradient of 1 in 400, and not one in 1667 $\left(307 - 278 = 29.\ \frac{5280 \times 2\frac{1}{5}}{29} = 400\right)$. If it be a rise of 3 feet 2⅓ inches, as stated in the section, the difference of level would be 7 feet ($3.194 \times 2.2 = 7.0268$ feet); now taking the two verticals given on the section, of 278 feet and 307 feet, the difference of level would be 29 feet in place of 7 feet;—this is a most serious error as regards the levels.

No. 5. On the continuation of the same section another error exists, although not of so serious amount as the last. The section states—"This gradient of about 16 feet per mile, or 1 in 330, to be obtained on further examination." The two verticals terminating this gradient on the section are respectively 142 feet and 309 feet; this would give a gradient of 1 in 339.88, $\left(\text{for } 309 - 142 = 167.\ \frac{10.\frac{3}{4} \times 5280}{167} = 339.88\right)$ and not 1 in 330, as figured on the section.

PART II.—NORTH OF IRELAND.

	Miles.	Yards.
Plate 33, Railway from Dublin to Armagh; length figured on the Section	85	880
Measured length by the scale	84	1540
Difference or error	0	1100
Plate 34, Railway from Navan to Enniskillen; the first horizontal distance figured on the Section at Navan is	1	1750
The length, measured by the scale, is	1	750
Difference or error	0	1000
The horizontal length of the terminating gradient on the Section at Enniskillen, measured by the scale, is	2	880
Figured length	1	910
Difference or error	0	1730
Amount of the total figured length on the Section from Navan to Enniskillen	68	415
Amount of detailed length on the Section from Navan to Enniskillen	66	415
Difference or error	2	0

In the Diagram of Clivities there are the following errors:—

	Gradient on small Section.	Gradient on large Section.	Gradient obtained by calculation.
Plate 8. Dublin to Armagh	1 in 2086	2091	2054
Plate 20. Navan to Enniskillen	1 in 736	736	731
"	1 in 4320	4320	4595 and 4628

Diagram Section, from Dublin to Armagh, of maximum gradients not exceeding 1 in 180, there are the following errors. The corrected column contains the gradients calculated by ourselves; by dividing the length by the difference of the height at the extremes of each gradient as marked on the sections.

* It appears clear, after some warm disputing which has only confirmed the charge, that the Report, as just printed, contained rather a significant note at page 93, which has since been suppressed. We give a copy of it, as we saw it in a printed copy of the Report itself; and we shall only observe upon it, that reading in connexion with it the concluding chapter of the Report to which it was appended, there certainly does appear reason to think that the commissioners intended to indicate, to the prejudice of other competitors, the body of capitalists represented by Pierce Mahony, Esq., as those which ought to have the benefit of the monopoly they have recommended.

"So long back as December 1836, a body of capitalists, represented by Pierce Mahony, Esq., after an interview with the chief secretary, communicated to the commissioners a readiness to undertake any lines to the South-West that they should recommend, and offered to contribute 1,000*l.* towards making the necessary survey; and in May last, 1838, they repeated their desire on understanding that the commissioners' report would be very shortly after presented to Parliament.

"They explained the cause of their not having pressed on Parliament any views of their own; as they considered that such proceeding must have tended to embarrass the execution of the propositions that should be made by us.

"This is no doubt true, and we must think that these gentlemen deserve credit for their forbearance.

"We have added the two letters to our appendix."

REVIEWS.

A Practical Treatise on Railroads, and Interior Communication in general: containing numerous Experiments on the Powers of the improved Locomotive Engines; and Tables of the comparative Cost of Conveyance on Canals, Railways, and Turnpike Roads. Third Edition, with additions. By Nicholas Wood, Colliery Viewer, Member of the Institute of Civil Engineers, &c. London: Longman and Co.; 1838.

(Second Notice.)

It is now very generally admitted that Railways must shortly become the great highways of the kingdom; and it consequently becomes an object of national importance, to consider the best modes both of constructing and of working them. It appears to us highly desirable that they should all be governed by one law, that all their regulations should be uniform; which we conceive would save much inconvenience and annoyance to the public. No part of the system assuredly requires more full consideration than the gauge for laying the rails, which in consequence of the unfortunate relinquishment of the standing order of parliament requiring a uniform gauge,—a relinquishment that we lately deplored, and shall not soon cease deploring,—varies at present from 4 ft. 8½ in. to 7 ft. If this system,—or rather, this want of system,—be allowed to continue, and every company be left to adopt its own favourite gauge, we fear that the greatest confusion will overspread the whole, and serious inconvenience be the result to all parties concerned. This will be the most sensibly felt at large towns, such for instance as the Metropolis, where many lines come in from various quarters as to one common centre. In London it seems to be most essential that the various railways should all unite, that they should all be brought more into the heart of the city, and be made also to communicate with the Thames. We are indeed aware that there exists a strong opposition to the introduction of the metropolitan lines any further into town,—especially on the part of the Corporation of London. This powerful body will however probably be convinced ere long of the necessity of such a measure; for if it be not adopted, they will assuredly find many wholesale dealers and merchants removing their warehouses to the vicinity of the various railway termini, in order to save time in the transaction of business, and labour and expense in the carriage of goods. It now occupies, for instance, as much time to go from the Royal Exchange to the terminus of the Great Western Railway, as at the average rate of travelling on that line is proposed to be consumed in steaming from Paddington to Maidenhead.

Regretting as we do, that the opportunity should have been lost of carrying on the railway system from the first on a uniform and consistent plan, we think that much might yet be accomplished towards this very desirable object. For this end we would recommend as a highly advisable measure, the immediate formation of what might be termed a Railway Congress, consisting of one Director and the Engineer of each line. They should meet occasionally for the consideration of such points as may appear of mutual advantage; as the regulation of the traffic, the engines, and the general mode of conducting the business of the lines. Their decision should be binding on all the companies; and when necessary they might recommend to parliament bills for the regulation of railways; which from such a body would come supported by the high authority of extensive and practical experience. We would further suggest the raising of a fund by periodical contributions from each company proportionate to their respective capital, to be at the disposal of the Congress for the purpose of making experiments on subjects of mutual importance, such as the best form of rail, the most advantageous construction of locomotives, passengers' and goods-carriages, signals, &c. For these important purposes, there is at present no proper provision; each company has to form its own experience, except so far as it can avail itself of the experiments of its predecessors. Thus by insulated efforts capital is squandered, which by judicious combination might be accumulating an immense fund of useful experience to the mutual advantage of all the subscribing parties. We throw out these suggestions, merely as hints to excite to further reflection; and we are firmly convinced, whatever be thought of our suggestions, that the subject itself is deserving of the most attentive consideration.

But all this time, Mr. Wood is waiting for our "second notice;" we beg his pardon, and will at once return to the consideration of his book, only reminding him by the way, that it was he who furnished us with the text for our digression.

There are perhaps few branches of practical science that require in the student a more complete and extensive knowledge of the principles of Mechanics and Mathematics, than railway engineering;—so many and various are the circumstances which require to be taken into consideration, and the omission or inaccurate appreciation of which would lead to erroneous and often ruinous results. Of the importance of these branches of knowledge, Mr. Wood seems fully aware; and he has accordingly introduced into his work several valuable algebraical formulæ for the assistance of the engineer in his calculations.

Chapter VI. is entitled *Description of the different kinds of Motive Power used on Railroads, and Disposition of the Road for their application.* It treats first of horses, then of self-acting planes, afterwards of various kinds of planes worked by stationary engines, and lastly of locomotives. Under this last head, which is by far the longest, will be found much interesting information respecting the progressive improvements in the construction of locomotives, detailed accounts of various experiments tried from time to time, and tables of the dimensions &c. of engines manufactured by Messrs. Stephenson, Hawthorn, and others.

The Friction and Resistance of Carriages on Railroads is investigated in chapter VII. This subject was little understood till M. Pambour published to the world the results of his valuable experiments on the Liverpool and Manchester line. Of this information, and of the valuable experience also of several eminent engineers, Mr. Wood has made use in this part of the work. The following table is the result of some experiments made by Mr. George Rennie in 1825, on the friction of axles with different unguents.

TABLE XII.

Insistent weight in lbs.	Resistance in parts of the weight, and kind of unguent employed.				
	Tallow.	Oil.	Hogslard.	Soft Soap.	Anti-attrition.
56	—	$\frac{1}{37}$	$\frac{1}{34}$	$\frac{1}{28}$	—
112	$\frac{1}{33}$	$\frac{1}{33}$	$\frac{1}{36}$	$\frac{1}{32}$	$\frac{1}{14}$
224	$\frac{1}{36}$	$\frac{1}{32}$	$\frac{1}{25}$	$\frac{1}{37}$	$\frac{1}{24}$
336	$\frac{1}{40}$	$\frac{1}{20}$	$\frac{1}{14}$	$\frac{1}{35}$	$\frac{1}{32}$
448	$\frac{1}{40}$	$\frac{1}{18}$	$\frac{1}{16}$	$\frac{1}{35}$	$\frac{1}{33}$
560	$\frac{1}{40}$	$\frac{1}{19}$	$\frac{1}{11}$	$\frac{1}{37}$	$\frac{1}{38}$

The oil and hogslard show, that the maximum effect took place with light insistent weights, gradually diminishing in effect, or showing an increase of resistance, as the insistent weight was increased; while the contrary is

the case, with the more viscid unguents of soft soap, and the anti-attrition mixture.

It would not, perhaps, have been necessary to have gone so much into length on this subject, had not all these experiments proved, that the practical result, as displayed in the modern built carriages, is, that the friction of attrition on their axles is greater than that of other machinery of a like nature. Either the axles and bearings are so proportioned, that with certain insistent weights, a maximum effect is not produced; or, that the unguent employed is of such a nature, as not to prevent the contact of the metals, or that it is more viscid than necessary.

When such large sums are expended, to make the gradients of the lines of railway moderate, it is equally important to diminish the resistance of the carriages, by diminishing the friction.

Coulumb found the friction, with hogslard, one-twenty-seventh of the weight; Tables VI. and VII. show it the sixty-second and sixty-sixth parts; Southern, the fortieth; Mr. Rennie, with tallow, the fortieth, and with oil the thirty-seventh; the experiments, with the common coal waggons, in Table V., the twentieth; the experiments on the Darlington railway, the twenty-first; while the experiments with Mr. Stephenson's carriage, on the Liverpool and Manchester railway, shows it equal to the eleventh part of the weight.

In the two latter cases, the ratio of the diameter of the axles to that of the wheels, was as 12 : 26; therefore, the aggregate resistance is less in the latter than the former; for 21 + 12=252, and 11 + 26=286th part of the weights.

The insistent weight in the former was about 100lbs. per square inch of bearing, and in the latter, more than 250lbs. per square inch; experiment giving 90lbs. per square inch, when the effect is a maximum.

It appears, therefore, that the weight of the carriage, and area of bearing surface on the axles of a carriage, should be such as not to subject the latter to a greater pressure than 90lbs. per square inch; and, having determined this, it then becomes a question, how the axle is to be proportioned, to obtain this pressure.

The experiments made on the single axle, show the effect diminished, about fifty per cent. with the weights, 2465, and 1331, when the length of the bearing is doubled; *as, therefore, the resistance will be increased, in the direct ratio of the increase of the diameter of the axle, and only one half* in the terms of the *length; it appears that, in calculating the size of the axles, to obtain the necessary area of bearing surface, the length should be equal to twice its diameter, and that the area should be such as not to subject it to a greater insistent weight than 90lbs. per square inch.*

Taking the result of the common coal waggon bearings as a standard, it would appear, that in practice, we may calculate on the friction upon the axles, as the twentieth part of the weight, or f'=·05, and making f=·001; we have the force, P, necessary to drag a carriage on a level railway

$$P = \frac{W}{f} + \frac{W'}{f' \frac{d}{D}}$$

The next chapter is devoted to the *Friction of Ropes used by fixed Engines on railroads.*

The ninth chapter, entitled the *Theory and Application of the various kinds of Motive Power used on Railroads,* treats at great length of the various powers before described in chapter VI. Under the head of *fixed engines,* it details the results of several additional experiments. Some errors have crept into the calculations in this chapter, which we recommend to the author's notice, with a view to their correction. Here, as in chapter VI., locomotive engines deservedly claim by far the greatest share of the space allotted to the subject. Mr. Wood has here again availed himself of the valuable experiments of M. Pambour, from whose work he has extracted rather largely; he also makes use of such other experiments as he has been a[ble] to obtain. The construction of locomotives is however still in [its] infancy; it is well known that with the same work one engine will last twice as long as another by the same maker; and so many defects still exist in the machinery, that much more information and much longer experience will be necessary to our attaining to a perfect construction of the engine. The great and increasing demand is daily bringing out improvements, which will no doubt by degrees increase the efficiency, promote the durability, and diminish the cost of the machine. Several important improvements have been adopted within the last two years; and if we are to believe the accounts given by the Americans of their performances in this line, they appear to excel us in the power of engines for ascending inclined planes. Some experiments have been recently published, performed by an engine built by Norris of Philadelphia. The account is given below,* but we should very much like to see it confirmed by some eminent English engineer, as well as the American and Austrian ones whose authority is cited. For if Mr. Norris's engines *really do* what is stated of them, it is most desirable that we should make ourselves acquainted with their construction.

In four following chapters, Mr. Wood has collected some valuable information relative to the comparative cost of different modes of conveyance. After giving various calculations founded on the experience gained on several railways, he brings forward the following results.

Having, therefore, determined the expense of conveyance by locomotive power on railways, both on public railways, for the conveyance of general merchandise, minerals, and passengers; and, likewise, of minerals alone, on public railways, we now give the result in a tabular form, taking the cost on the London and Birmingham railway for the expense of haulage.

TABLE XIV.

Table of the cost of conveyance of goods and passengers by locomotive engines, on railroads.

Rate of speed in miles per hour.	Resistance per ton in lbs.	Cost of haulage per ton per mile.	Cost of carriages per ton per mile.	Cost of conveyance per ton per mile.	Charges for conveyance per ton per mile.	Remarks.
		d	d	d	d	
8	8·5	0·375	0·19	1·065	1·065	Export coals.
					1·566	Landsale coals.
12	8·5	0·5	0·227	2·138	3·5	General merchandise.
20	8·5	0·25 per passenger	0·206	0·675 per passenger	1 to 1½ per passenger	—
		1·73 per ton		2·855 per ton.	12·87 per ton.	—

In this table, a very great difference of cost will be observed, between the conveyance of coals, and general merchandise; the latter amounting to 2·138*d.* per ton, per mile, while the average of the former is 1·315*d.* per ton per mile. This arises from several causes. On public rail ways, for general merchandise and passengers, when the latter are conveyed at a higher rate of speed, it is almost, if not entirely unavoidable, to prevent the trains with goods partaking, to a certain extent, of a rate of speed beyond that of the most economical; the trains are likewise obliged to be set off, at certain stated periods, whether they are fully loaded or not. We see that the trains, with general merchandise, upon the Liverpool and Manchester railway, from which the above cost is deduced, average only 17·2 tons gross load; upon the Stockton and Darlington railway the average load is 63·6 tons, the former travelling at the rate of twelve to fifteen miles an hour, and the latter eight to ten miles an hour. On a reference to § 4, Art. 7, Chap. IX., it will be seen, that the relative economy of these engines travelling at different rates of speed, and with loads proportioned to the rate of speed, is in the ratio of the resistance of the gross load taken, including the engine, the relative resistances of these loads will be as 66 : 83.

---

* "The performances of my engines," says Mr. Norris, "on the inclined plane at the Schuylkill have exceeded the very best performances of the best English engines by *seventy per cent.*, as will be seen on comparison. This plane is 2,807 feet in length; ascent in that distance 196 feet; equal to a grade of 369 feet rise per mile, or one foot rise in 14·3 feet.

1st. July 9, 1836.—The George Washington, weighing 8,700 lbs. on the driving wheels, ascended to the top in 2 minutes 1 second, dragging up a load of 19,200 lbs., and with the same load descended, stopping frequently in the descent, and moving up and down for the space of fifteen minutes.

2d. July 19, 1836.—The same locomotive made another performance in the presence of several scientific gentlemen from the city of New York, who visited Philadelphia for the express purpose of witnessing what they had not believed. Messrs. D. K. Minor and G. C. Schaeffer, the editors of the New York "American Railroad Journal," were present. They came doubting, and on arriving at the foot of the plane, with a large party of Philadelphians, they still doubted the practicability of overcoming so steep an elevation. Anxiety was on every face—a bolder attempt had never been made. A load of 31,270 lbs. was then attached, consisting of the tender with fuel and water, two passenger cars, and 53 passengers. The engine was started at the base, and reached the summit in 2 minutes 84 (?) seconds. I quote the editor's own words:—'The enthusiasm of feeling manifested cannot be described; so complete a triumph had never been obtained. The doubts that had been entertained by some, and the fears of others, were dispelled in an instant. The eager look that settled upon every one's face gave way to that of confident success, while all present expressed their gratification in loud and repeated cheers.'

The performance was witnessed by fifty-four gentlemen of science, and of the highest respectability, whose signatures, in my possession, attest the fact. This performance, made nearly two years ago, has exceeded by 70 per cent. any other performance in Europe or America to this day. I have in my possession duly authenticated documents to prove the above, as well as several other performances on the same plane, equally extraordinary. Several of my machines have been kept on duty for fifteen days in succession on the said plane, doing all the duty of the stationary engine, while the same was under repair, dragging up at each trip never less than 25,000 pounds."

The cost of conveyance on the Stockton and Darlington railway is ·4*d*. per ton, per mile; therefore, as ·4 : 66 : : 83 : ·5, which is nearly the cost of the Liverpool engines.

The above calculation will account for the increase of expense of the motive power; but this only amounts to ·125*d*. per ton, per mile, whereas the difference is ·873*d*., leaving ·748*d*. per ton per mile not accounted for. We observe, that the expense of carriages is greater for general merchandise than for coals and minerals; but the great difference exists in the expense of conducting the traffic of general merchandise upon public railways, in receiving and storing, loading and unloading goods, and in the expense of the necessary attendants; none of whom are required for coals and minerals, which are generally loaded and unloaded by the proprietors. The expense of conducting the traffic, including the above enumerated charges, amounts to 1*d*. per ton, per mile, upon the goods, actually subject to the above charges; or ·460*d*. per ton, per mile, upon the aggregate traffic on the Liverpool and Manchester railway. This expense, together with several other items, which will be seen on examining the particulars under the respective heads of charge, incidental to a public railway, with a mixed traffic; will account, satisfactorily, for the difference between the cost of conveying merchandise on such railways, and coals or minerals on railways more particularly applicable to the conveyance of such articles.

It is, however, a question of some importance, how far public railways, with a mixed traffic, and on which passengers are to be conveyed at high rates of speed, are applicable to the economical conveyance of heavy goods or minerals. We have before remarked, that the example of the cost of the Liverpool and Manchester railway, must be taken as being beyond what may reasonably be expected to be the cost of future railways. Taking, however, the cost of that railway, we find the expense of motive power ·55*d*., of maintenance of the railway ·307*d*., and the cost of upholding waggons ·227*d*., altogether 1·084*d*. per ton, per mile. These are the direct expenses, any traffic on which dues above these sums can be charged, will operate to diminish the general or constant expenses of the establishment, and will, therefore, be profit, with the exception of a portion of expense of attendants, &c.; if we take the general charges the same as upon the Stockton and Darlington railway, or at ·100*d*. per ton, per mile, we have the whole expense equal to 1·184*d*. per ton, per mile.

We see, therefore, that the entire cost of conveying minerals or coals along a public railway, with a mixed traffic, will be 1·184*d*. per ton, per mile; without reckoning any charge for interest of capital, or profits, and taking the expense of the Liverpool railway as a standard; and if we take the contract price for haulage, upon the London and Birmingham railway, this will be reduced to 1·134*d*. per ton, per mile. We have already explained, that the expense of the motive power is increased by the diminished load taken at each trip, that the cost of maintenance of the Liverpool railway is greater than may be expected in future; we may, therefore, state, generally, that the direct expenses, exclusive of loading and unloading, and of conveying coals or minerals along public railways, will amount to about 1*d*. per ton, per mile; and that any charge beyond that, will assist in reducing the general expense of the necessary establishment of the railway, for conducting the other traffic.

Chapter XIV contains a short account of the *Construction of the Great Western Railway, and the Locomotive power to be used thereon*;—an interesting subject, which in a future edition of Mr. Wood's work will claim a larger space, to exhibit the results of the various great experiments which are in course of trial upon that line.

An Appendix subjoined to the volume contains much useful information, statistical, experimental and technical, which will amply repay the careful attention of the student.

And here must we close our notice of Mr. Wood's valuable work; our extracts have already run to considerable length, or we should be glad to add a few more. We think however, sufficient samples have been brought forward, to convince the reader of the justice of our opinion, already more than once expressed, in favour of the work before us.

A Treatise on Roads; wherein the Principles on which Roads should be made, are explained and illustrated by the Plans, Specifications, and Contracts made use of by Thomas Telford, Esq. on the Holyhead Road. By the Right Honourable Sir Henry Parnell Bart. Hon. Mem. Inst. C. E. Second Edition. London: Longman & Co., 1838.

It has been said that the English are a nation of Merchants, and of Merchant Princes, whose immense wealth has been obtained by the enterprize which characterizes their commercial relations. In each department of business, the most lively energy is constantly maintained; and so well are its arrangements organized, that as in an immense hive, each member of the community while providing for his own subsistence, is promoting the general good.

To trace the causes of the commercial prosperity of Great Britain, we must look elsewhere than to her naval and military power; which, so far from their having been, as in the case of many other nations, the primary cause of her greatness, have played but a subordinate part in the great drama;—we must look to the spirited manner in which the arts and sciences have been cultivated by her sons, and to the many, great, and important improvements introduced by their persevering and successful enterprize. Foremost among these, appears to stand the continued succession of improvements in Internal Communication. And although, since the introduction of railways and locomotive steam power, we have ceased to be satisfied with less than the velocity of the eagle; yet we should never lose sight of the fact, that this modern innovation has resulted from the increased wants of society, which themselves originated in the improved and excellent state of the common high roads of the kingdom. The commercial prosperity of the country dawned with the improved system of road-making; and to such roads and means of conveyance a debt of gratitude and respect is due, however lightly they may be esteemed by the exclusive admirers of the new and astonishing velocity of modern locomotion.

These thoughts were suggested to our mind by the appearance of a second edition of Sir Henry Parnell's excellent Treatise on Roads;—a work that should be not only in the hands of every person in any way connected with the highways of the kingdom, but also on the shelves of every public library as a standard book on a subject of universal and permanent interest. The new edition has been improved by the addition of a chapter on carriages, and several new paragraphs and notes, from which we shall proceed to make some extracts.

But first we must observe that although on the whole we highly approve of the work, there are passages which we little expected to see written by an author of such eminence as Sir Henry Parnell. We fear that his long experience of turnpike roads, and the credit which he has deservedly gained both in promoting the formation of the great Irish road by Holyhead, and in chronicling its history, have in some measure unfitted him for coming to a sound and impartial judgment of the merits of the new railway system, which threatens in great measure to supersede his favourite means of locomotion. Thus do we account for his comments on "Iron Railways," which appear to us somewhat behind the age, and in which we do not suppose many merchants or men of business will be found to concur.

The uses and advantages of iron railways with locomotive engines, have of late been so fully explained in several works of great ability, that it is not necessary to repeat in this, what was stated respecting them in the last edition.

The eagerness which was so generally displayed by vast numbers of persons to give credit to the representations of the great profits to be realised by railway shares, gave so much encouragement to all those adventurers, who looked to derive immediate advantage from railway projects, that acts of parliament have been passed for railways in every part of the kingdom. The experience, however, which has been gained from those already completed, and from the enormous expense incurred on those which are in progress, has led to a general opinion that there is little probability of more than a few of these works affording any ultimate return for the money expended upon them.

The heavy expense which is proved by experience to be unavoidable in keeping the railways and engines in repair, where great speed is the object, will in numerous cases soon make it evident that no dividends can be paid to the shareholders; and the cheaper method of using horse power will be adopted. This has recently happened on a railway, where, although the traffic on it was very considerable both of goods and passengers, the cost of using steam power absorbed nearly all the money received; and accordingly, a case having been made out by an eminent engineer to show that if horse power were employed the traffic would afford a dividend, the use of steam power was discontinued, and the result has proved the change to be completely successful.

What seems to have been the great error on the part of those who have introduced the modern railway system, was making excessive speed the main object of it. It is this which has led to the enormous expense, 1st, as to the gradations of the lines; 2dly, as to the strength of the construction of rail ways; and 3dly, as to the engine. But the attaining of the speed of 25 or 30 miles an hour, at such an enormous expense, cannot be justified on any principle of national utility. The usefulness of communication, in a national point of view, consists principally in rendering the conveyance of all the productions of the soil and of industry as cheap as possible. This keeps down the prices of food, the prices of raw materials, the prices of finished goods; and thus increases the consumption of all productions, the employment of labour and capital, and generally the national industry and national wealth. But a speed of 10 miles an hour would have accomplished all these purposes, and have been of great benefit to travellers, while it could have been attained at from one-half to one-third of the expense which has been incurred by the system that has been acted upon. It is no doubt true, that travelling at the rate of 25 or 30 miles an hour is personally very convenient, but how it can be made to act so as to contribute very much to the benefit of the country at large, it is not easy to discover. Economy of time in an industrious country is unquestionably of immense importance; but after the means of moving at the rate of ten miles an hour is universally established, there seems to be no very great advantage to be derived from going faster.

Sir Henry might just as well have argued, that because excellent

sailing vessels had been established between London and Edinburgh or Paris, there was no necessity for introducing steam-boats on these stations;—or that because some of the finest sailing vessels in the world were plying on the line from England to America, there was no advantage to be gained from steaming across the Atlantic. Very few persons we conceive,—excepting perhaps here and there a timorous old maid,—will agree with the author that it is no very great advantage to be able to travel from London to Liverpool in six or seven hours, or from London to New York in fourteen days. But we have interrupted Sir Henry in his observations; he proceeds thus—

The use of steam power and the practice of keeping up an excessive rate of speed, has necessarily led to high charges for carrying passengers and goods. A slower rate of speed would, by diminishing expense, admit of the charges being moderate, and in this way the national interests would be best promoted. The object in making railways, ought from the beginning to have been, the reduction of the cost of moving passengers and goods to the lowest possible limit, and not excessive speed. This would have made the money applied to railways go much farther in extending them over the face of the country; the risks of accidents would have been almost wholly avoided; while the charges for travelling and transporting goods would have been considerably less. It is however right to admit, that if the raging passion for excessive speed had not been gratified, subscribers probably would not have been found for forming railway companies, and what was really useful and necessary in substituting railways for common roads would never have been accomplished. The public, in fact, are alone to blame for the immense waste of money which has taken place in forcing an excessive rate of speed, and in producing that superfluity of embellishment and grandeur which is to be seen on all the railways.

The chapter on *Repairing roads* contains the following note by Mr. M'Neill, describing an experimental "road made partly with broken stone, and partly with pieces of cast metal, laid on over a sub-pavement of rubble stone."

This plan has been lately tried on a part of the Holyhead Road between London and Birmingham, and appears to possess some important advantages, which however can only be ascertained with certainty by a trial on a more extended scale, and in a situation where there is a much greater thoroughfare of horses and carriages.

The plan simply consists in laying pieces of cast metal on the surface of the road, previously well constructed in the manner recommended by Mr. Telford, and adopted in all the new works on the Holyhead Road; that is, with a rubble pavement of large stones, covered with six inches of good hard broken stone. This layer of stone should be laid on in two successive operations; the first coat should not be more than three inches thick, and should be kept constantly raked until it becomes nearly consolidated; the second coat should then be applied, and raked in very carefully the moment a carriage track appears in it. When this coating becomes consolidated, so that a carriage can pass over it without leaving a rut, the iron may be applied. This may be done by a labourer. He should be provided with an iron instrument similar to a marline spike, and about twelve inches long; the upper six inches should be round, and the lower six should be tapered down to a square point. With this tool and a mallet, a hole should be made in the road large enough to receive the cube of metal, which should be stuck firmly down, until the upper surface of the iron is on a level with the surface of the road. The stone chip caused by making the hole, should then be packed round the iron, and beat down by the mallet. One of these iron cubes should be placed in the manner above described in every four square inches of surface, and the road, if the work be done in summer, should be frequently and copiously watered, until the iron cubes become perfectly fixed and firm in their places, which will be the case in three or four days, even with a limited traffic over the road.

It was in this way that the experiment was made on the Holyhead Road; the cubes of iron were put in in the month of March, 1835, and became consolidated in about three days: very few were thrown out of their places by the horses' feet or the wheels of carriages during the period; and after they became consolidated there was not one observed to move. They have been now on the road two years, and they appear to have suffered scarcely any wear. The road has remained in a very perfect state up to the present time; and during the whole of last winter, which was singularly unfavourable for roads, it has required scarcely any scraping, and no repairs whatever from the time it was first laid down. There is nothing in the appearance of the road to indicate that it is at all different from common stone roads, and it requires a close examination to detect the iron. The horses do not slip in the least, and the wheels of carriages pass over it apparently with great ease of draught.

In streets, iron may prove of great advantage, as it will certainly diminish to a great extent the nuisance of constantly picking up the surface and laying on new materials. The iron of which the cubes are cast, may be of the very worst and cheapest description, and will probably not cost the third part of common castings.

Chapter XIII, *on Carriages*, contains some judicious remarks, and points out the mode that should be adopted in their construction in order to produce the least injury to roads, and at the same time to promote the best interests of coach proprietors, and the convenience of the public.

As the expense of maintaining a road in good order depends in some degree upon the sort of carriages which are made use of, a few remarks on different kinds of carriages may be introduced with propriety into this work.

When a road has been made with very hard materials, and it has a very smooth surface, a wheel in rolling over it, even bearing a great weight, does very little injury; but when it has been made with weak materials, a wheel cuts and injures the surface in proportion to the weight it carries. The general ignorance of road-making on right principles, led all those who first undertook to improve the roads to attempt to make bad materials do as well as good ones, by regulating the breadth of the tires of wheels, and by limiting the weight to be carried on them. The consequence was, a great quantity of absurd legislation, and no improvement in the roads; and this, simply because it was impossible to make a good road with bad materials. If roads were made sufficiently strong and hard, of a proper form, and kept well drained and scraped, the only case in which the legislature need interfere, is to prevent the injury that wheels do which have nails projecting above the tires of them. With such roads, the interests of carriers of all kinds would lead them to make use of no other than one horse carts, as in Scotland and Ireland, and then the loads would never be so great as to produce any injury to a perfectly good road.

The experience of the use of one horse carts in Scotland and Ireland shows, that a much greater weight can be drawn by horses when working single than when they are joined together. The reason of this is, that it is impossible to make two or more horses exert their strength so that each horse shall regularly and steadily draw its proper share of a load. The common load of a one horse cart in Scotland and Ireland is 30 cwt., exclusive of the cart, while the average load that a horse draws in an English waggon is no more than 15 cwt., exclusive of the waggon.

The most simple and effectual way of getting rid of the injury which very heavily laden waggons do to roads would be, to increase the rate of toll on any additional horse; for instance, if the toll was 4d. on one horse, it should be 10d. on two, 17d. on three, and so on.

With respect to carriages used for carrying passengers, it would appear that the business of building carriages not having been interfered with by the legislature has been carried on very much to the advantage of the public. In other countries, France for instance, it is otherwise, for the shape and slow rate of moving of a French diligence is wholly owing to a most absurd regulation respecting the breadth of the tires of the wheels. But although stage coaches are so built in England as to allow of travelling with safety and convenience, and at a cheap rate, the comfort of travellers might be increased, and the labour of horses diminished, if the body of a coach were made larger, the fore wheels made higher, the springs made longer and slighter, and the weight made to rest chiefly on the hind wheels. * *

Although science, if properly applied, will certainly lead to improvement in the construction of coaches, a series of experiments should be made, in order to determine, with complete accuracy, what is the full effect of wheels, springs, and good roads in diminishing the labour of horses.

Mr. M'Neill's invention of an instrument for trying the draught of carriages, which has been found to be perfectly fit for the purpose, now admits of such experiments being made with a certainty of leading to accurate results; and it is very important that they should be made. In point of fact, although the extracts which have been taken from works of science are quite sufficient to convince all persons who have received a scientific education that the fore wheels of a coach ought to be high, and that the greater part of the load should be placed over the hind ones, as it happens that few of those persons who are concerned in the directing of the building and in the building of coaches have ever applied themselves to scientific inquiries, so as to know either why spokes are called levers, and what the property of the lever is, or what the effects are of the friction of wheels in turning on their axles and in moving on roads, it is quite necessary that experiments should be made, so that, by showing how much work horses actually do in drawing different kinds of carriages, nothing shall be left wanting to expose the prevailing errors with respect to wheels, and the proper manner of loading coaches.

As Mr. M'Neill's instrument can be fixed to a coach, with the horses to it, what it shows is, the actual force or labour which they exert in drawing; and, therefore, the experiments made with this instrument are not liable to errors, like other experiments, where it is necessary to use a substitute for the real power.

The expense of making a proper set of experiments would amount to some hundred pounds: as, however, there exists nothing to make it worth the while of any private person to incur it, those experiments should be ordered and paid for by government. This small expenditure would soon be repaid by the saving which would be effected by diminishing the labour of horses in drawing stage coaches, and, consequently, the expense, which now falls indirectly on the public in providing a sufficient number of them, and maintaining them.

The Churches of London. Nos. XVIII. XIX. and XX. By George Godwin, Jun. F.S.A., assisted by John Britton, Esq., F.S.A. London: C. Tilt; 1838.

This work proceeds with the same spirit as at its commencement; and deservedly increases in favour with the public. The present numbers are interspersed with numerous archæological notices of the Churches, Tombs, and Monuments found in the City.

Sketch of the Civil Engineering of North America; comprising remarks on the Harbours, River and Lake Navigation, Lighthouses, Steam Navigation, Water-works, Canals, Roads, Railways, Bridges, and other works in that Country. By DAVID STEVENSON, Civil Engineer. London: John Weale; 1838.

Of travellers in America, and of Journals published by them on their return; of praises of the Journalizers by their political and religious friends, and of blame and reproach heaped upon them by their political and religious foes; of conclusions drawn by all parties in turn, demonstratively proving the truth of their own views and the soundness of their own principles; we have had, are having, and probably shall long continue to have, a rapid and ceaseless succession. "What's the newest work?" asks the reader of travels, of the provincial circulating-library keeper; and he, looking somewhat dolefully to the accumulations on his shelves, replies

> "That of an hour's ago doth hiss the speaker;
> Each minute teems a new one."

Under such circumstances, we thank Heaven that we are not a literary journal; and can let this mighty current of literature sweep past us unnoticed, and without troubling our philosophical tranquility. Yet it suggests to us one reflection, in which we think all our readers will concur;—whatever they may think of the books themselves, they will agree that that *is*, and *must be*, an interesting country of which so much is written, and—it is to be supposed—so much read.

America *is* an interesting country;—few so universally interesting. It is emphatically the *new* world; and as such it is interesting to every inhabitant of the *old*. The mighty features of this vast continent, its never ending rivers, its wide extended inland lakes, its trackless forests, its lofty mountains, its prairies bounded only by the distant horizon,—all marked it out on its discovery as the land of wonders, and give it continued and increasing importance as its civilization extends, and its natural riches are further and further unfolded. As a new world, it presents a curious and most interesting study to the inhabitants of the old; as exhibiting under new and frequently most unexpected forms, those arts and manifestations of civilized life which it has transplanted from the elder continent. This study, every man will naturally pursue in his own way; the politician will look to American politics; the divine, to American manifestations of the universal religious principle; the naturalist, to American productions in earth and sea and air; the manufacturer and merchant, to American manufactures and commerce. And all will find much to interest them in their peculiar pursuits.

So do we look to American Engineering with lively interest. For British mechanical skill to be placed in circumstances of position so peculiar and so advantageous, without distinguishing itself by its spirit in overcoming difficulties, and its eagerness in availing itself of all favourable incidents, would be a moral impossibility. Nor have our Transatlantic brethren disappointed the expectations which we had a right to form of them. Their noble rivers have not been bestowed upon them in vain; but have furnished them with a grand and most complete system of inland navigation. So too, the vastness of their dominions has forced upon them a vast system of communication by land;—but the force has been gentle, for it has had to work upon what appears to be a kind of natural genius for locomotion And we may safely add, that in all branches of engineering, we have in America a wide field for study, both interesting and useful. A judicious and liberal comparison of British and American practice, cannot but be attended with mutual pleasure and advantage.

It is then with much satisfaction, that we perceive one of the latest American tourists and journal-writers, to have been an engineer, fitted by education and taste, to give us information on these interesting subjects. Nor will his book be read with the less attention, from its coming from the son of the well-known engineer of the Bell-rock Lighthouse.

Mr. Stevenson, taking advantage of a short interval of professional leisure, resolved to visit the Canadas and the most interesting parts of the United States; for the express purpose of examining for himself the much talked of, but little known, engineering works of America. During a tour of three months, he travelled over some thousands of miles, and collected together a vast variety of interesting facts relating to his subject of inquiry. The results, he has published in the present work; not however, as he states, to satisfy the curiosity of engineers in England; but rather to stimulate others who may have it in their power to examine more thoroughly the ground which he has gone over hastily, and to extend their researches further. We have read the "Sketches" with considerable interest; and have little doubt that they will prove equally acceptable to the profession generally.

Mr. Stevenson directs his attention in the first place to *Harbours*, describing the natural facilities which America affords for their formation on her coast;—facilities, he states, such as no works of art alone could supply. After taking a rapid glance at the Bay of New York, and explaining the mode of constructing the jetties, wharfs, and landing places at that port, he notices likewise the other principal harbours, both of the United States and of British America. Two following chapters are devoted to *Lake* and *River* Navigation; which brings us to the most interesting portion of the work, that which relates to *Steam Navigation.*

Whatever differences of opinion may exist as to the actual invention of the steam-boat, there is no doubt that steam navigation was first fully and successfully introduced into real use in the United States of America, and that Fulton, a native of North America, launched a steam-vessel at New York in the year 1807; while the first successful experiment in Europe was made on the Clyde in the year 1812, before which period steam had been, during four years, generally used as a propelling power in the vessels navigating the Hudson. * *

It would be improper to compare the present state of steam navigation in America with that of this country, for the nature of things has established a very important distinction between them. By far the greater number of the American steam-boats ply on the smooth surfaces of rivers, sheltered bays, or arms of the sea, exposed neither to waves nor to wind; whereas most of the steam boats in this country go out to sea, where they encounter as bad weather and as heavy waves as ordinary sailing vessels. The consequence is, that in America a much more slender build, and a more delicate mould, give the requisite strength to their vessels; and thus a much greater speed, which essentially depends upon these two qualities, is generally obtained. In America, the position of the machinery and of the cabins, which are raised above the deck of the vessels, admits of powerful engines, with an enormous length of stroke, being employed to propel them; but this arrangement would be wholly inapplicable to the vessels navigating our coasts, at least to the extent to which it has been carried in America.

We are constantly hearing of such great exploits on the part of the Americans, respecting the performances of their steam-engines, as to excite not only frequent surprise, but also occasional doubt. The reports of Mr. Stevenson are important in this respect, and may tend in some measure to throw light on the construction of American steam-boats and engines.

These steam boats may be ranged under the following classification. first, those navigating the Eastern Waters. This class includes all the vessels plying on the river Hudson, Long Island Sound, Chesapeake and Delaware Bays, and all those which run to and from Boston, New York, Philadelphia, Baltimore, Charleston, Norfolk and the other ports on the Eastern coast of the country, or what the Americans call the Sea board. Second, those navigating the Western Waters, including all the steamers employed on the river Mississippi and its numerous tributaries, including the Missouri and Ohio. Third, the steamers engaged in the Lake navigation. These classes of vessels vary very much in their construction, which has been modified to suit the respective services for which they are intended.

The general characteristics by which the Eastern Water boats are distinguished, are, a small draught of water, great speed, and the use of condensing engines of large dimensions, having a great length of stroke. On the Western Waters, on the other hand, the vessels have a greater draught of water and less speed, and are propelled by high pressure engines of small size, worked by steam of great elasticity. The steamers on the Lakes, again, have a very strong build and a large draught of water, possessing in a greater degree the character of *sea* boats than any of those belonging to the other two classes. They also differ in having masts and sails, with which the others are not provided.

The steam boats employed on the Hudson River are the first, belonging to the class of vessels navigating the Eastern Waters, of which I shall make more particular mention.

* * In order to explain more clearly the general arrangement of their parts and mode of operation, I shall give in detail the dimensions of the steam boat Rochester, plying between New York and Albany. * *

The Rochester measures 209 feet ten inches in length on her deck. This measurement applies also to the length of her keel, her stern post and cut water being perpendicular. The maximum breadth of beam is 24 feet. The projection of that part of the deck called the wheel guards, beyond the hull of the vessel, is 13 feet on each side. The maximum breadth of the vessel measured to the outside of the paddle wheels, is 47 feet. The depth of hold is 8 feet 6 inches. The draught of water, with an average number of passengers, is four feet. The diameter of the paddle wheels is 24 feet. The length of the float boards, which are twenty-four in number, is 10 feet. The dip of the float-boards is 2 feet 6 inches. This vessel is propelled by one engine, having a cylinder of 43 inches in diameter, and the length of stroke 10 feet. The engine condenses the steam, which works expansively, and is cut off at half-stroke.

The great competition that exists in the navigation of the Hudson produces constant *racing* between boats belonging to different companies; and this is not unfrequently attended with serious accidents. When the Rochester is pitched against another vessel, and at her full speed, the steam is often carried as high as forty-five pounds on the square inch of the boiler; and the piston makes twenty seven double strokes, or in other words, moves through a space of 540 feet per minute, or 6,13 miles per hour. In this case

the circumference of the paddle-wheels moves at the rate of 25.13 miles per hour. In ordinary circumstances, however, the engine is worked by steam of from twenty-five to thirty pounds pressure on the square inch; and in this case the piston makes about twenty-five double strokes per minute, moving through a space of 500 feet per minute, or 5.68 miles per hour; and the circumference of the paddle-wheels moves at the rate of 21.42 miles per hour. The rate at which the pistons of marine engines in this country move, seldom exceeds 210 feet per minute. The pistons of locomotive engines, generally move at the rate of about 300 feet per minute; but both of their speeds are very short of the velocity of the Rochester's piston. * *

I found no variety in the construction of the paddle-wheels of the different American steam-boats. * *

The float-boards do not extend across the whole breadth of the paddle-wheels, as is always the case in this country. They are divided into two and sometimes three compartments, and the wheel is furnished with three and sometimes four sets of spokes arranged in parallel planes. "This construction was introduced by Mr. Stevens of New York, and may be described," says Dr. Renwick, "by supposing a common paddle wheel to be sawn into three parts in planes perpendicular to its axis. Each of the two additional wheels that are thus formed, is then moved back, until their paddles divide the interval of the paddles on the original wheel into three equal parts.

"In this form the shock of each paddle is diminished to one-third of what it is in the usual shape of the wheel; they are separated by less intervals of time, and hence approach more nearly to a constant resistance; while each paddle following the wake of those belonging to its own system, strikes upon water that has been but little disturbed." * *

The American steamers are generally propelled only by one engine, and a counter-balance attached to the paddle-wheels is in some cases found necessary, to enable the engine to turn its centres. The great length of the stroke however, allows time for a degree of momentum to be generated, which is sufficient in most cases to carry the engine past its centres; and failing this, the paddle-wheels, from their large diameter, become good generators of momentum, and act in the same way as the fly-wheels of land engines in regulating their motion. Even in those vessels where two engines are employed, their connecting-rods are not attached to the same axle; each engine works quite independently of the other, and drives only one of the paddle-wheels; whereas in this country, the connecting rods of both engines are attached to the same axle, by cranks placed at right angles to each other, so that one engine is exerting its full power at the very moment when the other is expending none of its force, and the power is thus employed in the most advantageous manner for keeping up the speed. The short stroke and comparatively small diameter of the paddle-wheel in European boats, renders this construction necessary to enable engines to pass their centres.

The general construction of the boilers, and the arrangement of the flues, in the steam boats on the Eastern Waters, resemble in a great measure those of European steamers. The flame and smoke generated in the fire place by the combustion of the fuel, pass through flues in the interior of the boiler, and are afterwards discharged into the smoke-tube. The boilers are strengthened in the usual manner, by means of iron braces or ties, arranged so as to form a strong connexion between the interior surfaces, and thus render them more capable of resisting the expansive force of the steam, which has a tendency to tear them asunder.

The vessels which ply on the Western waters, are not equal either in workmanship or speed, to the Eastern water boats. They vary from 100 to 700 tons burden, and are generally of a heavy build, flat in the bottom, and draw from 6 to 8 feet of water.

The hull is covered with a deck at the level of about five feet above the water, and below this deck is the hold, in which the heavy part of the cargo is carried. The whole of the machinery rests upon the first deck; the engine being placed near the middle of the vessel, and the boilers under the two smoke chimneys. The fire doors open towards the bow, and the bright glare of light thrown out by the wood fires, along with the puffing of the steam from the escapement pipe, produce a most singular effect at night, and serve the useful purpose of announcing the approach of the vessel when it is still at a great distance. The chief object in placing the boilers in the manner described, is to produce a strong draught in the fire place.

Who can wonder at hearing of the constantly occurring accidents to American steam-vessels, when he has read the following extract?—

The engines are generally very small in proportion to the size of the vessel which they propel; and, to make up for their deficiency in volume, they are worked by steam of great elasticity. The Rufus Putnam, for example, a pretty large vessel, drawing six feet of water, which plies between Pittsburg on the Ohio and St. Louis on the Mississippi, is propelled by a single engine having a cylinder 16 inches diameter, and 5 feet 6 inches in length of stroke; but this engine is worked by steam of a most dangerously great elasticity. The captain of the vessel informed me that, under ordinary circumstances, the safety-valves were loaded with a pressure equal to 138lb. on the square inch of surface; but that the steam was occasionally raised as high as 150lb., to enable the vessel to pass parts of the river, in which there is a strong current; and he added, by way of consolation, that this amount of pressure was never exceeded except on extraordinary occasions! I made a short voyage on the Ohio in this vessel, but after receiving this information, I resolved to leave her on the first opportunity that presented itself.

The *Fuel* generally employed for steam-engines in America, is wood, which varies in price from 5s. to 20s. per "*cord*" containing 128 cubic feet. Pine timber is considered the best; and about 2½ cords of wood are stated to be equal to one ton of coal, in power of generating steam in well constructed boilers. Anthracite coal is sometimes used, both for steam boats and locomotive engines; but not to any great extent.

The *Canals* of the United States, appear to be of very great extent; and our author gives a very interesting account of them in chapter VI.:—

The zeal with which the Americans undertake, and the rapidity with which they carry on every enterprize, which has the enlargement of their trade for its object, cannot fail to strike as a characteristic of the nation, all who visit the United States. Forty years ago, that country was almost without a lighthouse, and now no fewer than two hundred are nightly exhibited on its coast; thirty years ago, it had but one steamer and one short canal, and now its rivers and lakes are navigated by between five and six hundred steamers, and its canals are upwards of two thousand seven hundred miles in length; ten years ago, there were but three miles of railway in the country, and now there are no less than sixteen hundred miles in operation. These facts appear much more wonderful when it is considered, that many of these great lines of communication are carried for miles in a trough, as it were, cut through thick and almost impenetrable forests, where it is no uncommon occurrence to travel for a whole day without encountering a village, or even a house, excepting perhaps a few log huts inhabited by persons connected with the works. * *

The great length of many of the American canals is one remarkable feature in these astonishing works. In this respect they far surpass any thing of the kind hitherto constructed in Europe. The longest canal in Europe is the Languedoc, which has a course of 148 miles; and the most extensive in the United States is the Erie Canal, which is no less than 363 miles in length.

The *Roads* and *Bridges* of America next engage Mr. Stevenson's attention, in the two succeeding chapters. The timber bridges appear to have no particular limit to the immense span of their arches. The largest spans are formed of wooden arcs, with suspending rods to carry the road-way. The bridge over the Susquehanna at Columbia, is considered the most extensive arched bridge in the world; it was begun in 1832 and finished in 1834.

It is certainly a magnificent work, and its architectural effect is particularly striking. It consists of no less than twenty nine arches, of 200 feet span; supported on two abutments, and twenty eight piers of masonry, which are founded on rock, at an average depth of six feet below the surface of the water. The water way of the bridge is 5,800 feet: and its whole length, including piers and abutments, is about one mile and a quarter. The bridge is supported by three wooden arcs, forming a double roadway, which is adapted for the passage both of road and railway carriages. There are also two footpaths, which make the whole breadth of the bridge thirty feet. The arcs are formed in two pieces, each measuring seven inches broad by fourteen inches in depth. These are placed nine inches asunder; and the beams composing the wooden framing, by which the roadway is suspended, are placed between them, and fixed by iron bolts passing through the whole.

There is another bridge over the Schuylkill at Philadelphia, consisting of a single arch of no less than 320 feet span, having a versed sine of about 38 feet. This bridge has a breadth of roadway of about 30 feet. It has been erected for several years, and is still in good repair and constant use.

Another description of bridge which is much used on the American railways, and sometimes for so large a span as 150 feet, is that called "Town's Patent Lattice Bridge." From the drawings given of it, it appears to us to be similar to that of Smart, for which a patent was taken out some years since in this country. We are not, however, aware of any bridge of large span having been erected in England on Mr. Smart's principle. But we are happy to hear from Mr. Stevenson, of its successful adoption in America; and we trust that the English patentee will be able to avail himself advantageously of the information given in the work before us.

Mr. Stevenson next describes the American method of constructing *Railways*, illustrated by several drawings; but this we may pass over, as being very similar to the information given on the subject in the first number of our Journal. The American *Locomotive Engines* are similar in construction to the English six-wheeled engines, and their cost is about the same.

They are arranged in the following manner, so as to allow the engine to travel on rails having a great curvature. The driving wheels, which are five feet in diameter, are placed in the posterior part of the engine, close to the fire-box; and the fore part of the engine rests on a truck, running on four wheels of about two feet six inches in diameter: a series of friction-rollers, arranged in a circular form, is placed on the top of the truck, and in the centre stands a vertical pivot which works in a socket in the framing of the engine. The whole weight of the cylinders and the fore part of the boiler rests on the friction rollers, and the truck turning on the pivot as a centre, has freedom to describe a small arc of a circle; so that when the engine is not running upon

a perfectly straight road, its wheels adapt themselves to the curvature of the rails, while the relative positions which the body of the engine, the connecting-rods, and other parts of the machinery bear to each other, remain unaltered.

An apparatus called a *Guard* is described and illustrated by drawings; it is attached to the outside of the fore axle of the engine, for the purpose of removing any obstruction that may be upon the rails. It consists of a strong framework of wood, filled in with bars of iron and wood parallel to the sides, like a grating or gridiron. It slopes down from the axle, to within an inch of the rails; and is kept at that height above them by two wheels, two feet in diameter, which run on the rails about three feet in advance of the engine. The outer extremity or point of the framework, is shod with iron and slightly bent up.

A drawing is given, of a locomotive engine used on the Washington and Baltimore Railway, constructed for the combustion of anthracite coal. It is very different in appearance from ordinary engines, having a vertical cylinder, with a vertical tubular boiler. It weighs about eight tons.

The *Gradients* of the inclined planes on some of the railways, appear tolerably stiff. On the Philadelphia and Columbia line, for instance, we meet with gradients of one in 14·6, and one in 21·2. And on the same railway there are numerous curves, many of them very sharp, the minimum radius being so small as 350 feet.

The *Passenger carriages* are described as being—

—extremely large and commodious. They are seated for sixty passengers, and are made so high in the roof, that the tallest person may stand upright in them without inconvenience. There is a passage between the seats, extending from end to end, with a door at both extremities: and the coupling of the carriages is so arranged, that the passengers may walk from end to end of a whole train without obstruction. In winter they are heated by stoves. The body of each of these carriages measures from fifty to sixty feet in length, and is supported on two four-wheeled trucks, furnished with friction-rollers, and moving on a vertical pivot, in the manner formerly alluded to in describing the construction of the locomotive engines. The flooring of the carriages is laid on longitudinal beams of wood, strengthened with suspension-rods of iron.

We rather expect that in winter, the passengers in some of the large railway carriages at home, will feel the want of the American luxury of a stove inside.

Under the head of *Water-works*, in chapter X., we learn that the supply to many of the large cities, is obtained by water power. The most extensive works of this kind are the Fairmount water-works at Philadelphia; on which it appears that the sum of 276,206*l.* had been expended up to the year 1836. A dam, 1,600 feet long, has been erected across the river Schuylkill; and the water is raised to an elevation of 92 feet by means of six double acting force-pumps, having a stroke of six feet, and each raising daily on an average 530,000 gallons. The pumps are worked by six water-wheels, varying from 15 to 16 feet in diameter, 15 feet in breadth, and making 13 revolutions per minute. The water is conveyed from the reservoirs and distributed through the town, by means of 98¾ miles of cast-iron pipes from 3 to 12 inches diameter, and two mains of 22 inches diameter.

The supply of water at New York, is from wells sunk in different parts of the city, and raised by steam power to elevated reservoirs, whence it is distributed by pipes.

One well, belonging to the corporation, is 113 feet in depth. For the purpose of collecting water, there are three horizontal passages leading from the bottom of the well, which measure four feet in width, and six feet in height; two of them are seventy-five, and the third is one hundred feet in length. * * This mode of collecting water in subterraneous galleries has been successfully practised in this country, on a great scale, at the water-works of Liverpool, by Mr. Grahame, the engineer to the Harrington Water Company.

The chapter on *Lighthouses* describes their construction and lighting apparatus; and gives various particulars relative to their annual cost, their number, management, and other circumstances.

The concluding chapter is on *House-moving*;—rather a curious trade, and very little known in England, though we believe it was practised in the neighbourhood of London, some years since. Mr. Stevenson very minutely describes the process as adopted in America, and gives sketches of the buildings removed, and the apparatus employed.

I saw the operation put in practice on a brick house, at No. 130 Chatham-street, New York, and was so much interested in the success of this hazardous process, that I delayed my departure from New York for three days, in order to see it completed. The house measured fifty feet in depth by twenty-five feet in breadth of front, and consisted of four storeys, two above the ground-floor, and a garret-storey at the top, the whole being surmounted by large chimney-stacks. This house, in order to make room for a new line of street, was moved back, fourteen feet six inches from the line which the front wall of the house originally occupied. * *

I understood from Mr Brown (the contractor) that the whole operation of removing this house, from the time of its commencement till its completion, would occupy about five weeks; but the time employed in actually moving the house fourteen feet and a half, was seven hours. The sum for which he had contracted to complete the operation was 1,000 dollars, which is equal to about 200*l.* sterling. Mr. Brown mentioned that he and his father, who was the first person who attempted to perform the operation, had followed the business of "house-movers" for fourteen years, and had removed upwards of a hundred houses, without any accident; many of which, as in the case of the one I saw, were made entirely of brick.

Notwithstanding our copious extracts from this interesting work, there are several parts that we have not been able to allude to; in conclusion we beg to refer the reader to the volume itself, which we are sure will amply repay an attentive perusal.

British and Foreign Review, No. XIII: *Christian and Pagan Architecture.*

Wherefore this article should be so headed in the publication itself, while in the advertisements it is entitled "The Spirit of Architecture," the editor can best explain. Probably the last-mentioned title was an after-thought, and adopted as being more likely to catch attention than the other; and, in fact, it led us to anticipate something quite fresh on the subject, whereas the article turns out to be little more than a dissertation on the very hackneyed subject of the Grecian and Gothic styles, tacked to "Hope's Historical Essay on Architecture," which is made to serve as the text of it. Still, a clearer exposition of the subject than has hitherto been given, would have been acceptable; instead of which we find it mystified to such a degree as to be rendered nearly incomprehensible—at least to those who are not accustomed to the more subtle and refined speculations of criticism, or to such fanciful language as the following:—

In the fifteenth century, it (namely pointed architecture) came to its end. The powerful but genial winter, the time of inner life, of concentrated unity, was accomplished; and that unity by the love of its being, was now to branch forth, to bud out, to blossom into multiplicity again. And how could the age of Raphael and Michael Angelo, and of Luther, the age of Shakspeare and Cervantes, any longer endure the devout monotony of the pointed style. With the expansion and cultivation of the nature of men, using the word nature as opposed to the supernatural, there returned of course the ancient doctrines; the semicircle and rectangle, the happy medium between excess and deficiency, the full development and even balance of perfect form, once again were loved and understood.

It may be intended to enlighten, but this kind of writing, we suspect, is far more likely to bewilder the reader than to inform him, by conveying any clear ideas on the matter. Even when something of a meaning is got out of it, to what does it amount?—what information does it convey? Hardly any thing that can fairly be called practical. Of speculation and theorizing on the origin and original character of different styles, we have had enough—almost *ad nauseam*—without being as yet hardly a single step nearer any sound and sufficient system of design adapted to our actual purposes and habits, than we were at the very outset of such inquiry. Each writer has in turn gone over the same ground, has examined it, according to his own fashion, up to the very same point, and has there abandoned it, without making the least effort to carry on his inquiry further, and deduce from it some clear and definite principles. No one that we are aware of, has yet attempted to show by various instances drawn from actual buildings of recent times, how far the styles adopted for them have been followed consistently and successfully; how far and in what respect their proper character has been mistaken; or whether in any such buildings, ideas are to be detected for carrying on and working out the style adopted, so as to render it more pliable and manageable for purposes different from those which first called it forth. Whether particularly useful or not, such an inquiry would at least possess some novelty of interest, and might elicit what has hitherto been overlooked.

In the article before us, one of the cleverest and most perspicuous remarks is this:—

The utility of a thing is its utility, and its beauty is its beauty; nor can we by any juggling equation get rid of either term, or make one stand for the other.

In this pithy sentence the writer completely nullifies the doctrine that beauty has its origin in, and is identified with utility; a doctrine to which we ourselves are opposed, though we do not deny that the satisfaction derived from any work of architecture is greatly increased when we perceive that both beauty and utility are made mutually to enhance each other;—that what is done for convenience increases beauty, and that what is done for the sake of beauty increases convenience also.

But when we read what follows almost immediately afterwards, we very much doubt whether such transcendently philosophical

matter will not be considered by most readers as little better than refined jargon :—

All beauty, then, is an outward expression of inward good; and either of that which is good for all soul as soul in itself, and exercising its two prime faculties of expansion and concentration, of grandeur and harmony, or else for what is good for the individual being in particular forms of life. Consequently the highest beauty of individual things is exhibited, when the thing is such as to be susceptible of the most intimate combination with the most universal forms. According to such views we would lay down this definition, that the art of so treating objects as to give them a moral significance, is *the fine art*. As in arithmetic the fractional numbers must be reduced to relative unity with some one whole before they can be managed; so, we affirm, must the partial existences of the visible world be reduced to a kind of common denomination with those of the inner world, before they can be available as expressions, to use another mathematical term, of beauty; and be the thing *a*, *b*, or *c*, we believe that by skilful treatment of its form, it may be brought to have such a meaning.

To which we say, that had the writer illustrated the drift of all this by some well-selected cases that would have served to illustrate and explain it, we might then have been able to work out the meaning of it. At present it reads to us not like nonsense, but as something quite beyond the sphere of common sense and the reach of ordinary faculties. Whatever, therefore, they may be intended to do, papers of this description are not calculated to instruct either the general reader or the professional man on the subject, but rather to involve it in a labyrinth of strange-fangled phraseology.

LITERARY NOTICES.

The great length of our remarks on the Commissioners' Report on Railways in Ireland, compels us to postpone the consideration of several works which we intended to notice.

A Dictionary of the Architecture and Archæology of the Middle Ages, &c., with etymology, definitions, &c.; also biographical notices of ancient Architects: by J. Britton, F.S.A.—We have not been able to devote to this work that attention which its importance demands; and consequently we must defer our remarks upon it till the next number.

Geology as a Science applied to the reclamation of Land from the Sea, the construction of Harbours, the formation of Railroads, and the discovery of Coal; by John Rooke.—A work comprehending such important applications of geology, requires a careful and considerate perusal, before we can presume to give an opinion upon its contents; it will be noticed in the ensuing Journal.

The Arcanum; comprising a concise theory of practical, elementary, and definite Geometry, exhibiting the various transmutations of Superfices and Solids; by John Bennet, Engineer: Nos. 3 and 4.—The title so fully expresses the object of the work, that it does not require of us to say many words respecting its contents; it contains many geometrical figures ingeniously divided and subdivided in a variety of ways.

Mr. Lawrence's new work on Perspective, requires consideration; it shall not be delayed longer than next month.

Mr. Hughes's work on the Practice of making and repairing Roads, contains much useful information for the engineering student; it is also published at a low price, which is another recommendation. We shall not omit to notice it next month.

A Practical Treatise on the construction of Stoves and other Horticultural Buildings, by J. W. Thompson;—contains, so far as we can judge by a cursory glance, a great deal of information illustrated by numerous wood-cuts, and in a very unassuming and cheap form. We recognise with pleasure Mr. Thompson's "economic egg-shaped boiler," of which he furnished us with a description and drawings in our 2nd number, p. 25.

ORIGINAL PAPERS, COMMUNICATIONS, &c.

RALPH REDIVIVUS.—No. 9.

THE ROYAL INSTITUTION.

In selecting the building in Albemarle-street for the subject of my present article, I purpose to make use of it chiefly as a text for certain general remarks; there being in fact little in the design itself that does not discover itself at the first glance, without awaiting further investigation. And as it seems that Omega continues to read my articles, notwithstanding he holds them to be utterly worthless, I may be allowed to address a few more words to him, explanatory of the course I have pursued and to which I intend to adhere. In undertaking this series, one primary object with me was, to infuse a little life and spirit into architectural criticism, which has hitherto been for the most part dry in tone, scanty in observation, and superficial in remark. For saying this, Omega will consider me a very impudent fellow. Very possibly he may there be quite right; nor can he on that score tax me with inconsistency, for I have never in the course of these lucubrations affected modesty, or spoken with a "by your leave" timidity, as if fearful that I was getting quite out of my depth. The very circumstance of a man's assuming to himself the office of critic, is tantamount to a declaration that whether qualified or not, he at least considers himself qualified to direct the opinion of others; or if he doubts it, his modesty is in inverse ratio to his own misgivings.

It is not for me to assert that every opinion I have expressed is incontrovertible; it is enough for me to be able to declare that I have spoken in sincerity, and that so far from passing peremptory judgment in a few general terms, in the *sic volo sic jubeo* style, condemnatory or laudatory as may be, I have invariably endeavoured to explain my reasons, even at the hazard of occasionally appearing to be prolix, and to advert most circumstantially to every particular. So far I may arrogate to myself the merit of having done something towards improving architectural criticism, by endeavouring to rescue it from the dryness and inanity which have pervaded almost all that has hitherto passed for such. Nor will my attempt be much the less serviceable, even should some of the opinions I have promulgated be found on examination to be erroneous; since owing to their being so fully stated, their correctness or incorrectness manifests itself the more clearly. Consequently those who dissent from me, will at least know what it is against which their counter opinions ought to be directed; and thus be able to dispute the debateable ground with me inch by inch. My saying all this will, no doubt, be considered very egotistical: the excuse must be, that I have been in a manner compelled to vindicate myself from a sweeping charge of incompetency for the task I have undertaken in these papers. With which observation I here dismiss a matter to which I do not intend to recur again, unless the necessity for doing so should be forced upon me.

This preliminary over, I now commence my strictures on the new façade in Albemarle-street, by observing that it is precisely the sort of thing calculated to pass with the million for grand and classical; though it can hardly help offending the judicious, and disappointing those who are unreasonable enough for something betokening originality and gusto. It just suffices to convey to us the notion of the effect that would be produced by a continued range of Corinthian columns, executed upon such a scale that the order itself may be called majestic. Yet what great merit is there in that, if everything besides tends to contradict, to interfere with, and to vitiate, the effect apparently proposed? Undoubtedly the first glance promises well enough; but then it is only to disappoint us the more when upon coming up to the building, we discover what it actually is, and begin to scan it more closely.

We then perceive that we have been deluded at a distance by a mere architectural *mirage*; and that the fancied colonnade in front of an edifice of corresponding character, turns out to be a row of semi-columns, placed against the piers of a house whose windows fill up the spaces between them. There being three tiers of windows within the height of the columns, is a favourable circumstance inasmuch as it gives a suitable intercolumniation to the order itself: in every other respect, however, the great number of windows decidedly produces a character totally at variance with that which should attend the order. Had there been either the columns without the house behind them, or the house without the columns, we should have less reason to be dissatisfied. At present, the eye is offended by the palpable incongruity of decoration, so exaggerated as to make the thing intended to be adorned appear quite contemptible—absolutely put out of countenance by the finery heaped upon it.

The whole is disproportioned; because there is no proportion observed between the *polyfenestral* building itself, and the range of columns stuck up against it—not the slightest similarity of taste, for that which manifests itself in the windows is altogether of a different kind from that expressed by the order; the latter being vigorous and florid, the former poor, jejune, and wofully insipid.

On such occasions the problem is, not to produce a correct copy of so many columns, in stone or compo,—for that, as the readers of this journal must be well aware, is a matter altogether mechanical,—but to introduce them so that they shall appear *motived* by the idea, and everything else in the design perfectly accord with such features, and be in unison with the fundamental æsthetic note—in other words, with the order. What the architect therefore has to consider, is how he can work up the subordinate features to the same pitch as the principal ones—not, indeed, so as to interfere with them, but so that while subordinate they shall exhibit the same degree of finish, the same study, the same style of decorative detail. Unless this be done, unity of character is forfeited; and though there may be something to admire in parts, the whole will be as incongruous as a painting that should be carefully finished up in some places, and hurriedly slobbered over in others.

Did it happen that architects designed the details of the orders they

employ, instead of copying, there would then be greater excuse than at present for putting forth all their strength in them; because then, the merit attached to them would be their own. An order would then give evidence of the architect's invention; whereas, such being not the case, the least he can do is to take care that by the propriety of its application and the felicity of its effect in his composition, it shall testify both his correctness of taste, and his skill in combination. So very far, however, is this from being generally the case, that one might be pardoned for imagining that columns are oftener than not made to stand in lieu of all further attempt at design, and are the refuge of indolence and incapacity. Take away them, and we shall as often as not, find nothing worthy the name of architecture left; at the same time take away them, and as frequently as not, it will be impossible to discover that they ought to be supplied.

But what has this to do with the building here spoken of? So much, at least, that the last remark applies directly to it; for supposing the order were to be taken away again, no one would miss it, or even if he did, he certainly would not guess from the windows, of what kind it had been; since so far from partaking in any degree of the character of the decoration shown in the columns and their entablature, the scanty mouldings bestowed upon them just serve to express their poverty and feebleness, and nothing more. But even this very meagre degree of finishing, is not extended to all the apertures, the third range of windows having no kind of dressings whatever; therefore as they come in between the capitals of the columns, the contrast between them and those masses of sculptured foliage is positively offensive—harsh, nay almost barbarous. Even had there been no columns at all, consistency would have demanded that if architectural finish were bestowed on any of the windows, it should be extended to all, although not in the same degree; for otherwise we have a mixture of two incompatible modes in the same design. Most probably the architect was apprehensive that if he bestowed any dressings on the uppermost windows, they and the capitals together would have produced a crowded-up and confused appearance. But then if he found that such would be the case, and that his first idea was so unmanageable, it behoved him to discard it, and adopt some other system of decoration for his façade.

Travellers have told us of savages who though otherwise in a state of complete nudity, wear military coats and cocked hats which they have obtained from Europeans in barter for other articles. Undoubtedly a savage so decked out fancies himself to be very splendidly attired, and perfectly *comme il faut* in his costume, notwithstanding that to European eyes he cuts a most grotesque and ludicrous figure. Yet we ourselves act pretty much like the savage, when we attempt to convert a plain building into a classical piece of architecture by the addition of columns and other things that so far from serving to hide its nudity, only render it all the more conspicuous. It is high time for us to have done with this barbarous pseudo-classical taste, which parodies the architectural costume of Greece and Rome quite as extravagantly as our good friend the savage does that of a military dandy.

The architect of the new front to the Royal Institution, will probably say that Rome itself—that is modern Rome—affords a precedent for what he has done; the temple of Marcus Aurelius having been converted into a building for the Dogana, by filling up its intercolumns with three tiers of windows. It is to be regretted then, that he did not adhere more closely to that example, which certainly affords no authority for the style of windows he has adopted, those of the Roman building having a boldness and greatness of manner, the very reverse of that shown in the Albemarle-street one. In the former, the deep friezes and cornices of the windows produce a certain effect arising from fulness, that is in keeping with the expression of the columns.

Another very striking defect in the front of the Royal Institution is, that instead of marking the centre as distinctly as possible, the architect has taken some pains to avoid all indication of entrance, by making the three doors resemble windows, and has thereby greatly increased the general monotony. This flagrant solecism in composition, is accompanied by another; namely that there is no marked termination to the façade, so that it looks after all, no better than a fragment, or as if it was intended to carry it on, along that whole side of the street; whereas pilasters coupled with the extreme columns, or pilasters only, would have served to define the extent of the composition. Had this front risen higher than those of the adjoining houses, so as to distinguish itself by its outline, then, indeed there would have been less occasion for doing so; yet even then, the want of some definite termination would have had a bad effect,—at present it amounts to a most inexcusable fault.

THE PARKS AND METROPOLITAN IMPROVEMENTS.

"Ne sutor ultra crepidam" (Plin.); which apophthegm being done into English and paraphrased, may be taken to mean that "the Duke of Wellington and the Lord Nelson should fight their battles; that the War Office and the Admiralty should amply provide the munitions of war; and that the Architects and Artists should determine and execute the memorials, which are to record and perpetuate their victories." We take this to be plain good sense. We never ventured to offer our advice to either of the abovenamed great commanders, during the campaigns of the one, or the cruises of the other; but if we had, we feel fully confident that (had we been answered at all) the reply would have been, "Ne sutor ultra crepidam."

This interference in things out of the range of our usual studies leads to strange anomalies. We have a committee, who in all probability now for the first time had the subject forced upon them, placing an equestrian statue contrary to all established rules of propriety, and avoiding an inconvenience by substituting an absurdity. We have men of the highest rank and intelligence in the country, striving to one great point; but intrusting to a small interested party—interested as working for a favourite—a work, in the arrangements for which they have shown themselves equally regardless of its merit as an example of high art, and of its position as a public monument. As a climax, we have a retail dealer from the East of Temple Bar (by the same heaven-inspired talent we presume) giving a public lecture to the Earl of Liverpool on the conduct he ought to pursue under the existing circumstances; and urging from his little desk at the back of his counter, his sense of propriety, on the noble and highly-gifted peer. To all this we say again and again, "Ne sutor ultra crepidam."

Having thus, *in our opinion at least*, established our right to be heard, *we* proceed to offer a few remarks on the proposed Wellington memorial; only adding that they were written and circulated in manuscript before the effigy *which has verified all our observations*, was placed upon the arch.

The object proposed to be attained by placing the statue of his Grace the Duke of Wellington on the arch in Piccadilly, is to give *it a position from whence it will be well seen.* Let us therefore examine the several points of view at which it will present itself to the spectator; and we shall immediately perceive that IT, *in no one instance*, comes in happily with the surrounding locality.

Assuredly not from the upper part of Hyde Park; for the ground rises so rapidly towards the North, that the enormous mass will from thence, be seen upon so low a pedestal—the arch itself being entirely lost—that it will appear to have sunk it into the earth.

On a nearer approach, it will appear to stand on the light and elegant colonnade; and when we have passed that barrier into Piccadilly, it will be seen at an angle and an elevation most detrimental to its effect. The height must also be very materially increased by another and more narrow attic, or one half of the horse will be masked by the projection of the cornice of the order.

It will NOT be seen on the spectator's approach to it from St. James's Street along Piccadilly, *until he has passed Park Lane.*

On the approach from Wilton Place and Knightsbridge, it will be seen rising over the Hospital, to which it may appear to be an accessary, until on nearing it, the hospital masks it entirely.

From the Park Road Westward (from Kensington), *it will not be seen at all.*

From these considerations it will be evident; that although on the first suggestion, the position may appear to be a commanding one, it is in effect, owing to the surrounding buildings and the line of streets and roads, less desirable than could possibly be imagined.

We are happy however in being able to indicate a point, but *very little removed* from that position, which combines every advantage, and of which we have made a plan, the lines of the streets being carefully copied from the parish plan in the Vestry Clerk's Office of St. George's, Hanover Square.

That point is IN THE GREEN PARK, OPPOSITE HAMILTON PLACE. It forms a point of intersection of the visual ray, FIRST from the top of St. James's Street; SECONDLY from Wilton Place, Knightsbridge; THIRDLY from Hamilton Place and the Park beyond; by a curious coincidence, from the Great Western Road of Hyde Park; and it is equally well seen from St. James's Park and Buckingham Palace. We most respectfully recommend this site to the committee.

But is there not something of precipitation, in thus adopting an equestrian statue for the Court end of the town, because the City has determined to have one in the East? The former can by possibility only excel the latter in size; and as by the same possibility it can scarcely be better than Sir Francis Chantrey's,—*and may be worse,*—the faults will be more evident in its increased volume. Bombast and

the colossal are however very nearly allied; they are alike the craving of a distempered appetite, and the bane of taste.

And *if adopted*, we do not see how the several enrichments and ciphers of Royalty can be made to accord with the intended statue. Are they to be removed, and others substituted? And where are the inscriptions to be placed that shall legibly inform the world, that the statue on the summit is the effigy of the Duke of Wellington, and not of George the 4th, to whom all the accessories have allusion?

In what position is the statue to be placed? Is the head to point North or South? There are objections to both positions; but if placed on the longer line of the pedestal, it will be placed contrary to all precedent and propriety.

With these numerous and very substantial objections both to the subject and the situation, how much more appropriate to the cause, would be the adoption of the military column of the Romans! Imagine for a moment the Column of Trajan on the spot we have designated. Forming a vista to the most frequented approaches of the town, it would at the same time rear its summit high over all the metropolis, and be visible for a large circuit of surrounding country. Its sculptured face would hand down to distant ages,—as the Trajan and Antonine columns do at this day—the banners and costumes of the several regiments engaged in perilous warfare under their great commander, whose statue crowning the whole, would complete the spiral line of glory.

August 6th, 1838.

We hope that the discussions that have taken place, will make the Wellington Memorial a subject of competition both for *site* and *subject*. We herein offer our opinion on both points,—and send in our design. When a discovery is made of a hitherto unknown country, it is customary to place the nation's flag upon the spot, and the usages of civilized life have given the sanction of law to the act. Under this acknowledged feeling, we claim the site we have described, and fix our banner upon it. It may be said that any one could see that the site would be a good one. In answer to this objection however, we only refer to the well-known story of Columbus and the egg; which is told also of Bruneleschi the architect of the church of St. Maria del Fiore at Florence. As these two great men were contemporaries, the fact probably occurred at that time, and has been attributed sometimes to the one, sometimes to the other. Our "esprit de corps" would give it to Bruneleschi.

J. H.

ON THE CONSTRUCTION OF SKEW ARCHES.

(*Continued from page 280.*)

At the conclusion of my last article, I find that I committed an error in consequence of having inadvertently followed Mr. Fox's essay; by stating that the axis of the arch, to which the beds of all the stones ought to point, was the centre of the circle of which the surface of the centering was the circumference. This is not, *strictly speaking*, correct; for it will be obvious to the attentive observer, that as all the stones are drawn at right angles to a tangent of the ellipse, those stones which are nearest to the base of the arch will have a centre higher up in the arch than those at the crown; as every person acquainted with an ellipse well knows. As however, all parts of the beds of the stones must be at right angles to the tangent of the curve of the arch, this correction will at once be self-evident to the reader.

The situation of the cross joints, is the next thing which demands our attention. When an arch is built entirely of stone, the courses will all run in parallel lines, as indicated by the dotted lines at S, fig. 11; and the situation of the cross joints will therefore be of little importance, provided that no two joints are made to come together. As however, the majority of skew arches are constructed of brick with stone fronts, the cross joints then become of greater moment; as it is always desirable to obtain an equality of pressure, by making the bearing surfaces of the stones as nearly as possible of an equal area. If the soffits of all the stones are of the same length, the bearing surfaces will be very unequal; as will be evident from an inspection of the diagram fig. 7, the beds of the stones being indicated by the letters A A. In Mr. Fox's essay, this evil is proposed to be remedied by making the beds of the stones of equal length in the middle, as shown in fig. 8, where the *equal* lengths are indicated by the dotted lines. This plan however is liable to some objections. In the construction of a brick arch with stone fronts, the most common method is, to make the soffits of all the stones forming the face of the arch alternately long and short; not only because this presents the best appearance from beneath, but likewise because the stone and brick-work become thereby more firmly united. If therefore two lengths be determined upon, for the soffits of the stones to the depth of about one brick, the upper part may be cut into any form which the builder may think most proper to obtain as nearly as possible an equality of area for the bed of the stones; and the appearance will thus be improved.

The skew backs next come under our notice. In a straight arch, the springing courses of the abutments are *of course* parallel to the horizontal courses; but in a skew arch, they are cut in notches resembling the teeth of a saw. The size of each of these skew backs is of little importance; but if the arch is to be built of brick, the shortest side of each ought to be equal to a certain number of courses of brick-work; and the courses must be at right angles to the approximate line *a. b.* fig. 11. Fig. 9 represents part of the abutment of a skew arch, with the skew backs cut each equal to three courses of brick-work.

Fig. 7.

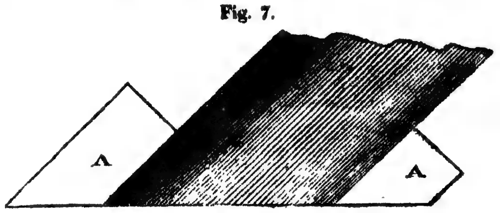

Fig. 8.

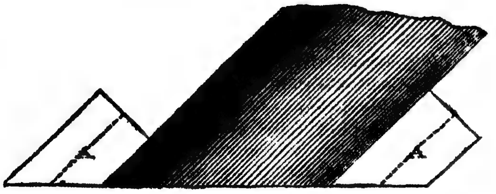

Fig. 9.

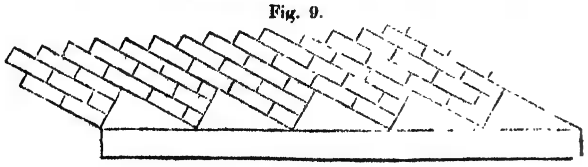

Fig. 10.

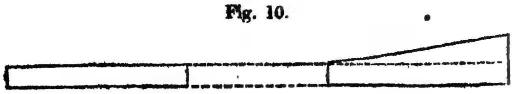

Fig 11.

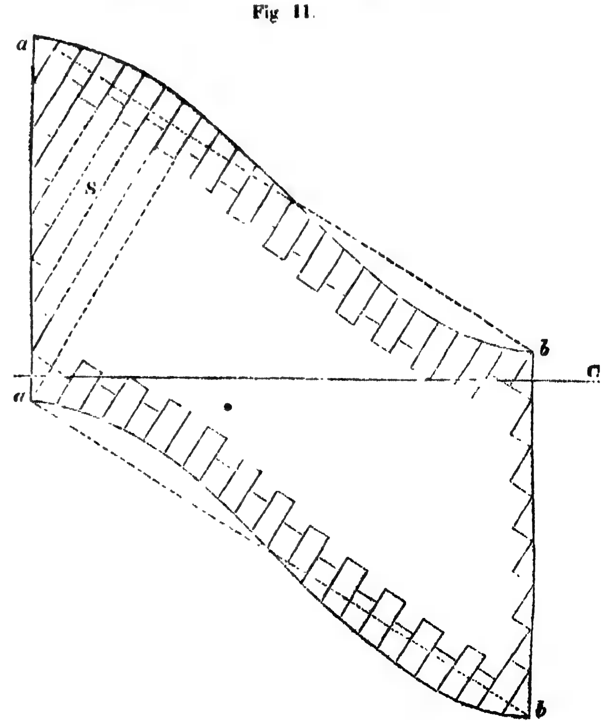


The mode of working the winding beds of the stones, as described by Mr. Fox, is well worthy of adoption both on account of its simplicity and its certainty. As his essay may not be in the hands of all your readers, I may perhaps be permitted to transcribe it in the author's own words. "Having provided two straight edges, the one parallel, and the other containing the angle of the twist (see fig. 10), we proceed to work one of the beds, by chiseling two draughts along the stone, so that these straight edges being kept at a proper distance from each other are let into the stone, until they are out of winding on their upper edges. Having finished one bed by means of straight edges, we then obtain the soffits and the other bed by means of a square, one limb of which is made the curvature of the soffit, and the other the radius of this curve."

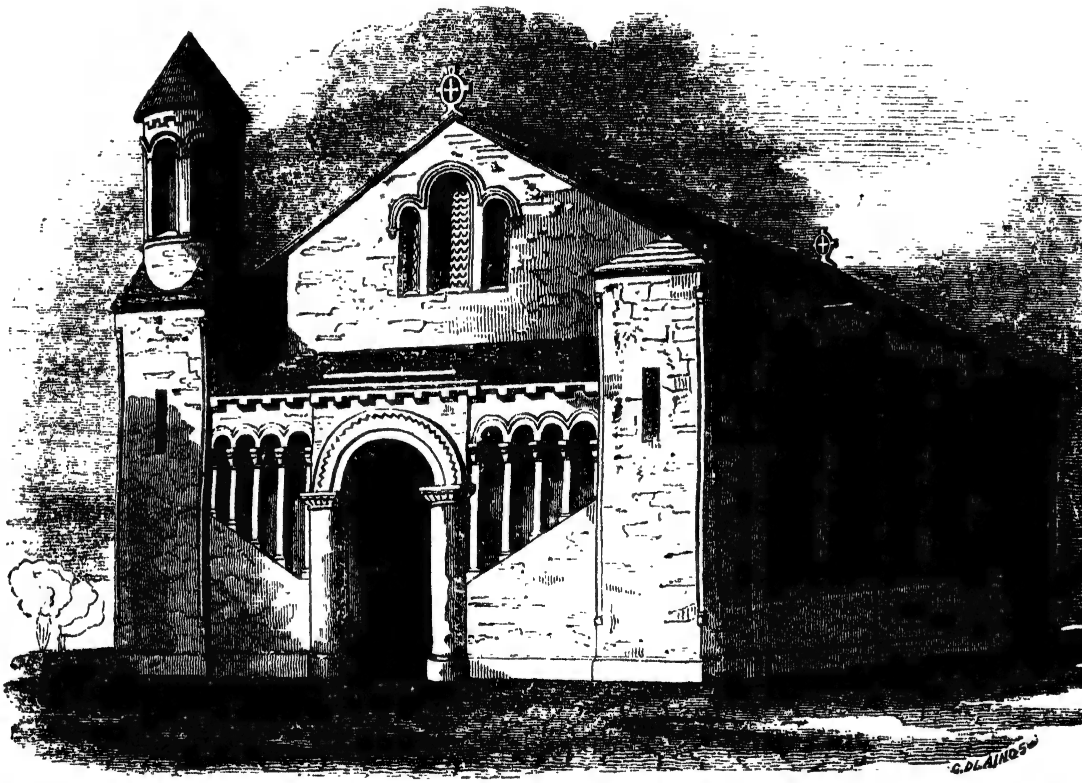
Fig. 11 represents the soffit of a skew arch unfolded, the angle being 45 deg. In this diagram, the skew backs are each made of the same width as the voussoirs, as must be the case if the arch is built entirely of stone; when the interior of the arch is of brick-work, this (as before observed) is not of much importance. If this figure be bent round to an exact semicircle, it will represent the whole of a soffit of a skew arch, at an angle of 45 deg. The line C C is merely intended to show by comparison the analogy between this diagram and the one marked D, fig. 3, page 279.

In the construction of these arches, some masons prefer dressing the face of the stones after the arch is erected; as thereby any little irregularity in the arch stones may be corrected more easily.

To those builders who are unacquainted with this subject, a small model will prove more useful than the most elaborate description. The centering may be formed of a piece of stiff pasteboard; and the voussoirs cut out of cork or soft wood; and if constructed agreeably to the rules here laid down, it will render the subject both simple and interesting to every practical man desirous of becoming acquainted with the more difficult and scientific parts of his profession. C. L. O.

CHAPEL ABOUT TO BE ERECTED NEAR CARDIFF.

BENJAMIN FERREY, ESQ. ARCHITECT.



This chapel which is about to be erected by the Marquis of Bute, in the immediate vicinity of Cardiff, from the designs of Benjamin Ferrey, Esq., although upon a small scale (about 70×35 feet), and sufficiently economical in regard to decoration, is marked by considerable piquancy of character and architectural effect. As the design of the exterior is sufficiently explained by the wood cut engraving, there is no occasion for our saying any thing in the way of description; we shall therefore merely call attention to the pleasing combination of the front; and to those no less novel than strikingly happy features, the open staircase galleries, which, with the porch, form the lower centre compartment.

It is true, the idea is borrowed from a similar staircase in the conventual buildings at Canterbury; but this is, we believe, the very first application that has been made of it in modern times; and it is so exceedingly appropriate and characteristic, that the merit of thus transferring to actual purpose what had hitherto been allowed to lie *fallow* for such a length of time, manifests a felicity in appropriation, which certainly is not possessed by every architect. We trust, however, that although it is the first, it will not prove the last modern instance, of staircases leading to the galleries of churches, being so placed, and thus made to conduce very strikingly to exterior design.

We are fully persuaded that staircases so planned would be found to admit of very great diversity; and might with a little study be adapted to the exigencies of every style,—of Grecian no less than of Gothic. Wherefore the gallery staircases in churches should hitherto have been invariably enclosed, it would be difficult to account for, otherwise than by attributing it to the inveteracy of custom, the jealousy of established prejudices, and the timid reluctance to attempt anything that the ignorant may consider odd. It appears to us, that so far from there being anything incongruous or inconvenient in open staircases to such buildings, they recommend themselves by being exclusively adapted to them; and consequently as conferring an appropriate distinction which no other buildings admit of. Staircases of this description would be highly objectionable, and therefore highly absurd, not only in dwelling-houses, but almost every other kind of public buildings except churches and chapels. But there, they no more require to be enclosed or concealed, than does either a porch or portico. Perhaps, indeed, the Church Commissioners might object to such arrangement; it is therefore fortunate that on this occasion Mr. Ferrey has had nothing to do with them, nor been obliged to accommodate his design to the Procrustes bed of their regulations.

Some may probably be of opinion that it would have been better had there been either two turrets, or a central one. Yet in this respect the deviation from perfect symmetry, hardly amounts to a fault; because in very small buildings of this style, perfect regularity is apt to produce an air of formality, and to make the structure appear smaller than it otherwise would. However, we understand that there is some intention of erecting a corresponding turret at the South-West angle of the front, at some future time. The building is to be constructed of rough stone, with its details executed in moulded brick or terra-cotta.

IRON SUSPENSION BRIDGE ACROSS KENMARE SOUND, IRELAND,

DESIGNED BY WILLIAM BALD F.R.S.E.; M.R.I.A. &c. &c. CIVIL ENGINEER.

SUSPENSION BRIDGE OVER KENMARE SOUND.

The situation of the proposed bridge over the Sound of Kenmare, is about three quarters of a mile from the town of Kenmare, in the County of Kerry, and on the South-west coast of Ireland. It is on the new road now in course of construction, between the town of Kenmare, and Glengarriff on Bantry Bay; which when finished, will open to the traveller one of the most beautiful and interesting portions of Ireland. It will pass through four galleries, three of which are already completed; and the remaining one which is the largest, being about two hundred yards long, will be open in November next. The floor of this last tunnel, is elevated one thousand feet above the level of the sea. They all run through strata of solid rock, portions of which are extremely indurated. This road was designed and laid out by Mr. Bald, and it has now nearly reached its completion, under the direction of the Board of Works in Ireland. A further account of it, with its tunnels, bridges, &c. will probably be given hereafter.

The sound of Kenmare, at high water spring tides, is about four hundred and fifty feet wide; and at low water, about one hundred and twenty-five: it varies in depth from twenty-one to twenty-seven feet. Above the town of Kenmare, the estuary extends about a mile and a half; it is about a quarter of a mile broad, and is nearly dry at low water spring tides. Two large rivers flow into it, passing outwards through the Straits or Sound of Kenmare; through which the current runs strong at half tide flood and ebb. Nearly in the centre of this strait, is a rock, called Carrig-buiy, or the yellow rock, on which the tower of suspension is to be built. The bottom and sides of Kenmare Sound consist of transition slate rock, lying in thin beds traversed by veins of quartz, whose dip is nearly vertical. This rock varies very much in its induration, being in some places very soft, and in others very hard. Within a very short distance of the Sound, is to be found compact hard grey limestone in great abundance, in beds of various thickness; it is an excellent material for building, and will be used in constructing the tower of suspension, and the wing walls of the bridge.

The dimensions of the tower of suspension (fig. 3) will be at the base thirty-six feet long by twenty-one feet broad; at the top on each side of the roadway arch, ten feet by seven feet; the total height will be about sixty feet above low water. The elevation of the tower is designed by Mr. Barry. The roadway is to be eighteen feet wide; and the archway through the tower, twelve feet wide. The length of suspended roadway platform on each side of the tower, will be one hundred and sixty-five feet, containing an area of five thousand nine hundred and forty feet. $(165 + 165 \times 18 = 5940.)$ Taking the weight on a superficial foot of the suspended roadway at sixty pounds,* there will be $\left(\frac{5940 \times 60}{2240} = 159\right)$ one hundred and fifty-nine tons on the suspended roadway when loaded.

There are to be four main chains (figs. 5. 6.) on each side, five inches deep by 1.30 inches thick; which will give a sectional area of fifty-two inches $(1.30 \times 5 \times 4 = 26 \times 2 = 52)$. By the experiments of Sir Samuel Brown, Mr. Brunel, and Mr. Telford, the direct cohesion of an iron bar one inch square, was found to be 25, 29, and 31 tons, respectively; but the strength of iron for suspension bridges has usually been taken at only ten tons to one square inch of sectional area. Then, fifty-two square inches would bear five hundred and twenty tons. The tension and weight of the iron in the main chains, &c. are not allowed for; but a sectional area of fifty-two inches in the main chains is quite sufficient to sustain any load that may pass over the suspended roadway. Although a sectional area of fifty-two square inches has been recommended for the main chains, one of forty square inches only is to be adopted.

The main chains at the North end (N, fig. 1) are to pass through tunnels constructed in the middle of the wing walls, and fastened at the ends marked Y, Y (fig. 2); and on the South side (S, fig. 1) tunnels are to be cut into the solid rock, and the ends of the main chains secured at Z Z (fig. 2.) The mode of fastening the chains is shown on a larger scale, in fig. 4; it is the same as that proposed to be adopted by Mr. Brunel at the Clifton Suspension Bridge.

The iron-work of this bridge has been contracted for by Sir Samuel Brown; and the masonry of the tower of suspension and wing walls will be executed by the Board of Works. Mr. Bald estimated this work at about 6,000*l.*; and Sir Samuel Brown offered to complete the whole, including iron and masonry, for 6,150*l.*

Several designs were made by Mr. Bald, and the one contracted for, is not quite so wide as the one here shown; it consists of two semi-catenarian curves, each one hundred and thirty-four feet wide. The design here given is the same except the difference just mentioned; and as before stated, consists of two semi-catenarian curves, each one hundred and sixty-five feet wide. It economizes the masonry to a very great extent, and gives much more water-way to the strong ascending and descending tidal current of the Kenmare estuary.

We have been favoured with an inspection of several designs by Mr. Bald, for the bridge over Kenmare Sound; the first of them consisted of an arch one hundred and thirty feet span; with three other arches, each forty-one feet span. The second design consisted of five arches, each seventy feet span; one of the piers for which was proposed to be built with the diving bell, in a depth of thirty-eight feet of water at high tide. The third consisted of an arch of timber, one hundred and thirty feet span; and four stone arches, each fifty feet span. The fourth design consisted of five arches, each fifty-five feet span; and three Gothic elliptic arches, each thirty-six feet span resting on inverts laid on rubble stone filling; it being proposed to fill the Sound up to the level of low water spring tide.

All these designs have been carefully examined both by Mr. Brunel the engineer of the Thames Tunnel, and by Mr. Alexander Gibb, one of the most skilful and practical bridge builders in the empire; and they have been unanimous in stating their opinion, that on account of the limited funds for this work (6,000*l.*), it would be best to adopt the third design, consisting of one single arch of wood, one hundred and thirty feet span, and four stone arches each fifty feet span.

We should have been very glad to exhibit all these designs; but our columns are so fully occupied, that it is not in our power to do so. The design we have given, is the one approved of by the Board of Works in Ireland; and the Marquis of Lansdowne has in the most liberal manner contributed towards the expense of this most useful public work, a sum of 3,000*l.* We understand that the same nobleman on a former occasion, contributed towards the building of the new bridge of Limerick, a sum of either 6,000*l.* or 10,000*l.*

The various designs which we have mentioned, exhibit great industry and attention on the part of Mr. Bald, in investigating the best and cheapest mode of erecting a bridge over Kenmare Sound. It will be seen that they are of very various materials and constructions. Thus besides accomplishing the immediate object in view, he has drawn the attention of many eminent practical engineers to the subject of the comparative merits of the different plans. Many engineers would, we have no doubt, have proposed bridges for this situation, that would have cost as much as twenty or thirty thousand pounds; thus involving the parties in ruinous expense, or even causing the total abandonment of the intention of erecting a bridge at all.

One more design, much resembling Mr. Bald's first, is given in the following letter from Messrs. John and Thomas Smith of Scotland, architects; which is so full of good sense, that we willingly give it insertion. It is particularly deserving of serious consideration, as being the letter of practical builders, who have executed many bridges so extremely cheap, and with very inferior material,—some of them seventy feet span for a few hundred pounds,*—that their system of bridge building should be every where adopted by working engineers. The abundance of fine flat bedded limestone and slate flags, to be found at Kenmare Sound, offers great facilities for the construction of a bridge there according to the principles of the Messrs. Smith; and it is much to be regretted that any kind of bridge but one of stone, was thought of or adopted. Indeed the slate districts of Ireland generally, offer abundance of excellent material for bridge arching, as recommended and so successfully practised by the Messrs. Smith.

Darwick, November 8, 1837.

Sir,—We received your favour of the 23rd ult. respecting your proposed bridge. We cannot help thinking that under such favourable circumstances for building a stone bridge, you ought never to think of any other. You mention that one arch of 130 feet will be sufficient for waterway; if this is the case would it not be best to build only one arch, and to substitute a mound at the South end, in place of walls or small arches? The mound might be protected from the action of the water, by facing it up on each side with strong pavement to the height of the highest tide; which might be done at a small expense. We have annexed a sketch of such a bridge (fig. 7), which if *economically conducted* we think might be done for somewhere about 2,700*l.*

To execute a chain bridge upon your plan, would require fully as much money. We are, Sir, your most obedient servants,

John and Thomas Smith.

To William Bald, Esq., Engineer, Dublin.

---

* In France, the load on the roadway of suspension bridges is taken at from forty-one to forty-eight pounds per superficial foot.

* A bridge consisting of two arches each 51 ft. span, and one of 26 ft. span, cost 1,300*l.*

Bridge over the River Tweed, two arches of [illegible]½ ft. and one of 26 ft. cost 920*l.*

Bridge over the Hermitage Water in Liddesdale, one rubble arch of [illegible] ft. span, cost 400*l.*

Bridge over the Yarrow, at Yarrow Kirk in Selkirkshire, one arch 63½ ft. span, cost about 360*l.*

The largest arch of rubble whinstone, is built over the Ettrick at Falshope; span 76 ft. 4 in. The estimate for this bridge, the coping of the parapets and the digging of the foundations excepted, was 360*l.*

To these many and various plans, we add one suggestion; that as the tidal estuary of Kenmare Sound extends for nearly two miles above the site of the proposed bridge, it might have been desirable to preserve this navigation to the small coasting masted vessels of the district, by constructing the bridge so as to draw aside and allow them to pass at the deepest part of the sound.

In conclusion, we repeat our expression of regret that a stone bridge has not been adopted, in preference to an iron suspension one. For it would not be liable to those accidents to which works of that kind are exposed; nor would it need that constant attention and those expensive repairs which suspension bridges always require. The insecurity of suspension bridges as exhibited in the many accidents which have taken place; the vibratory motion to which they are subject during gales of wind, and also when heavy loads pass over them, causing a gradual diminution of their strength and stability; ought to determine the engineer never to adopt them under any circumstances, if he possibly can avoid it. Stone bridges decidedly recommend themselves by their strength and durability, and by the circumstance that when properly built they hardly ever cost anything for repairs. In their material and structure, Waterloo and London bridges carry the impress of duration to an almost indefinite length of time; they are besides, magnificent monuments of national glory, the works of a great and a noble minded people, and justly excite the admiration of strangers from all parts of the world, as truly proud monuments of engineering science. In the course of time when the material of the suspension portion of the Menai Bridge, shall have perished, and been consigned to ruin, and worn to dust by the destroying powers of the atmospheric agents; the granite bridges of London and Waterloo will then exist in the same freshness and vigour of duration as that in which travellers now find the ancient granite monuments of Egypt, after a lapse of more than thirty centuries. The sight of these magnificent bridges will always inspire high-minded men with veneration for the genius and talent of Rennie, who planned and executed those noble works; which justly confer celebritry on his name, and will ever rank it high among those which adorn the pages of the history of scientific engineering.

THE VICTORIA HULL STEAM-SHIP.

CORONER'S INQUEST, CONCLUDED.—VERDICT OF THE JURY.

This long-continued inquiry having at length reached its conclusion,—at least in the Coroner's Court; for we see that the proprietors of the Victoria have taken measures to remove it into the Court of Queen's Bench,—we hasten, as far as our limited space will permit, to complete our account of its proceedings.

On Tuesday July 31st, the first witness examined was Mr. Barth, an operative chemist and lecturer, who favoured the jury with an exposition of a theory previously propounded by him on the bursting of boilers, and which he considered applicable to the present case. He attributed the explosion to the decomposition of the steam, and the consequent generation of gases, forming an explosive mixture. For this theory, and the experiments made by Mr. Barth; and for some similar ones also detailed by another witness named Collick, as to the possibility of the water being blown out of the narrow spaces as some imagined it was,—we must refer the curious to the full report in the daily papers.

Several other practical engineers were examined; and the proceedings of the day concluded with the following evidence from Mr. Field,—which we are tempted to give entire.

Mr. Joshua Field, of the firm of Maudslay and Field, engineers and steam-engine makers, of Lambeth, was then sworn, and gave the following evidence:—Having been summoned by a warrant from the coroner for the county of Middlesex to give evidence on the case of the explosion which took place in the Hull steamer, Victoria, on the 14th of June last, I have been on board that vessel to make the examinations necessary to enable me to form a judgment on the matter. On going into the boilers and passing through the flues, I found that the fire-tube of the starboard outside boiler had collapsed to a very great extent, and had become fractured, so as to let the water escape, thus producing the loss of life which is the subject of the present inquiry. As the form and dimensions of these boilers have been accurately described by gentlemen who have been previously examined, it will be unnecessary to detain the jury by adverting to that part of the subject again I shall therefore proceed at once to state my opinion as to the cause of the explosion, and make some remarks as to the construction and arrangement of these boilers. The immediate cause of the accident appears to me to have been, that the strength of the fire tube, from its large diameter and insufficient thickness, was incable of bearing the pressure of steam and water to which it was exposed. I have examined the safety valves, and find that with all the weights on, they were loaded to 13lbs. on the square inch, to which must be added the statical pressure of the water in the boilers, which is equal to about 3lbs. more, acting on the lower part of the tube, about 15 lbs. on the middle, and 14 lbs. on the top; thus taking the mean pressure of 15 lbs. on the square inch, the fire tube, which is 6 feet in diameter and very little more than a quarter of an inch thick, had to sustain a pressure of 2,160 lbs. on every square foot of the surface, and every ring or hoop of it a foot wide had to sustain 17 tons, and on the entire length it had to bear 629 tons; such a pressure could only be sustained so long as the tube retained a perfectly cylindrical figure, and whilst the pressure and strength remained uniform throughout the circle. The pressure, as we have seen above, was not equal by fully two pounds on the square inch. So soon, therefore, as the tube departs from the true cylindrical figure the key of the arch is disturbed, and an immediate collapse takes place. This, I think, is of itself sufficient to account for such a collapse having happened, which may also have been aided by other causes. I could not obtain any certain evidence to the state of the water in the boilers at the time of the accident; but, from an examination of the plates at the fractured part, I should not judge that they had been red hot, and it is clear that the lowest part in which the greatest rupture has taken place would not become red hot until the boiler was entirely empty; and, had this been the case, the upper part must have been red hot for a long time, and would show evidence of that having been the case. The surfaces in the steam chambers, which stand on the boilers from which the steam disengages itself from the water, are divided into twenty compartments, and the total area of them is small compared with the size of the boilers and the quantity of steam rising in them; the ebullition is thereby increased, and this must render the water-line undefined, and make it difficult to keep the feed regular and uniform as in ordinary boilers, where the steam rises from the entire surface. The water spaces, especially at the sides of the fires, are the most contracted I have ever seen, being only 2½ inches; whilst the fireplaces are the largest, being six feet wide by eight feet six inches long. This renders the circulation of the water through these spaces confused and imperfect. The fire, after passing through the large fire-tube above alluded to, is caused to descend through an oblique opening into the space between it and the neighbouring boiler, and passes back the whole length of the boiler between the bottom of the boiler and the bottom of the ship into the chimney, situated at the front, and between the two centre fire-doors. This return flue is formed of plate iron, paved with brick, which arrangement I cannot help pointing out as very dangerous and quite unusual, being very likely to set fire to the vessel. The coals are not stowed in iron cases over the boilers, and detached from them, but lie immediately on the boilers, and consequently for several hundred square feet they are within five or six inches of the most intense part of the flame, insulated, it is true, by the water in a high state of ebullition, when all is going right; but should the water, from any cause become low, these coals would inevitably take fire.

On Tuesday the 14th ult., the only survivor of the men employed about the engine, John Cardinow, the third engineer, for whose recovery the jury had long been waiting, was brought forward to give his evidence. The following extracts seem important, as tending to throw light on the causes of the accident and the practical working of the boilers:—

The feed-cocks were not shut before the collision took place. I shut the feed-cocks off myself at the time, and I'm quite sure they were not turned off before. Neither I nor the other engineers had been pinching the boilers; we had been regulating them. * * He was in the habit, with the other engineers, of regulating the feed; and as the midship boilers would be supplied in their working from the wing boilers, the feed was generally turned nearly off in the midship boilers, whilst they were kept fully open in the wing boilers. This was the case with them when the collision took place, and he turned the feeds off.

Mr. Hall: Was this a regular mode of working boilers?

Witness: Certainly not, but these boilers needed great attention, and required to be worked in this way. * *

Mr. Hall: Did you think there was any danger in working these boilers?

Witness: I was always in bodily fear, but I thought there was no real danger when there was plenty of water in the boilers. The other engineers had the same feeling. We were always examining them, every three minutes at most, and have known the water to lower from the top gauge to the second, in less than five minutes.

There seems to have been some misapprehension respecting the proper height of the water-line; from Mr. Hall's questions, it appeared that he considered it to be, between the 2nd and 3rd gauge cocks; while from Cardinow's answers, it was plain that the actual working line had been understood to be, between the 1st and the 2nd. There was also a strange diversity between the evidence of Mr. Craig, an engineer produced by Mr. Hall, who stated positively that he had been employed by the proprietors for the purpose of instructing the men in the proper feeding of the boilers, and had instructed Cardinow among the rest; and that of Cardinow who stated, "I am sure he gave me no instructions: I do not know what he might have said to the other engineers."

The following extract strongly confirms Mr. Field's opinion of the effect of the narrow water-spaces to be "to render the circulation confused and imperfect:"—

I was never certain how much water there was in the boilers. The solid body of water being nearly as low as the lowest gauge-cock, would bubble up to the highest gauge-cock, and we could not tell where the water was.

Our readers have now before them the evidence of several eminent engineers, complete; fairly selected from the mass accumulated by the jury, and illustrated by a few facts from Cardinow's examination. We have further to record only the verdict, which was delivered at half past one o'clock in the morning of the 15th.

The jury consider that the death of Andrew Brown was accidentally occasioned by the explosion of the boiler on board the Victoria steam-vessel, on the 14th of June last. The jury consider that the construction of the boilers was unsafe, the water spaces too small, and the plates too thin. The jury further consider, that the engineers having no immediate control over the safety-valve in the engine-room is highly reprehensible; and the jury levy a deodand of 1,500*l.* upon the boiler and steam engine of the Victoria.

The inquest having been taken on only one body, the jury had two more sittings, merely as a matter of legal form; which on their account we regret, as their patience had been already but too much tried. And as these additional adjournments, whatever they did in point of law, did nothing further in point of common sense, or of engineering information;—we consider the case complete without any report of them.

THE POLYTECHNIC INSTITUTION, REGENT STREET.

This new Gallery of Science, which was opened on the 6th of August, is an exceedingly interesting establishment; and promises to be one of very great utility, in bringing before the public a variety of ingenious and meritorious inventions, both in the mechanical sciences, and the decorative arts. The curiosity of the most listless can hardly fail to be provoked to examination and inquiry, by the models and specimens of every kind, which are here to be seen. As a very excellent catalogue may be had at the doors, which gives full particulars of all the most remarkable objects, we shall not attempt any enumeration of them, but merely mention one or two of the most striking things in the exhibition.

Foremost in the sorcery of mechanic art, is that of cooking meat at one end of the room by a fire before a reflector at the opposite one,—that is at about the distance of one hundred feet; the heat from the reflector before which the fire is placed, being concentrated by another reflector in the opposite gallery, and thrown upon the meat. These reflectors serve also to convey sound; so that a person who whispers against one of them may be distinctly heard by another, who places his ear against the opposite one.

The process adopted for raising vessels sunk at sea, is also an interesting exhibition; while the diving-bell may not only be seen in operation, but those who like to make the experiment may descend in it. When we were there, many of the company did so, and among the rest some ladies; but how they relished the descent we are unable to say.

Among the works of art, we noticed a plaster statue coated with composition so as to resemble marble; which it imitates so well, that unless the process adds materially to the cost, it is likely to be pretty generally adopted for all kinds of plaster coats. There are also several beautiful specimens of tables inlaid with different coloured woods, others of inlaid flooring or parquetry. Among specimens of this class are some very admirable ones of paper for rooms, in imitation of the most delicate veined marbles of different colours. We only regretted that a practical application of them for decorative purposes, had not been shown, by introducing ornamental surfaces of this kind into some of the panels and compartments of the architecture of the room itself; more especially as a little ornamental colouring would greatly aid the general effect.

The large Hall or Museum, to which there is an ascent from the entrance hall by a short flight of steps, is 120 feet by 40, and 40 high; and lighted very much after the manner of the Pantheon Bazaar, by a series of fourteen windows on each side, in the curve of the ceiling. The covered part of the latter, is divided by bands into 21 large square compartments, viz., 7 in its length, and 3 in its breadth. There is also a semicircular window at each end, that at the East opening into an upper room appropriated as a bazaar for the sale of fancy articles. The staircase is simple, but of very pleasing character. This leads to a spacious semicircular theatre in the upper part of the front building, where we behold the wonders of the Hydro-oxygen Microscope.

OBSERVATIONS ON ROMAN CEMENT.

Sir,—Your excellent correspondent C. L. O., in his useful article on "Building Materials," inserted in your last number (p. 244), has fallen into some errors in his remarks on cement. His observation that "the article commonly called Roman cement, which for many years was extensively used throughout the kingdom, is now partially superseded by the introduction of other substances," is totally incorrect; its use is at the present moment at least ten times greater,—perhaps fifty fold greater,—than at any former period, and there is no other substance in any degree worth notice used in competition with it.

Your correspondent is mistaken in asserting that the "blue lias when used as stucco is certainly superior to Roman cement," excepting that its colour is somewhat better. All he says in its favour is erroneous; and so is his observation, that "Roman cement is never so good as when it was first introduced." If he will apply to the original patentees, and will pay the price demanded (considerably less than formerly), he may obtain Roman cement of as good quality as ever it was; but the real truth is, that great quantities of the cement now offered for sale, do not contain a particle of Sheppy stone, of which it was originally wholly manufactured; at the same time it should be mentioned that all the stone is not good that comes from that island. The Sheppy stone varies in quality, as much as your correspondent justly states the Roman cement does both in quality and price. The genuine Roman cement is not always very dark in its colour, as C. L. O. states it to be; indeed it is generally much lighter than the kind manufactured from Harwich and other stone; and it is therefore the practice of some manufacturers to mix Swalecliff and other light-coloured stone with the Harwich stone, to give that cement the lighter colour of the genuine cement. They thus depreciate the quality of the cement made from the Harwich stone, as the Swalecliff stone although it lightens the colour of the cement, and causes it to set quickly, as the genuine cement does, has the quality also of "giving" after it has set, as it is technically called; that is to say, becoming loose and soft, and falling off. The genuine cement is in many instances used without sand, particularly in tide and other aquatic work. It was so used lately in repairing the London Docks, and is so at the present time in the Tunnel. It is seldom employed as a stucco for facing buildings, with less than three parts of sand to one of cement; in which case, if laid on by a skilful workman, it is not "very liable to crack in drying." A skilful workman is very essential to the successful application of the genuine cement.

Your correspondent says that except when mixed with great care, it can seldom be made to bear a very smooth face; the smoothness of its surface, when used as a stucco, depends more upon the texture of the sand, and the care exercised in hand-floating it while setting, than the mixing of it.

Your correspondent says that Atkinson's cement is very similar in quality to Roman cement. The following is the analysis of both, by Sir Humphry Davy:—

Parker's Cement. 100 grains contain		Atkinson's Cement. 100 grains contain	
Silex	22	Silex	21
Alumina	9	Alumina	7·5
Oxide of Iron and Manganese	13	Oxide of Iron and Manganese	13·5
Carbonate of Lime	55	Carbonate of Lime	55
	99		97
Loss by heating	3·25	Loss by heating	3·32
	102·25		100·82

Yours, &c.,

London, 25th July, 1838. H. N.

THE WELLINGTON CHAPEL; REPLY TO J. H.'s CRITIQUE.

Sir,—Your correspondent J. H. has been pleased to notice the Wellington Chapel in the last month's Journal (p. 247); and to deprecate as much as lay in the power of an uninformed critic the abilities of the unknown artist, or whatever he may choose to designate him, who designed it. That the building is in strict conformity with the models of Greece, I do not pretend to assert; the deviations may be great, and some of them reprehensible. At the same time a barrack is not a palace; nor a barrack chapel a Parthenon;—and I must think it somewhat illiberal in a person so highly gifted with the capacities of architectural judgment as Mr. J. H. would appear to be, to pour his execrations upon the efforts of an individual against whom he can have no

direct animosity, and with whom he professes to have no acquaintance, as being employed in the execution of a building which is far superior to those generally constructed in barracks,—though not a copy of the antique, or the beau ideal of Mr. J. H.'s imaginations.

It may be, that the person employed, laboured under disadvantages to which Mr. J. H. may thank Heaven that he has been a stranger; and perhaps he had difficulties of situation to encounter which Mr. J. H. would have combated with less spirit. Be this as it may, the building is no discredit to its author; nor can I think that a Smirke, a Barry, or a Cockerill, or even an Ictinus or a Callicrates (with whose names Mr. J. H., "unknown to fame," seems so slavishly familiar), with all their acquired reputation and ambition, would stoop to envy the celebrity that might have been acquired by a less humble, but more authorized professor of the art, in the execution of such a building and for such a purpose. Far be it from me to dispute the right of critical observation which Mr. J. H. claims to himself; had he allowed the venom of his indignation to flow only on the walls of the chapel, I should not have troubled myself by noticing his remarks: but when he would level his sarcasm rather against the "uneducated" author, than against the public building which he magniloquently claims a "public right" to judge, I must step forward and ask his criticismship to forbear. By what right of profession, of celebrity, or of education, does Mr. J. H. arrogate to himself the denunciation of an individual whom he supposes not to be possessed of these indispensable distinctions? Does Mr. J. H. imagine, in the height of his architectural conceits, that no one but he who has been indentured in an architect's office can possibly become an architect?—that none but such as have mis spent six or seven years of valuable time in contemplating a drawing-board, and then wandering in search of the Pantheon or the Acropolis, can make a design? I cannot suppose him so senseless; nor would I insult his understanding, by telling him that it is possible for genius to raise itself by its own exertions; or that there really have been instances of the kind.

For my own part, I am an ignorant, unprofessional, and unlettered man, Mr. Editor; but I still claim the use of your Journal as an arena in which Truth shall be properly asserted; where works of architecture may be honestly criticised, but not characters aspersed; where talent, however humble and uneducated, may obtain an equitable sentence; but where vain or bigotted presumption shall meet with fitting castigation, and where personal calumny or detraction shall never usurp the seat of calm and dispassionate criticism.

Yours, &c.,

July 27th, 1838. A SUBSCRIBER.

[In compliance with the request of our correspondent, we insert his letter at the earliest opportunity; though we acknowledge that in this case as in numberless others that are constantly coming before us, we think the complaining party would do better to keep silence, unless he is prepared to overthrow the criticism of which he complains. We have carefully read over again J. H.'s critique on the Wellington Chapel; and we really do not see that our "Subscriber" has any just cause of complaint. J. H. points out certain deviations from classical authorities;—our correspondent "does not pretend to assert that the building is in strict conformity with the models of Greece." J. H., who appears to be altogether devoted to classical models, conceives that deviations such as those pointed out, could not have proceeded from a regularly educated person; our correspondent confesses to being "an ignorant, unprofessional, and unlettered man," though we must acknowledge the style of his letter compels us to take his assertion not quite literally. We think our correspondent would have done better, under the circumstances, either to be silent, or to meet J. H.'s criticism by a discussion of the principles on which it is based; by a free and full inquiry into the necessity or desirableness of using classical models for modern architecture, and the extent to which they may or must be modified in this adaptation,—a question on both sides of which there is a good deal to be said.—Ed.]

REMARKS ON STEAM ENGINE FURNACES BURNING THEIR OWN SMOKE.

Sir,—I beg to recommend to your consideration, a subject for the Journal, viz., the consuming of the smoke of steam engine furnaces. It is one which, from their great number throughout the kingdom, is next in importance to that of railways. Besides which, it is still new and fresh, which the other is not; for although some trials have been made at manufactories to burn the smoke, they have not succeeded; and the attempt is now given up, or rather not thought of, the thing being deemed impracticable. Instead of it, huge brick chimneys are erected; but the only effect of these, though not so intended, is to carry the smoke away from the manufactories, to places in their vicinity, which otherwise would not be annoyed, except from such unsightly objects being continually in view, rendered doubly offensive from being surmounted with a mass of smoke.

In Blackwood's magazine for December last, page 806, mention is made of a new and successful invention by a Mr. Coad, for burning smoke; and in the Journal No. VII, page 168, you give an account of the trial of a smoke consumer invented by Chanter and Gray, and speak of it in favourable terms. If these, or either of them, or any other, be really good and useful inventions, answering the purpose professed, it is to be regretted that they are not brought prominently and repeatedly to the notice of the public, and manufacturers made aware that in fact the smoke may be consumed.

It occurs to me that for this purpose the Journal would be a fit and admirable vehicle, and would be repaid for its services by increased popularity and circulation; which is the reason of my addressing this letter to you. It is understood that if the smoke could be consumed, there would be a great saving in fuel; and as this is the consideration that would chiefly weigh with manufacturers in inducing them to make trial of the invention, the most effectual mode of informing and assuring them that it will be for their interest to do so, would be for the patentees (you and they first communicating and agreeing), to insert in the Journal from time to time, besides occasional articles, the names of manufacturers who have availed themselves of the invention, with the result as to the smoke being either totally or nearly consumed, and the saving of fuel, labour, &c.; the mention also of the patentees' charge, the expense of erection, &c. would be convenient information. This matter is clearly within the scope of the Journal, indeed so appropriate, and interesting in the probable result, that you ought to take an especial charge of it; and if it should thus come to pass, that gradually, the smoke should be consumed, and that chief of nuisances removed, an immense benefit would be conferred on the country, accompanied, it need not be doubted, with corresponding prosperity to the Journal. I hope my suggestions will be well received, and shall be glad if they are adopted.

Yours, &c. A SUBSCRIBER.

Glasgow, July 23rd, 1838.

[We willingly accede to our correspondent's proposal, and shall be happy to receive communications on this, as on other subjects of importance and interest. As however we consider it by no means a "new and fresh" subject, we beg to be understood as wishing rather for particulars of the *actual working* of apparatus for consuming smoke, than for accounts of untried and half perfected designs for this end. We remember some few years ago, finding the general feeling of the manufacturers in Lancashire strongly against the possibility of effecting the object, desirable as they admitted it to be. And this seemed to arise from the failure of attempts that had lately been made in several instances to introduce some patent contrivance;—but whose it was, we do not remember. At the Eagle foundry in Birmingham, we saw about two years since, an apparatus which had been in use most effectively, as the proprietors stated, for many years. We certainly watched in vain for any volume of smoke from the chimney, and saw nothing but a very small quantity of very inoffensive vapour. The apparatus consists of a revolving furnace, to which coal is constantly supplied in small quantities by a hopper, the engine regulating the supply. We were informed that the plan is decidedly economical; the coal not only may, but *must* be small; and the machinery needs little repair. The proprietors had furnished their contrivance to various persons in different parts of the country; and,—what appears the best test of their success,—were frequently receiving orders from the same places for more. There are probably many other inventions in use in one place or other; we just mention this which we happen to remember, as our contribution towards the fulfilment of our correspondent's wish. We hope our readers will do the same;—with this difference however, that they, describing things under their own eyes, will be able to give us *exact particulars* of the construction of the apparatus where it is successful, and the effect produced, both in saving fuel, and in preventing smoke. Various attempts are also making to introduce the anthracite coal for consumption in engine furnaces; and as this coal consists almost entirely of pure carbon, it evolves no smoke worth notice. Accurate reports of such experiments would, we doubt not, be interesting to our readers, and consequently acceptable to ourselves.—Ed.]

SUGGESTIONS FOR SUPPLYING TOWNS WITH SEA WATER.

Sir,—It has occurred to me that towns on the coast, and others not far inland, might be profitably supplied with sea-water by any company that was disposed. Taking this port as an example;—if water works were established near the river, two or three reservoirs would I think suffice to raise the supply to Olive Mount, and thence it would naturally fall to Manchester and intermediate places. For a small remuneration, the Railway company would no doubt allow the pipes to be laid on the side of the line, where they would be undisturbed, and could at any time be repaired with little inconvenience.

The advantages to be derived from such a scheme are obviously great, as through its adoption large swimming baths might be established in country places (as well as in the towns), and persons sojourning there would combine the advantages of sea-bathing with rural retirement.

In places thus supplied, invalids might enjoy on *their own* premises, without risk of cold or other drawback, a warm salt-water bath, sometimes so essential to their recovery.

This plan would not prove injurious to any "watering places;" as those who would principally have recourse to water thus supplied, would be that numerous class who have limited incomes, or are prevented by their avocations from leaving home. The wealthy and those accustomed to annual or biennial trips to the sea side would scarcely yield the pleasure of bathing in the "wide unbounded sea," or of inhaling its pure fresh breeze. K. C.

Liverpool, July 8, 1838.

AMERICAN LAWS FOR THE SECURITY OF STEAM BOILERS.

An Act authorising the appointment of persons, to test the usefulness of inventions to improve and render safe the boilers of steam-engines against explosions.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that the President of the United States be, and he hereby is, authorised to appoint three persons, one of whom at least shall be a man of experience and practical knowledge in the construc-

tion and use of the steam-engine, and the others, by reason of their attainments and science, shall be competent judges of the usefulness of any invention designed to detect the causes of explosion in the boilers; which said persons shall jointly examine any inventions made for the purpose of detecting the cause and preventing the explosion of boilers, that shall be presented for their consideration; and, if any one or more of such inventions or discoveries justify, in their judgment, the experiment, and the inventor desires that his invention shall be subjected to the test, then the said persons may proceed and order such preparations to be made, and such experiments to be tried as, in their judgment, may be necessary to determine the character and usefulness of any such invention.

Sec. 2. And be it further enacted, that the said board shall give notice of the time and place of their meeting to examine such inventions; and shall direct the preparations to be made, and the experiments to be tried, at such place as they shall deem most suitable and convenient for the purpose; and shall make full report of their doings to Congress at their next session.

Sec. 3. And be it further enacted, that to carry into effect the foregoing objects, there be, and hereby is, appropriated, out of any money in the Treasury not otherwise appropriated, the sum of six thousand dollars; and so much thereof as shall be necessary for the above purposes shall be subject to the order of the said board, and to defray such expenses as shall be incurred by their direction, including the sum of three hundred dollars to each, for his personal service and expenses: provided, however, and their accounts shall be settled at the Treasury, in the same manner as those of other public agents.

Approved, June 28th, 1838. M. VAN BUREN.

The New York papers inform us that the bill for preserving the lives of passengers in steam-boats, has passed both Houses of Congress. It declares an explosion or other disaster to be *prima facie* evidence of negligence, and sufficient for conviction.

TRIALS OF ANTHRACITE COAL FOR LOCOMOTIVE ENGINES.

We understand that on Friday the 3rd ult., a trial of the applicability of anthracite coal, as a fuel for locomotive engines, was made on the Liverpool and Manchester Railway, under the superintendence of Mr. Woods, the engineer of that line, and with the approbation of the board of directors. Mr. E. O. Manby, an engineer connected with the South Wales anthracite district, who has devoted his attention most successfully to the introduction of this fuel, was present, and assisted in the trial.

The engine employed was the Vulcan, one of the smaller engines, used for conveying goods. The general result of the experiment was highly satisfactory. In the first instance, the engine ran out without a load about six miles; and the coal was found to do very good duty, without any difficulty being experienced, either with the tubes or in getting up the fires. It was noticed that the fuel burnt nearly without dust from the chimney, and entirely without smoke. The engine brought back a load of coal waggons from the Huyton colliery, and acquired a speed, thus loaded, of 21 miles an hour, which is about the duty of the Vulcan.

Another trial was made in the evening, with the same engine, for the whole distance to Manchester, taking five loaded waggons. The journey was performed in one hour and 29 minutes. The consumption of anthracite was only 5½ cwt., although a large portion was wasted from the fire bars being too wide apart for the economical use of this fuel. The engine would have used upwards of 7½ cwt. of coke for the same journey, and for the same load. We regard the success of this trial as likely to prove, in its result, a most important public benefit. The price of coke, as the demand for it for use in locomotive engines on railways has extended, has increased in some places almost 50 per cent.; and in districts which produce no coal, this enhanced cost of coke will be seriously prejudicial to the success of railway undertakings. If anthracite can be generally applied in locomotive engines, we are given to understand that a saving of 30 or 40 per cent., in cost and quality, will be effected.

The application of anthracite to marine engines, is the next object most deserving the attention of practical men. The journalists of the United States appear to claim for their country almost the exclusive production of this invaluable fuel, which is destined to play so great a part in the iron manufacture, in railway locomotion, and in steam navigation; but the Western part of the South Wales coal field, with reference to which Liverpool is, geographically, so favourably situated, contains stores of anthracite of much superior quality to those specimens of American which we have seen, and can produce it at a much smaller cost.—*Liverpool Albion.*

[We have been favoured with a few particulars of three trials of anthracite coal on the London and Birmingham line, which have been made during the past month. Their result has been the reverse of satisfactory. The coal it seems, flies to pieces from the heat, and thus falls into a close layer on the fire bars, greatly obstructing the draught. Coke on the contrary, from its light and open texture, and the large irregularly shaped masses in which it comes from the oven, allows of a free draught, though it generally lies on the bars to the thickness of twelve inches. The result was, that in each of the three trials, the engine came to a stand at the same spot, which was a steep inclination, when other fuel had to be used. But it appears that the anthracite does very well in conjunction with coke, though not alone. We are informed that the coal used in these experiments was similar to that tried on the Liverpool and Manchester line, though from a different mine. And it is said that the coal used by Mr. Manby had been previously coked; but to what extent does not appear.—Ed. C. E. and A. Journal.]

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

REPORT OF PAPERS READ AND PROCEEDINGS, SESSION 1838.

(*Continued from page 292.*)

On Huddart's Rope Machinery. By George Drysdale Dempsey.

The above communication on the improvements in rope manufacture, introduced by the late Captain Huddart, contains a general account of the successive improvements introduced, and a description of the machinery invented by that celebrated man and erected at Limehouse.

It is accompanied by ten sheets of drawings of the machinery.

The preceding communication having been laid before the meeting, a discussion took place on the relative strength of the cables of Huddart's and the ordinary manufacture. The strength of two-inch rope of Huddart's, when compared with that of the ordinary manufacture, is as 8 to 5¼. The increase in strength was greater for large ropes than for small. The best test of the wear of ropes, are those of mines. A five-inch Huddart's rope has been found to last twice as long as a six-inch rope; the weight of the former is much less, consequently there is a great saving in power as well as in durability. It was stated that there was danger of the tar being of such a temperature as to char the yarns; tar of the temperature of boiling water was the best.

On Huddart's Rope Machinery. By E. Birch.

In this communication, the author has described the general mode of manufacture, prior to the improvements introduced by Captain Huddart, and the establishment of the works at Limehouse.

It is accompanied by fifteen sheets of drawings of the machinery.

On the relative Heating Powers of Coke and Coal in Melting Glass. By Apsley Pellatt, Assoc. Inst. C.E.

The object of this paper is to confirm some statements of Mr. Parkes,* as to the calorific power of coke and coal, from experience of the author's in melting glass. The great loss of heat arising from the flame and unconsumed gaseous portions of the fuel being driven up the flues, when the furnaces are heated by coal, and the fact that coke succeeds better than coal in annealing glass, determined the author to persevere for a month in heating the furnaces with coke, and to compare the result with those obtained when the best coal was employed.

The construction of the furnace, and the arrangement of the pots and flues are described. The furnace is somewhat reverberatory, being between an air furnace and an oven; the smoke and flame not escaping at the top, but being drawn to flues betwixt the pots, which are set round in a circle. For the purpose of obtaining sufficient heat about the points and sides of the pots, there are small holes, called "bye-holes," through which the flames should play outward in a length of 5 or 8 inches. The healthful action of the furnace is indicated by the length of the flame issuing from the bye-holes and tops of the flues. Great care is requisite in regulating the supply of air, too much air endangering the pots, too little checking the heat of the furnace. The bars were obliged to be placed at 2 inches apart instead of 1½; the greater concentrated heat of the coke not only requiring more air, but having a tendency to melt the bars; lumps of fire-brick also were thrown in, to supply the deficiency of clinkers. To make, however, the flues and bye-holes draw well, it was necessary to use ⅕th of screened coals with ⅘ths of good coke by measure. The following is the result:—For nine months, the consumption of coals for a 7 pot furnace was 18 tons per week. For four months, on the new system, the consumption was 10½ tons of coke, and 5 tons of screened coals per week. Deducting then these 5 tons, it appears that 10½ tons of coke are of the same value as 13 tons of coal, or there is a saving of near 20 per cent. in the weight of fuel, and a superiority of 25 per cent. in the heating power of coke above that of coal. Considerable advantage is also derived from the saving of the pots, and in other incidents peculiar to the manufacture of glass.

Mr. Parkes observed that the preceding statements had more than confirmed his results. From the statements of Mr. Pambour, on whose data his calculations had been founded, it appeared that gas coke was inferior to Worsley coke by 12½ per cent.; in his reasonings he had allowed 20 per cent. as the difference betwixt good coke and coal; but according to the results given by Mr. Pellatt, the allowance ought to be 32½ per cent. He was of opinion that the advantage to be ascribed to the screenings was partly chemical and partly mechanical. The coal would fill up the interstices of the coke, and prevent the air from escaping unconsumed.

Mr. Pellat remarked, that the safety of the pots was a very important consideration. By the terms hard and soft coke, he understood foundry and gas coke; the former gave a much more intense heat, and lasted longer. The coke he had used was gas coke, and about 14 cwt. to the chaldron. Mr. Fox stated that the coke in use on the London and Birmingham Railway, is about the same weight. It was stated, that coal which lost ⅓th in weight gained ⅓th in bulk by coking.

* See Minutes, p. 170, Journal No. VII.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

[The following minutes of Proceedings were inadvertently omitted in the last number of the Journal.—Ed.]

At an Ordinary General Meeting of the Members, held on Monday, the 25th of June, 1838.

P. F. Robinson, Esq., V.P., in the Chair.

The Secretary communicated that the Council had requested his Lordship the President, to apply for her Majesty's permission to allow Mr. Behnes a sitting for the purpose of taking a bust of the Queen, to be deposited in the Institute as Patroness; and his Lordship's letter on the subject to the Marquess of Lansdowne, was read, together with an answer communicating her Majesty's gracious consent to the request.

A letter was read from Sir Alexander Grant, acknowledging with thanks the invitation of the Institute, and presenting to the Library a copy of Durand's Parallèle des Edifices anciens et modernes.

The following donations were also received: Dr. Granville; Copy of his work on the Spas of Germany; Guide to St. Petersburgh, 2 vols. 8vo.; and plans and elevations of Hospitals and Scientific Institutions in Paris, 31 plates.—S. Whitwell, Esq.; Copy of his pamphlet on Warming and Ventilating.—P. Hardwick, V.P.; Reports of the Surveyor General of H.M. Land Revenue, 2 vols. folio; Reports of Commissioners of Public Records, 2 vols. folio.—J. Foulston, Fellow; Model of Scaffold for erecting the Devonport Memorial; and various specimens of granites and slates.—W. R. Billings, Associate; Copy of his work on the Temple Church.—Monsieur Suys, Corresponding Member; Plan du Palais de Justice, Bruxelles.—G. B. Webb, Associate; Specimen of Asphaltic pitch from the banks of the Euphrates.

Dr. Granville explained the nature of the series of views presented by him.

Mr. Foulston described the nature of the specimens, and the construction of the model presented by him.

Mr. Griffiths proceeded with his lectures on Chemistry as applied to construction;—subject, Marbles, Lime-stone, Mortars, Cements.

At an Ordinary General Meeting of the Members, held on Monday, the 9th of July, 1838.

P. F. Robinson, Esq., V.P., in the Chair.

The following gentlemen were elected:—As Fellow, Archibald Simpson, Architect, of Aberdeen;—as Associates, George Vulliamy, Architect, of Pall-mall; H. G. Atkinson, Architect, of Upper Gloster-place, R.P.

The following donations were received:—Society of Arts; Copy of their Transactions, Part II. of vol. 51.—Heddon Stone Company; three specimens of their stone.—Lieut. C. T. Hill, R.N., and W. S. Inman, Fellow; Plan of Paris.—T. L. Donaldson, Hon. Sec.; Bill of the Westminster Improvement Company.—G. Godwin, jun., Associate; No. 19, of his work on the Churches of London; and Nos. 1 and 2 of a series of papers on Construction, commenced in London's Architectural Magazine.

A summary of the first three numbers of the Ephemeris of the Archæological Society of Athens, was read, translated from the original by Lieut.-Col. Leake.

Mr. Crace exhibited a fac-simile of the Plate Armour of the Duc de Guise. It was made in France, of a material called Carton Pierre,—a composition which presents a beautifully sharp and even surface. It is then prepared and finished by a particular process, which renders it a perfect imitation of iron or steel. Mr. Crace likewise stated that he has embossed suits of richer description, and also shields, arms, &c. And further, that having discovered the process before mentioned, it is his intention to manufacture these objects in England.

Mr. Griffiths read the fourth paper of his series;—subject, Paints, Varnishes, &c.

THE ROYAL INSTITUTE OF BRITISH ARCHITECTS, AND THE ARCHITECTURAL SOCIETY.

FACTS CONNECTED WITH THE ATTEMPT RECENTLY MADE TO EFFECT THE JUNCTION OF THE TWO SOCIETIES.

Some of the principal members of these two societies, have long felt how desirable it would be, to concentrate the exertions made by the two bodies for the promotion of the art. Sir John Soane, when he made his munificent donation to these societies, expressed a strong wish that he might have been able to unite in one, the gift which he presented to them severally; and his wish has been responded to by several of the leading members both of the Royal Institute of British Architects, and of the Architectural Society.

A special general meeting of the latter, was held on the 3d of July, at which the following resolution was passed:—

"That a junction of the two Architectural Societies would, if formed upon principles of mutual concession, be highly advantageous to the profession; and that a committee of five members be forthwith appointed, to confer with a similar number of gentlemen on the part of the Royal Institute of British Architects, and to report the result of such conference to the Society at large, on or before the 1st of August following."

In pursuance of the above resolution, the following members were the same evening appointed—Mr. W. B. Clarke, President; Mr. Barnes, Mr. Wyatt, Mr. Moore, Mr. Crake, Mr. Ferrey.

This having been communicated to the Council of the Royal Institute of British Architects, Messrs. Barry, Hardwick, and Robinson, Vice Presidents, and Messrs. Kendall, Taylor, and Donaldson, were appointed to confer with the Committee of the Architectural Society.

These gentlemen accordingly had two meetings, and mutually agreed to the following scheme for the union of the two Societies:—

1. The Members of the Architectural Society, who have been in practice seven years, to join the Royal Institute of British Architects as Fellows.

2. Those who have been in practice five years, to enter in a new class, to be expressly constituted, under the title of "Associated Fellows," and to pay annually three guineas.

3. The Associated Fellows to have all the privileges of Fellows, except voting and eligibility to offices.

4. The Members elected into the class of "Associated Fellows," become by *right*, and without ballot, Fellows, upon announcing their intention to join such class, at the expiration of their having been in practice seven years; and to pay two guineas, to make their contribution on admission five guineas, equal to that paid by the Fellows of the Royal Institute of British Architects.

5. The class of Associated Fellows to cease at the end of two years.

6. Those under five years, to join as Associates, and to pay annually two guineas.

7. A permanent class to be created, called the "Students' Class," at a subscription of one guinea per annum, to receive the students of the Architectural Society.

8. Their privilege, to attend all Ordinary Meetings and Lectures.

9. The members of the Architectural Society to be elected without ballot in their respective classes, as conforming to paragraph 21 of Section IV. of the Bye-laws of this Institute, upon the introduction of the Council.

10. The several members so joining, to sign the Declaration of the Royal Institute of British Architects.

11. The President and one other Member (or any two) of the Architectural Society, to be recommended by the Council of the Royal Institute of British Architects for election forthwith, as members of the Council.

12. The members of the Architectural Society, who join the Royal Institute of British Architects, to make over to the Royal Institute of British Architects all their shares in the funded property, books, casts, prints, drawings, furniture, and other effects of the Architectural Society, and the same to fall into and become an integral part of the property of the Corporation.

The Council of the Royal Institute of British Architects recommended to the adoption of the members, the several propositions contained in the preceding scheme; feeling confident that, should their hopes have been realized, of an union of the two bodies, not only would the Institute have been benefitted by such an accession, but the purposes for which both Societies were originally established, might have been more efficiently carried into effect. The adoption of these propositions involved the suspension, for a short period, of some of the Bye-laws of the Institute; but the Council considered that, as such suspension would not have been operative upon any regulation connected with the character and respectability of practice in the members, the temporary departure from the established regulation would have been amply compensated by the great good, which would have been effected by the concentration in one Body of the exertions of all the members of the Profession.

This scheme was confirmed by a special general meeting of the Fellows of the Institute, on the 31st of July; and on the 1st of August, the Architectural Society decided at a special meeting, that it would not be desirable that a junction of the two Architectural Societies should be formed upon the terms contained in the scheme. On the same evening, Messrs. Walker, Ferrey, Moore, Wright, Bury, Lee, Parish, Woodthorpe, Brandon, and Flower, ceased to be members; Messrs Johnson and Watson have since withdrawn: and we understand that several others have expressed their intention to resign. The unforeseen decision of the Architectural Society arose, it would appear, from the absence of several supporters of the scheme abroad or in the country, the badness of the weather in the evening, and the general confident anticipation that the equity of the propositions would have disarmed opposition. The result, however, will be different from that expected by the opponents of the measure, who mustered in strong numbers; the Architectural Society thus deprived of its chief members, we fear may be considered as so much crippled in its usefulness, as to be virtually dissolved.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

This learned body having fixed upon Newcastle-on-Tyne as the place of their eighth meeting, the various members began to assemble on Thursday and Friday the 16th and 17th ult.; and on Saturday, the meeting of the General Committee was held. The newspaper reports speak in high terms of the excellence of the arrangements made; and give most encouraging accounts of the prosperity of the Association.

The business of the Sections commenced on Monday the 20th. It is our intention to give our readers such information as comes within our province, respecting the proceedings. We regret however that the press of matter which has filled our columns, renders it impossible in the present number to do more than record the subjects of the proceedings of Section G, that of Mechanical Science.

Monday, August 20th. On a new Day and Night Telegraph, by Joseph Garnett. On Isometrical Drawing, by Thomas Sopwith. Description of an improved method of constructing large Secretaires and Writing-tables, by Thomas Sopwith. On the power of economising and regulating Heat for Domestic purposes, by George Webb Hall. Notices on the Resistance of Water, by John Scott Russell. On the principles of Oblique Bridges, by Peter Nicholson. Remarks on the material and mechanical construction of

Steam Boilers, by W. Greener. And a communication from Mr. Maule, on a substitute for the Forcing-pump in supplying Steam Boilers.

Tuesday, August 21st. A new Rotatory Steam-engine, by S. Rowley. Report on Railway Constants, by Dr. Lardner.

In the evening of the same day, an interesting meeting was held at the Model room of the Association. Professor Babbage, the president of the Section of Mechanical Science, illustrated by reference to models and diagrams the arts of Engraving on copper and wood: exhibiting also specimens of the art of printing in colours from wood blocks, communicated by Mr. Knight the publisher. The Rev. Dr. Robinson of Armagh explained the construction of the wooden Viaduct over the Ouseburn, as exhibited in a model. Professor Willis exhibited and explained a model of a new Locomotive Engine.

Wednesday, August 22nd. On the improved Construction of Railways, by Mr. J. R. Peele. The construction of Railway upper works, by Mr. Mosley. A new mode of pumping Leaky Vessels, by Dr. Dalziell. On a new dry Gas Meter, by Mr. Saunders. On a Machine for raising water, or a Hydraulic Belt, by Mr. Hall. On a new Steam-engine Boiler, by Mr. Price. On the construction of Geological Models, and on an improved Levelling Stave, by Mr. Sopwith.

Thursday, August 23rd. Professor Phillips described an Odontograph, or instrument for setting out the teeth of wheels, illustrated by a model. Mr. Lang exhibited models of a round headed Rudder for Ships, and a Tube Scuttle. Dr. Lardner spoke at considerable length on Steam Navigation; and described the principle of his self recording Steam Journal, of which he also exhibited a model. Mr. Russel made some observations on the present state of Steam Navigation. The Section then adjourned to Saturday morning.

LAW PROCEEDINGS.

[The important case, Ranger *v.* the Great Western Railway Company, is necessarily deferred to a future number.]

ROLLS COURT, CHANCERY LANE, *July 4th.*

THE ATTORNEY GENERAL, ON THE RELATION OF JEREMIAH HAMMOND *v.* GREAT WESTERN RAILWAY COMPANY.

Mr. Kindersley applied to the court for an injunction to restrain the defendant from making a bridge, along which the Great Western Railway was to pass, over a certain aqueduct or canal, which had been constructed under an act of Parliament passed in the 43rd year of the reign of his late Majesty George the Third, for the purpose of increasing the navigation to the Bristol docks, as well as for a feeder to the dock in which the vessels float.

Mr. Pemberton observed that the object of the canal was twofold—the one to increase the trade, and the other to cleanse the docks; the present application was against constructing the bridge in a particular way. The members of the dock company were interested in the canal as well as this undertaking, and he thought they were necessary parties. He also thought that it would be necessary for the defendants to answer the affidavits, which, though they had been made some time, had not been filed till the 27th of June.

The motion was then allowed to stand over.

July 19th.

Mr. Kindersley proceeded in this motion, on the part of the relators. It appeared from his statement that the proposed bridge crossed the cut at a very oblique angle; and that the cut was at that point 64 feet wide. The Railway Company proposed to construct a bridge of three arches, 16, 27, and 16 feet wide respectively, the middle one forming the water-way, and the towing path passing through one of the side arches. The Canal Company insisted on having their towing path preserved alongside the cut, without the intervention of the pier; and demanded for this purpose an arch 31 feet wide, 24 for water-way, and 7 for towing path. The Railway Company refused to accede to the demand, except on condition of the Canal Company bearing the additional cost of their own plan.

Mr. Pemberton, on behalf of the Railway Company, stated that there were 28 bridges between Oxford and Datchet, all of which, except those on the suspension principle, had the towing path separated from the water-way.

Mr. Kindersley replied, that if Mr. Brunel had not stopped at Datchet, but come down to the bridges at Staines, Walton, Kingston, and Richmond, he would have found none of the towing paths separated from the river.

Lord Langdale said he could not concur in the inference, that because old bridges were built in an inconvenient manner, the present parties had a right to do the same. His Lordship ultimately ordered the case to stand over; and an experiment to be made meanwhile, whether the existing coffer-dam did impede the navigation, as it was alleged that the pier would when the bridge was completed; and whether it was feasible without a towing-rope to get the barge through the water-way.

July 27th.

Mr. Kindersley stated that the experiment ordered had been made, and was proceeding with some remarks upon it, when he was interrupted by

Mr. Pemberton, who offered, on the part of the Railway Company, to construct an arch sufficiently large to allow of an eight foot towing path, without contracting the water-way. Or they would even make under the arch a road-way for horses, supported on iron piles; but this would narrow the water-way at least six feet.

The motion was ordered to stand over for a week, to allow time for an arrangement between the parties.

August 6th.

Mr. Kindersley, with whom was Mr. Richards, stated that the Railway Company had offered to make a towing path five feet wide under the arch over the water-way of the feeder to the Bristol Floating Dock, which was to be protected from the water by a rail of two feet nine inches high. The proposal, however, was not considered sufficient; and the plaintiffs required that it should be made one foot wider, with a rail of three feet. This he considered necessary, as horses in drawing always pulled diagonally, and where more than one horse was used, the one nearest the boat was frequently almost pulled into the water.

Mr. Pemberton (with whom was Mr. Osborne) complained that the plaintiff did not meet the proposal of the defendants, but always asked for something beyond the utmost of the offer. There was now a gangway on the outside of the coffer dam, which apparently answered all the purposes for which the plaintiffs were contending.

Mr. Colville appeared for the dock company, who refused to interfere.

Mr. Kindersley replied.

Lord Langdale observed that, assuming he had jurisdiction under the acts, it was necessary for the court to consider whether it would make any order. The defendants, it appeared, were under some mistake, as it was the duty of those who undertook such extensive speculations to apply the whole of their knowledge and experience so as not to occasion any public inconvenience. He thought, however, that a towing path was requisite, but he was without any information which could inform him what was sufficient. He certainly ought to be satisfied that the proposal made, afforded a safe path; and if that could be done, he was not disposed to make any order which could embarrass the works of the defendants.

His Lordship subsequently, after some further discussion between the parties, refused to make any order, upon the defendants undertaking to make such a towing-path as an umpire, to be appointed, should consider proper.

The plaintiffs, however, objected to a railway engineer being appointed the umpire.

RAILWAY COMPENSATIONS.

In the Sheriff's Court, on Wednesday July 18, Mr. Jones, landlord of the Wheatsheaf public-house in Anthony-street, St. George's-in-the-East, sought to recover compensation from the Blackwall Railway Company, for his premises, which are required by the company, and for the goodwill of his business. The claim was 2,500*l.*, the award of the jury 1,700*l.* In the course of the trial, it was stated, that publicans have a profit of 45s. per butt, upon porter, 35 per cent. on spirits, and nearly cent. per cent. on the minor articles of their trade.

In the Sheriff's Court, on Saturday the 11th ult., a Special Jury was called to decide to what amount of compensation the claimants Messrs. Baker were entitled, for certain premises and lands required by the Blackwall Railway Company for the prosecution of their works.

Mr. Ellis and Mr. Bromley, valuers, proved that the claim set up was not an exorbitant one. The facts of the case appeared to be briefly these:—That Messrs. Baker possessed a freehold, used as a timber yard, with several houses adjoining, in Rosemary-lane; and that Mrs. Maddock held a lease of the premises, at a rental of 50*l.*, thirteen years and a half of the term of which were unexpired. The premises were let at an improved rent of 150*l.* a year, and the valuer for the claimants calculated the fair compensation to which Mrs. Maddock was entitled, at nine years and three-quarters' purchase; which, by the 5 per cent. tables, would amount to 1,528*l.* 16s. From further calculations made in reference to the freeholder's claim, the sum demanded was 3,500*l.*

On behalf of the company, Mr. Tite the surveyor stated that the present market price was certainly not more than 3,000 guineas for both the freeholder's and leaseholder's interests in the property.

Mr. Higgins, surveyor to the Commissioners of Woods and Forests, was likewise examined, and fixed the value of the premises at 3,820*l.*

The jury, after about half an hour's consideration, awarded the claimants the sum of 4,475*l.*

RATING OF RAILWAYS.

At the quarterly sessions for the county of Chester, held at Knutsford on Tuesday, July 17th, an appeal by the Grand Junction Railway Company, against the assessment for the relief of the poor of the township of Hartford, came on for trial. It was admitted by the counsel on both sides that the distance of railway passing through the township of Hartford was one mile and 470 yards; that the amount of tonnage received by the Railway Company for the whole length of the line between Warrington and Birmingham was 1,236*l.* 0s. 6d. per mile, which, for the Hartford distance, was 1,521*l.* 13s. 6d. Mr. Cottingham, in stating the respondents' case, said that the only point in dispute between the parties, was the amount of deductions to be made on account of the expenses incurred by the Company in maintaining the railway in a working and tenantable condition. After counsel had been heard, and witnesses examined, the magistrates retired for a short time, and on again entering the court, the chairman said they were of opinion that the rate ought to be amended. They would allow 300*l.* per mile for the expenses of repairs, engineering, gate-keepers, police, and fences; 30*l.* 18s. per mile, or 2½ per cent. for the collection of the tonnage; 274*l.* 4s. per mile, being 20 per cent. as tenants' profit. The rate was therefore amended, pursuant to this decision, viz. reducing the rateable value per mile from 1,500*l.* to 607*l.*

PARLIAMENTARY PROCEEDINGS.

STEAM NAVIGATION.

***First Departure of a Steam Vessel for St. Petersburg.*—On Wednesday forenoon, the 2nd ult., the St. George's Steam Navigation Company's vessel Sirius, recently trading between London and New York, commanded by Captain Moriarty, sailed from East-lane-stairs, Bermondsey, for St. Petersburg. This is the first steam-ship which has left the Thames for the Russian capital. She had a considerable number of passengers, principally merchants, on board.**

Bristol, July 16.—A meeting of the Great Western Steam-ship Company was held this day by adjournment (at the Commercial Rooms) for the purpose of confirming or otherwise, the resolutions passed at the last meeting, which went to the creation of new shares and the extension of the capital of the company to 1,000,000*l*. The chairman explained, that in consequence of the objections of a portion of the proprietors, to the admission of new shareholders until the year 1839, the directors had determined to abide by the deed of settlement, and only at present to fill up the capital to the amount stated in the deed. The debtor and creditor accounts of the company were then read; from which it appeared that the prospects of the company were so excellent, that after setting down the expenses of the first voyage to the cost of the ship, the actual profit on the two others has been sufficient to admit of a very handsome dividend, which would be declared according to the deed of settlement on the 6th of September. It was also stated that 97 berths for her next voyage were already taken; and that the keel of another steamer, to be called the City of New York, would be laid down in the course of a few days, all the preparations being already in progress.—*Times.*

The Steam Ship Tiger.—High as were the anticipations of the capabilities of this noble vessel, she has, in practice, more than realized them. On Tuesday morning, July 31st, she dropped anchor in Hull roads on her return from Hamburg. The passage out she made in the unprecedentedly short period of thirty-five hours and a half; that home occupied forty-nine hours, three of which were spent at anchor; but the circumstances under which it was performed render it, perhaps, even more remarkable than the run out, the weather being so bad that the French steamer kept her port, and the first class steam-ships from London to Hull, even the Wilberforce, exceeded their average passage by ten hours. The Tiger is a genuine Hull-built ship, and it is confidently predicted, by those who ought to be good judges, that she will prove the fastest cargo steam-ship registered in the United Kingdom Her burden is 800 tons; her engines are of 300 horse power (having Samuel Hall's patent condensers, by which pure distilled water, instead of salt water, is supplied to the boilers); and her equipment, in every respect, does the highest credit to the port of Hull and to the owners—the St. George Steam-packet Company.—*Hull Paper.*

Incrustation of Boilers.—The following method employed by Captain Kennedy, commanding her Britannic Majesty's steamer Spitfire, to prevent the incrustations or deposits of saline matter on the inside of the boilers of steam-engines, has been communicated by him in a letter to M. Gautier, of the French consulate at Malta. Captain Kennedy recommends, after having well cleaned the boilers and tubes, to coat those parts of their interior surface most exposed to the action of the fire, with a mixture composed in the proportion of 18 pounds of melted suet and 3 pounds of powdered black lead. He states that the advantages of this application have been so fully tested by experience, that the Lords of the Admiralty have resolved (?) that all the Government steamers shall for the future be provided with a sufficient quantity of the above-mentioned ingredients.—*French paper.*

Steam-Vessel Boilers.—We understand that an *important experiment* was lately tried on the river, by the direction of C. W. Williams, Esq., with a very successful result. It is no less than a machine which effects the purpose of cleaning out the boilers of steam vessels without stopping the working of them. The apparatus is said to be the joint invention of Messrs Maudslay and Field, of London, and Mr. Scott, of Sunderland, and has hitherto been only partially (although successfully) used in the Great Western. The apparatus is exceedingly simple, as may be judged from the fact, that it was attached to the boilers of the Duchess of Kent, Dublin steamer, in ten hours.—*Liverpool Albion.*

New Fuel for Steam Navigation.—We understand that Mr. Williams, the chief director of the Dublin Steam Company, has discovered a new description of fuel applicable to the uses of steam navigation, and particularly for vessels intended for a long voyage, as it considerably diminishes the weight to be carried. It is stated that experiment has proved one ton of the new fuel to be equal in effect to four tons of the best coal. Mr. Williams has already secured the benefit of this important discovery by a patent, and the public are likely soon to be put in possession of the nature of this new kind of fuel. A discovery of this kind was alone wanted to remove the last remaining obstacle to transatlantic steam navigation—namely, the enormous dead weight of coal required for engines of great power by large vessels on long voyages. This new fuel, a specimen of which we have seen, we hear is manufactured from a description of peat or turf found in Ireland, called stone turf, from its weight and solidity, and which produces a most intense heat. This stone peat, when mixed with tar, and subjected to a very high pressure, has all the appearance of the best cannel coal.—*Liverpool Paper.*

PROGRESS OF RAILWAYS.

GREAT WESTERN RAILWAY.

Extracts from the Report of the Engineer to the Board of Directors.

Gentlemen, As the endeavour to obtain the opinions and reports of Mr. Walker, Mr. Stephenson, and Mr. Wood, prior to the next half yearly meeting, has not been successful, I am anxious to record more fully than I have previously done, and to combine them in one report, my own views and opinions upon the success of the several plans which have been adopted at my recommendation in the formation and in the working of our line; and in justice to myself and to these plans, and indeed to enable others to arrive at any just conclusion as to the result which has been attained, or as to the probable ultimate success or advantages of the system, it is necessary that I should enter very fully, I fear even tediously, into a recapitulation of the circumstances peculiar to this railway which led to the consideration and adoption of these plans; which some call innovations and wide deviations from the results of past experience, but the majority of which, I will undertake to show, are merely adaptations of those plans to our particular circumstances. * *

The circumstance of the Great Western Railway and other principal railways likely to extend beyond it, having no connexion with other lines then made, leaving us free from any prescribed dimension, *the seven feet gauge* was ultimately determined upon. Many objections were certainly urged against it, the deviation from

the established 4 feet 8 inches was then considered as the abandonment of a principle; this however was a mere assertion, unsupported even by plausible argument, and was gradually disused; but objections were still urged, that the original cost of construction of all the works connected with the formation of the line must be greatly increased.

That the carriages must be so much stronger that they would be proportionably heavier, that they would not run round the curves, and would be more liable to run off the rails, and particularly that the increased length of the axles would render them liable to be broken;—these objections were not advanced as difficulties, which existing in all railways might be somewhat increased by the increase of gauge, but as peculiar to this and fatal to the system.

With regard to the first objection, namely, the increased cost in the original construction of the line; if there be any, it is a question of calculation, which is easily estimated, and was so estimated before the increased gauge was determined upon. Here, however, preconceived opinions have been allowed weight in lieu of arguments and calculations, cause and effect are mixed up without much consideration.

It was assumed at once that an increased gauge necessarily involved increased width of way and dimensions of bridges, tunnels, &c.

Yet such is not the case within the limits we are now treating of: a 7 feet rail requires no wider bridge or tunnel than a 5 feet, the breadth is governed by a maximum width allowed for a loaded waggon, or the largest load to be carried on the railway, and the clear space to be allowed on either side beyond this.

On the Manchester and Liverpool Railway, this total breadth is only 9 feet 10 inches, and the bridges and viaducts need only have been twice this, or 19 feet 8 inches—9 feet 10 inches was found, however, rather too small; and in the London and Birmingham with the same width of way, this was increased to 11 feet by widening the interval between the two railways.

In the space of 11 feet allowed for each rail, a 7 feet gauge might be placed just as well as a 5 feet, leaving the bridges, tunnels, and viaducts exactly the same; but 11 feet was thought by some still too narrow, and when it is remembered that this barely allows a width of 10 feet for loads, whether of cotton, wool, agricultural produce, or other light goods, and which are liable also to be displaced in travelling,—13 feet, which has been fixed upon in the Great Western Railway, and which limits the maximum breadth under any circumstances to about 12 feet, will not be found excessive.

It is this, and not the increased gauge, which makes the minimum width actually required under bridges and tunnels, 26 feet instead of 22 feet.

The earthwork is slightly affected by the gauge, but only to the extent of 2 feet on the embankment, and not quite so much in the cuttings; but what in the practice, has been the result?

The bridges over the railway, on the London and Birmingham, are 30 feet, and the width of viaducts 28 feet. On the Great Western Railway, they are both 30 feet, no great additional expense is therefore incurred on these items, and certainly a very small one compared to the increased space gained, which as I have stated is from 10 to 12 feet. In the tunnels exists the greatest difference—On the London and Birmingham Railway, which I refer to as being the best and most analagous case to that of the Great Western Railway, the tunnels are 24 feet wide. On the other Great Western Railway, the constant width of 30 feet is maintained, more with a view of diminishing the objections to tunnels, and maintaining the same minimum space which hereafter may form a limit to the size and form of every thing carried on the railway, than from such a width being absolutely necessary.

Without pretending to find fault with the dimensions fixed, which have no doubt being well considered upon the works on other lines—I may state that the principle which has governed me, has been to fix the minimum width, and to make all the works the same, considering it unnecessary to have a greater width between the parapet walls of a viaduct which admits of being altered, than between the sides of a tunnel, which cannot be altered.

The embankments of the London and Birmingham Railway are 26 feet—on the Great Western, 30 feet; making an excess of about 6½ per cent. on the actual quantity of earthwork.

The difference in the quantity of land required, is under half an acre to a mile On the whole, the increased dimensions from 10 feet to 12 will not cause any average increased expense in the construction of the works, and purchase of land, of above 7 per cent—8 per cent having originally been assumed in my report in 1835, as the excess to be provided for.

With respect to the weight of the carriages, although we have wheels of 4 feet diameter, instead of three feet, which, of course, involves an increased weight, quite independent of the increase of width; and although the space allowed for each passenger is a trifle more, and the height of the body greater, yet the gross weight per passenger is somewhat less.

	Tons.	cwt.	qrs.
A Birmingham first class coach weighs - - -	3	17	2
Which with 18 passengers, at 15 to the ton - -	1	4	0
Or 631 lbs. per passenger -	5	1	2
A Great Western first class weighs - - -	4	14	0
And with 24 passengers - - - -	1	12	0
Or 588 lbs. per passenger - - -	6	6	0
And our 6-wheeled first class - - -	6	11	0
With 32 passengers - - - -	2	2	2
Or 600 lbs. per passenger - - -	8	13	2

Being an average of 594 lbs. on the two carriages.

This saving of weight does arise from the increased width, and is notwithstanding the increased strength of the framing and the increased diameter and weight of the wheels; I have not weighed our second class open carriages, but I should think the same proportion would exist.

As to the breaking of axles or running off the line, what has been the result? That from some causes or other, we have been almost perfectly free from those very objections which have been felt so seriously on some other lines. Far from breaking any engine axles, not even a single cranked axle has been strained, although the engines have been subjected to rather severe trials. One of our largest having a short time back been sent along the line at night when it was not expected, came into collision with some ballast waggons, and was thrown off the line nearly six feet; none of the axles were bent or even strained in the least, although the front of the carriage, a piece of oak of very large scantling, was shattered. After ten weeks running, one solitary instance has occurred of a carriage in a train getting off the line and dragging another with it; and this was not discovered till after running a mile and a half. As the carriage was in the middle of the train, and one end of the axle was thrown completely out of the axle guard, there must have been some extraordinary cause, possibly a plank thrown across the rail way by a blow from the carriage which preceded, and which might have produced the same effect on any railway; and at any rate, it was a strong trial to the axle, which was not broken, but merely restored to its place, and the carriage sent on to London. The same mode of reasoning which has by some been used in favour of the 4 feet 8 inch gauge, if applied here, would prove that long axles are stronger than short, and wide rails best adapted for curves. All that I think proved, however, is this—that the increased tendency of the axles to break, or of the wheels to run off the rails, is so slight, that it is more than counterbalanced by the increased steadiness from the width of the base, and the absence of those violent strains which arise from irregularity in the gauge, and the harshness of the ordinary construction of rails. In fact, not one of the objections originally urged against the practical working of the wide gauge has been found to exist, while the object sought for is attained, namely—the capability of increasing, at any future period, the diameter of the wheels, which cannot be done, however desirable it may hereafter be found, with the old width of rail. This may be said to be only prospective; but in the mean time contingent advantages are sensibly felt in the increased lateral steadiness of the carriages and engines, and the greater space which is afforded for the works of the locomotives; and here I wish particularly to call your attention to the fact, that this prospective advantage, this absence of a most inconvenient limit to the reduction of the friction which, with our gradients, forms 4-5ths, or 80 per cent. of the total resistance, was the object sought for, and that, at the time of recommending it, I expressly stated as follows:—"I am not by any means prepared at present to recommend any particular size of wheel, or even any great increase of the present dimensions. I believe they *will* be materially increased, but my great object would be in every possible way to render each part *capable* of improvement, and to remove what appears an obstacle to any great progress in such a very important point, as the diameter of the wheels, upon which the resistance which governs the cost of transport, and the speed that may be obtained, so materially depends."

These advantages were considered important by you,—they are now considered so by many others; and certainly every thing which has occurred in the practical working of the line, confirms me in my conviction, that we have secured a most valuable power to the Great Western Railway, and that it would be folly to abandon it.

The next point I shall consider is *the construction of the engines*, the modifications in which, necessary to adapt them to higher speeds than usual, have, like the increased width of gauge, been condemned as innovations.

I shall not attempt to argue with those who consider any increase of speed unnecessary. The public will always prefer that conveyance which is most perfect, and speed within reasonable limits is the material ingredient in travelling.

A rate of 35 to 40 miles an hour is not unfrequently attained at present on other railways in descending planes, or with light loads on a level, and is found practically to be attended with no inconvenience.

To maintain such a speed with regularity on a level line, with moderate loads, is, therefore, quite practicable, and unquestionably desirable. With this view the engines were constructed; but nothing new was required or recommended by me—a certain velocity of the piston is considered the most advantageous.

The engines intended for slow speeds have always had the driving wheels small in proportion to the length of stroke of the piston. The faster engines have had a different proportion—the wheels have been larger, or the strokes of the piston shorter. From the somewhat clamorous objections raised against the large wheels, and the construction of the Great Western Railway engines, and the opinions rather freely expressed of my judgment in directing this construction, it would naturally be supposed that some established principle had been departed from, and that I had recommended this departure.

The facts are, that a certain velocity of piston being found most advantageous, I fixed this velocity, so that the engines should be adapted to run 35 miles an hour, and capable of running 40. As the Manchester and Liverpool Railway engines are best calculated for 20 to 25, but capable of running easily up to 30 and 35 miles per hour; and fixing also the load which the engine was to be capable of drawing, I left the form of construction and the proportions entirely to the manufacturers, stipulating merely that they should submit detailed drawings to me for my approval. This was the substance of my circular, which, with your sanction, was sent to several of the most experienced manufacturers. Most of these manufacturers, of their own accord, and without previous communication with me, adopted the large wheels as a necessary consequence of the speed required. The recommendation coming from such quarters, there can be no necessity for defending my opinion in its favour—neither have I now the slightest doubt of its correctness. As it has been supposed that the manufacturers may have been compelled or induced by me to adopt certain modes of construction, or certain dimensions in other parts by a specification—a practice which has been adopted on some lines—and that these restrictions may have embarrassed them, I should wish to take this opportunity to state distinctly, that such is not the case. I have indeed, strongly recommended to their consideration the advantages of having very large and well formed steam passages, which generally they have adopted, and with good results; and with this single exception, if it can be considered one, they have been left unfettered by me (perhaps too much so), and uninfluenced, except indeed by the prejudices and fears of those by whom they have been surrounded, which have by no means diminished the difficulties I had to contend with.

The principal proportions of these engines being those which have been recommended by the most able experimentalists and writers, and these having been adopted by the most experienced makers, it is difficult to understand who can constitute themselves objectors, or what can be their objection.

Even if these engines had not been found effective, at least it must be admitted that the best and most liberal means had been adopted to procure them; but I am far from asking such an admission. The engines, I think, have proved to be well adapted to the particular task for which they were calculated, namely—high speeds; but circumstances prevent their being beneficially applied to this purpose at present, and they are therefore working under great disadvantages. An engine constructed

expressly for a high velocity, cannot of course be well adapted to exert great power at a low speed, neither can it be well adapted for stopping frequently and regaining its speed. But such was not the intention when these engines were made, neither will it be the case when the arrangements on the line are complete; in the mean time, our average rate of travelling is much greater than it was either on the Grand Junction or the Birmingham Railway, within the same period of the opening. I have but one serious objection to make to our present engines, and for this, strange as it may seem, I feel that we are mainly indebted to those who have been most loud in their complaints. I refer to the unnecessary weight of the engines; there is nothing in the wide gauge which involves any considerably increased weight in the engines. An engine of the same power and capacity for speed, whether for a four feet eight inch rail, or for a seven feet rail, will have identically the same boiler, the same fire-box, the same cylinder, and piston, and other working gear, the same side-frames, and the same wheels; the axles, and the cross-framing will alone differ, and upon these alone need there be any increase; but if these were doubled in weight, the difference upon the whole engine would be immaterial; but the repeated assertions, and frequently professing to come from experienced authorities, repeated until it was supposed to be proved, that the increased gauge must require increased strength and great power, was not without its indirect effect upon the manufacturer. Unnecessary dimensions have been given to many parts, and the weight thereby increased, rather tending as I believe to diminish than to add to the strength of the whole. I thought then, and I believe now, that it would have been unwise in this case to have resisted the general opinion, and taken upon myself the responsibility which belonged to the manufacturers, but I need not now hesitate to say, that a very considerable reduction may be effected, and that no such unusual precautions are necessary to meet these anticipated strains—resistance, such being in fact imaginary. It cannot surprise anybody that under such circumstances, attention was more occupied in endeavouring to meet these imaginary prejudiced objections, than in boldly taking advantage of the new circumstances, and that a piece of machinery constructed under such disadvantages, was not likely to be a fair sample of what might be done. I am happy to say, however, that the result of the trials that have been made, has entirely destroyed all credit in these alarmists with the manufacturers; and that we may hope in future to have the benefit of the free exercise of the intelligence and practical knowledge of engine manufacturers.

The mode of laying the rails is the next point which I shall consider. It may appear strange that I should again, in this case, disclaim having attempted anything perfectly new; yet regard to truth compels me to do so. I have recommended in the case of the Great Western the principle of a continuous bearing of timber under the rail, instead of isolated supports, an old system recently revived, and as such I described it in my report of January, 1836; the result of many hundred miles laid in this manner in America, and of some detached portions of railway in England, were sufficient to prove that the system was attended with many advantages, but since we first adopted it, these proofs have been multiplied; there need now be no apprehension. There are railways in full work, upon which those who are willing to be convinced, that a permanent way in continuous bearings of wood may be constructed, in which the motion will be much smoother, the noise less, and consequently—for they are effects produced by the same cause—the wear and tear of the machinery much less, such a plan is certainly best adapted for high speeds, and this is the system recommended by me and adopted on our road. There are, no doubt, different modes of construction, and that which I have adopted as an improvement upon others, may, on the contrary, be attended with disadvantages. For the system I will strenuously contend, but I should be sorry to enter with any such determined feeling, into a discussion of the merits of the particular mode of construction. I would refer to my last report, for the reasons which influenced me, and the objects I had in view in introducing the piling; that part which had been made under my own eye answered fully all my expectations. Here the piles did answer their purpose, and no inconvenience resulted from their use. The difficulties which we have since encountered; the bad state in which the line was for a considerable time, and which has only recently improved, has undoubtedly been aggravated if not caused by these piles; but not as I believe from a defect in the principle as applied in our case when the line is mostly in cutting or on the surface, but from defective execution; for notwithstanding the determination to allow sufficient time for this most important operation, yet to make up for previous delays and loss of time, it became necessary at last to force forward the work more rapidly than was at all consistent with due care in the execution; and, during the whole of this period, I was most unfortunately prevented by a serious accident from even seeing the work almost until the day of opening, whereas I ought to have personally superintended the whole. I do not mean that the work was neglected by those whose duty it was to supply my place—far from it; but, in such a case, a new work cannot be properly directed except under the eye of the master. Following exactly the plan which had succeeded on the first piece completed, several serious faults were committed; a much greater density and firmness of packing is required than was previously supposed—the mode of packing adopted and the material selected in the first instance, have proved defective elsewhere, and over a great extent of the line, particularly in the clay cuttings, and where the work was at last most hurried, it has been badly executed. But many parts have stood well from the commencement—others are fast improving; and I have the satisfaction, although a very painful one, of seeing, that if, in the first instance, a foundation of coarse gravel had been everywhere well rammed in before the timbers had been laid, and the packing formed upon this, we should from the onset have obtained as solid a road as we have now over a great part of the line. What we have been able to effect since the opening of the line, has necessarily been a slow, expensive, and laborious operation. We have been compelled to open the ground and excavate it to a depth of 18 inches under the longitudinal timbers, and this without interrupting the traffic. To remove the whole of the material thus obtained from off the line, and to replace it by coarse ballast; and not having the means of sufficiently consolidating this ballast by ramming while the timber is in its place, the packing has to be repeated once or twice after it has been compressed by the passing of the trains. This new packing, however, does stand; and, in a few weeks, I expect that the line will be in a very different state from that in which it has been, or indeed now is, from what I have described as the result which can now be, and might have been, obtained. From the commencement, it will be inferred that I am disposed still to defend the system of piling. I certainly could not abandon it from conviction of its inefficiency, for I see proofs of the contrary; and I feel that, under similar circumstances, I could now prevent the mischief that has occurred. Upon that portion of the line where the permanent way must next be formed, piling could not be resorted to, the ground being a solid hard chalk for many miles. I had intended, however, recommending the same principle, but in a different form, holding down the longitudinals by small iron rods driven into the chalk; but the same objection could not exist, because the chalk cannot yield under the timbers like clay or even gravel. But I should wish most anxiously to avoid anything like obstinate adherence to a plan, if the object I believe essential can be obtained by any other means; particularly when that plan, being my own, I may be somewhat prejudiced in its favour. I find that the system of piling involves considerable expenses in the first construction, and requires, perhaps, too great a perfection in the whole work; and that if the whole or a part of this cost were expended in increased scantling of timber and weight of metal, that a very solid continuous rail would be formed; for this as a principle, as for the width of gauge, I am prepared to contend; and to stand or fall by it, believing it to be a most essential improvement where high speeds are to be obtained. I strongly urge upon you not to hesitate upon these two main points, which, combined with what may be termed the natural advantages of the line, will eventually secure to you a superiority which, under other circumstances, cannot be attained.

As regards *the expense of forming the permanent way* on this principle, I am quite prepared to maintain what I have on a former occasion advanced, that even on the system which we have adopted between London and Maidenhead, the total cost does not materially exceed that of a well constructed line with stone blocks. I did not make in the outset an exact estimate of the total cost of either mode. I was unable to obtain the cost which has actually been incurred on other lines; but a comparative estimate was made, and the result of that comparison led me to state that the one might exceed the other by 500*l.* a mile. The actual cost of our permanent way appears by the detailed account, which has been made out, to have been above 9000*l.*, including expenses of under-draining and forming the surface, which cannot be included in the cost, given in other cases, because that drainage, although, I believe, generally forming part of the plan, is not yet constructed; this sum includes the sidings at the stations, switches, points, and other contingencies, and also the expenses incurred during the first month of working the line, and which, as I have before stated, consisted in removing and replacing work which had been improperly executed. These items will make a considerable reduction; and besides these, larger reductions may be effected in parts of the work which were new, and from the circumstances naturally attending a first attempt were not so economically conducted as they might be, or indeed, as they were towards the close of the works, when the different parts were let by contract. Taking the prices at which the work was latterly actually executed, 8,000*l.* per mile would be a liberal allowance for our future proceedings even adopting the same system; and with a modified system such as that suggested, of simple longitudinal bearers of large scantling and rail of 54lbs. per yard, at the present high price of iron, the cost calculated upon our actual past expenditure would not exceed 7400*l.* per mile. This I am aware is a larger sum than that which has usually been assumed as the cost of the permanent way. I cannot prove that others have cost more, or even so much as this, as I have nothing but the published accounts to refer to; but this I can state and prove if necessary, that rails and blocks such as are now being adopted on the Manchester and Liverpool Railway, would upon our line cost at least as much.

The prime cost of rails and chairs delivered on the line, would alone amount to half the money; and nothing is perhaps more certain, than that the experience of other lines within the last two or three years, has proved that this part of the construction of a railway is unavoidably much more expensive than was ever calculated for, at the time our estimates were made.

I am, Gentlemen,

Your obedient servant,

I. K. BRUNEL.

THE BIRMINGHAM BRISTOL AND THAMES JUNCTION RAILWAY.

The Directors are happy to report, that the differences which existed at the last general half yearly meeting as to whether the Railway should pass over or under the Paddington Canal, have been removed.

In order finally to settle this question, which impeded the execution of the works at a point where completion was necessary before further works could properly proceed, the Board determined to submit the question with every information they possessed bearing on the subject, to the decision of Mr. Vignoles, an engineer wholly unconnected with either of the great lines of Railway with which the Thames Junction Railway is intended to communicate, and whose eminence in his profession and skill were universally admitted.

Mr. Vignoles having been accordingly consulted, reported to the Board his opinion, that the line of railway laid down to pass under the Paddington Canal was the preferable method to be adopted by this Company, having reference to the circumstance that the Thames Junction Railway was projected to communicate with the London and Birmingham and Great Western Railways, and also with the Paddington Canal.

In consequence of this opinion, which was also in accordance with that of Mr. Cubitt, the eminent engineer, who had originally been consulted, the Directors immediately instructed Mr. Cubitt, the contractor, to proceed with the important work of the proposed gallery under the Paddington Canal, and the Directors are happy to report that it is in so advanced a state that by the 11th of next month it will be completed. The Paddington Canal will then be diverted; for which purpose the necessary excavation has, for some time past, been finished, and the engineer will then be enabled to obtain soil from his excavations between the Gallery and the Birmingham Railway, to proceed with the embankment across Eynham Farm towards the Uxbridge road.

That embankment has now reached Eynham Farm, and will be completed from the soil to the north of the Paddington Canal. The work of forming the line from the London and Birmingham Railway to a field adjoining the Uxbridge road, has been let to responsible contractors upon terms satisfactory to the Board.

The Directors are also happy to state that the differences which existed between them and the Great Western Railway Company, have been removed; and that an improved mode of intercommunication of the two railways, recommended by Mr. Vignoles and Mr. Hosking, has been arranged between the engineers of the two companies.—*Extracted from Directors' Report.*

The London and Southampton Railway is expected to be opened as far as Hook in the course of this month.

We understand an application is about to be made to Parliament for the construction of a branch railway from Newbury, to form a junction with that of the Great Western.

London and Birmingham Railway.—On Monday the 20th ult., a large party of Directors and Proprietors breakfasted at the Birmingham station; and at half-past six, they left, with one of Mr. Bury's engines, to make the first excursion along the entire line to London, where they arrived at the Euston station at one o'clock, without any kind of accident, or circumstance to interfere with the pleasure of the journey. The time occupied in travelling was exactly five hours, the other hour and a half being devoted to the examination of the stupendous and interesting works on the new part of the line, much of which is yet incomplete. The distance to Coventry, 18¼ miles, has performed in 36 minutes; from Coventry to Rugby, 11 miles, in 22 minutes; from Rugby to Denbigh Hall, 35 miles, in 2 hours and 10 minutes; and from Denbigh Hall to London, 48 miles, in 1 hour and 54 minutes: in all 5 hours and 2 minutes. The Kilsby Tunnel has been constructed in defiance of immense physical difficulties, and is a work which has excited the greatest interest and admiration. When the party arrived at the central shaft, which has a diameter of sixty feet, they were saluted with hearty cheers from a number of workmen who had stationed themselves at its summit far above the subterranean travellers, who responded to the welcome. The rocky excavation at Blisworth, extending through a considerable extent of country, astonished the visitors perhaps as much as any other part of the line; and must be seen, to enable any person to form an adequate idea of its character. The Wolverton viaduct, excited great admiration; and many of the proprietors walked down the embankment to enjoy a view of the beautiful structure from the meadows below. At the great Wolverton station, or central depôt for the engines, the workshops and arrangements were inspected, and refreshments were liberally provided. The remainder of the journey, although entitled to notice, presented fewer features of novelty. The jaunt gave much satisfaction.—*Midland Counties Herald.*

Northern and Eastern Railway.—The whole of the land between Waltham Cross and Broxbourne is now in possession of the Company, with the exception of a small piece belonging to the Ordnance Office, and the works are in rapid progress. At Broxbourne, the bridge over the mill-dam has been commenced,—the plans for the station-house have been approved,—and the notices as far as Roydon are now being served. South of Waltham Cross, the lands belonging to Mr. Dyson and to Bethlehem Hospital, are also in the possession of the Company; and, as soon as the Edmonton Jury cases are at an end, the communication between Waltham Cross and the two miles of the line which are already finished at Tottenham, will be complete. We still think that the first eleven miles may be opened on the 1st of June, 1839, and that the line between Broxbourne and Harlow will also be ready for public use by the 1st of June in the following year.—*Herts Reformer.*

Gloucester and Birmingham Railway.—The works are proceeding with great vigour along the entire line, those in our immediate vicinity advancing as rapidly as on any other portion of the line. The new road from Westhall-green to the depôt near the Gloucester-road is completely formed, and the excavations for the depôt itself have been carried on to a very great extent. The preparations for the bridge across the Gloucester road have also been commenced in earnest.—*Cheltenham Looker-on.*

Midland Counties Railway.—The neighbourhood of Spondon, near Derby, has presented a busy scene for the last week. A diversion of the canal had to be made by the Railway Company, which could not be effected without stopping the navigation, for which there was a penalty of 2*l per hour.* The contractor (Mr. Mackenzie) taking advantage of a stoppage of the canal, mustered his forces from the other parts of the contract; and has succeeded in executing the diversion while the repairs of the canal were going on, to the astonishment of the natives. Between 200 and 300 men were employed in a very small space, and when all busily at work, presented a very animated spectacle. To induce the men to persevere and work an extra number of hours, Mr. Mackenzie supplied them daily with a substantial dinner of beef and ale (in addition to their wages), which was served out and eaten on the works.—*Railway Times.*

Midland Counties Railway.—The works on this line are in a great state of forwardness between Nottingham and Derby. Several miles of road are ready for laying the permanent way: *and one-half of the whole length will be laid by the end of the present year,* unless the weather should prove unfavourable. The public may expect the *above named portion of the line to be opened on the 1st of May, 1839.* The line between Nottingham and Derby, it is anticipated, will be better than any yet made, as the rails are stronger in section than any now in use; the blocks are of a very superior quality, and the materials for ballast of the best description for the purpose. A beautiful cast iron bridge is to be built over the river Trent, at Red Hill; it will consist of three arches, each of 100 feet span. The contractor is now constructing the coffer dam for the pier; he has also commenced the tunnel through the ridge near Red Hill. From the Trent to Leicester, the contractors are proceeding with the greatest possible despatch. Nearly 4,000 men are employed, viz.:—800 on the Nottingham and Derby line, about 1,200 between the Trent and Leicester, and nearly 2,000 between Leicester and Rugby. The line across the meadows approaching the Nottingham station, is proceeding with railway celerity, and the contractors feel confident that this part of the line will be finished long before the stipulated time.—*Derbyshire Courier.*

North Midland Railway.—It is calculated that the double line of permanent rails, for the North Midland Railway, will weigh about 180 tons per mile.—*Sheffield Mercury.*

Sheffield and Manchester Railway.—The survey of this railway is, we are glad to learn, proceeding rapidly. From the entrance into Manchester to Durnford Bridge, the exact line has been determined; and for nearly the whole of the distance, the breadth of land required has been nicked out upon the ground, and negotiations opened for its purchase. We understand that Mr. Vignoles will proceed shortly with the staking out on the Yorkshire side.—*Sheffield Mercury.*

New Junction Railway.—Amongst the railways now in course of execution in the manufacturing districts, the Manchester and Leeds is perhaps the most important. From the directors of this railway, the Liverpool and Manchester board have lately received a proposition to consider the desirableness of a connecting railway, of something less than two miles in length, to unite two main lines in the immediate vicinity of Manchester; thus forming a continuous line of railway from Liverpool to Leeds, or by means of the Selby Railway, to Hull. The subject of this proposition is one of great importance, and accordingly will receive the best consideration of the directors.—*Leeds Intelligencer.*

Branch Railway to Stalybridge.—We understand it is the intention of the gentlemen of Ashton and Stalybridge to apply for an act of parliament to connect those townships with a branch railway from the Sheffield line. The land is already staked. When executed it will be a great convenience to the inhabitants.

North Union Railway.—The most strenuous and active efforts are in progress for the completion of this line. The contractors are making every possible exertion to effect an opening into the town as early as possible in the next month. The works of the Ribble Bridge have of late proceeded very satisfactorily, and with extraordinary expedition.

Preston and Wyre Railway.—Owing to an unparalleled season of cold and wet weather during the present summer, this work has not progressed as much as was anticipated; yet much has been done on the line in the cuttings, &c. by the contractor, who has taken the advantage of keeping the men employed both day and night when the weather permitted, the sets working 8 hours at a time. A portion of the line between Poulton and Burn Naze has been permanently laid; and in the course of a fortnight it is expected that there will be a locomotive engine at work, which will be the means of forwarding the same with greater rapidity. The wall or embankment at Wyre, between Burn Naze and Fleetwood, is going steadily on under the able superintendence of Mr. D. Cowling, C.E. About 16 barges are employed daily in bringing gravel from Knot End to Burn Naze, for the purpose of ballasting the permanent road.—*Preston Pilot.*

Great North of England Railway.—On Wednesday, July 18, the first stone of the bridge over the river Ouse at Poppleton, near York, was laid by C. H. Elsley, Esq., Recorder of York, one of the directors of the Company. We are informed, that it is contracted to be completed in August, 1839, and we understand that the whole line from York to Darlington will be opened before the commencement of the year 1840. The bridge will be built with stone from the quarries at Knaresborough, according to the design furnished by Messrs. J. and B. Green, of Newcastle upon-Tyne: it will consist of three semi-elliptical arches of 66 feet span each, rising 19 feet above the springing. The total length will be nearly 300 feet, by 29 feet wide, and it will be about 30 feet high above the summer water level. The corner stone laid on this occasion weighed about four tons. The works near Northallerton, which were in a state of great forwardness and partly finished on the South side of the Castle Hill, were unfortunately stopped on Wednesday evening, by the sudden fall of a massive bridge, nearly finished, over the Willow Beck. By this accident three men have been severely injured; it happened however providentially, that most of the workmen had left a few minutes previous to its fall, or the consequences might have been fatal to several of them.—*Tyne Mercury.*

Edinburgh and Glasgow Railway.—The Directors of this spirited undertaking are about to commence immediate operations, and the first section of the work, of nearly five miles in length, in the parish of Ratho and neighbourhood, will be begun whenever the contracts are concluded—probably in October next. We consider this undertaking as a great national improvement, which must lead to the most benefical effects to the inhabitants of Edinburgh, Glasgow, and the public at large.—*Edinburgh Observer.*

Glasgow and Ayr Railway.—The contractors for executing the section of the railway lying nearest Ayr are proceeding with great vigour. A number of men have for some time been employed in cutting a pass through an elevation about half way between Prestonwick toll and the sea. The material excavated being pure sand, is easily handled, and admits of great celerity of motion on the part of the labourers.

Government have notified that they will not advance one shilling to the projected Irish Railway speculations.—*Limerick Chronicle.*

Powerful Railway Engine.—On Monday the 20th ult., the largest locomotive engine ever made in Leeds was tried on the Leeds and Selby Railway, by the makers, Fenton, Murray, and Jackson, previous to its being sent to the Paris and Versailles Railway, in France. With only one carriage and the tender, this engine travelled at the rate of 60 miles an hour; and at the rate of 20 miles with 110 tons, both on the level part of the line. In consequence of some improvement in the fire-box, this engine seems to do its work with ease; as, during the trials, it produced more steam than was required, and with the fire-door kept open. By good judges, we believe this locomotive engine is considered to be of the first-rate workmanship and finish, and to do great credit to the makers.—*Leeds Mercury.*

An Ingenious American Proposal for illuminating Railways.—A writer in the *National Intelligencer* (an American paper) states, that Mr. Herron, a distinguished civil engineer on the Gasten and Raleigh Railway, proposes to illuminate railways during night travel by a light shed in front of the locomotive, so strong and brilliant as to illuminate objects to a considerable distance ahead. The description of the mode in which he proposes to accomplish his purpose, is as follows:—"The chimney of the locomotive now in general use is placed foremost on the road. This end of the boiler is covered by a large sheet iron box, rounded at top, and surmounted by the chimney. The flame from the furnace passes through the boiler into this box, by means of from sixty to one hundred and forty tubes, each nearly two inches in diameter, so that the end of the boiler, which also forms the inner end of the box, presents an appearance much resembling a honeycomb: and from each cell, when the engine is in motion, a bright jet of flame issues and curves upwards towards the chimney, so that the whole interior of the box is filled with one intense sheet of flame. The waste steam from the cylinders is conducted by a pipe through the box to the inferior orifice of the chimney, up which it is discharged with great force, in the form of a jet, which drives the air in the chimney before it, and draws that contained in the box after it, thus forming a vacuum, which is immediately filled by the flame from the furnace. In the external end of the box, immediately under the chimney, is a sheet iron door, of rather an elliptic form, and of sufficient size to admit a man with ease to make any necessary repairs on the tubes, &c. Suppose we remove this sheet-iron door, and cover the orifice closely with a large semi-circular lantern, glazed with small panes of glass or talc; it would seem to be a reasonable inference that a very brilliant light must be emitted, exceeding that of any lighthouse. It would be proper to place a fine wire netting over the orifice first, to keep sparks out of the lantern: and if glass is used, it should be slightly oiled, to keep it from cracking by heat. Perhaps a very fine wire gauze, similar to that employed by Sir Humphrey Davy in his celebrated safety lamp, might alone, without the lantern, prove more efficient, as it would admit a small quantity of atmospheric air, thus rendering the combustion more perfect, and increasing the brilliancy of the flame. The whole end of the box might be thus formed, and it would be less liable to injury or accident than the lantern. It will be perceived that the experiment can be made on most of the locomotives now used, without any alteration whatever of their parts, and at a trifling expense: and this expense will be quickly repaid by dispensing with the oil consumed in the lamps so uselessly at present."

NEW CHURCHES.

New Church at Morningside.—On Sunday, July 29th, the new church recently erected in the village of Morningside, was opened for the first time, for public worship, by the Rev. Dr. Chalmers. The site and the building are both very much admired. The plans were furnished by our townsman, Mr. Henderson, architect, London-street; whose professional talents and correct taste have been eminently displayed in the numerous churches recently erected under his superintendence, and which have given universal satisfaction.—*Edinburgh Advertiser.*

The New Synagogue in Great St. Helen's.—This edifice has just been completed, under the superintendence of Mr. Davies, and is unquestionably one of the most elegant and finished buildings in the metropolis. The ceiling is reckoned unrivalled in its kind: it is adorned with flowers, which are at the same time large and most finely wrought, and which serve to conceal apertures, by the means of which the whole building is ventilated. The pillars are of the Corinthian order, those that are along the gallery being white, and those by the altar in imitation of yellow marble. The steps to this altar are of real marble, and most massive in appearance. The small rails in front of the ladies' gallery, and the mouldings about the altar, are richly gilded, yet with such taste and delicacy that magnificence never degenerates into gaudiness. The arabesque paintings of the windows are splendid, and still the some good taste has kept them within the bounds of delicacy and neatness. The woodwork, namely, the seats and reading-desk, is of a good substantial character, and of a wainscot colour. Those parts of the building which are not immediately connected with divine service, such as the committee-room, the readers' apartment, &c., are most complete in their way; and though, of course, less striking, reflect the greatest credit on the designer of the whole.—*Times.*

PUBLIC BUILDINGS AND IMPROVEMENTS.

Birmingham Railway Terminus.—Two extensive buildings are in progress at the Euston Square terminus, immediately opposite to the grand entrance; the one to be appropriated for an hotel, and the other for dormitories, with a spacious coffee room on the ground floor. Philip Hardwicke Esq is the architect, and Messrs. Grissell and Peto are the contractors.

London University College.—On the 1st ult. a number of workmen commenced rebuilding that portion of the premises which was destroyed accidentally by fire two years ago. The work is expected to be completed in three months.

Manchester.—Three statues are in contemplation in th's town; a colossal one of the Duke of Bridgewater, which Lord F. Egerton has generously offered to the town at his own expense; one of Dr Dalton, whose scientific attainments do honour to his native place, and which is to be done by public subscription; and the third, to the late James Watt.

Green Market, Newcastle-on-Tyne.—This capacious place forms part of a covered market, the most extensive in Europe, the parallelogram of buildings occupying a space of 13,906 yards. The vegetable market, or Green-market, as it is called, is 338 feet long and 57 feet wide. Its lofty roof of open timber framing, which is gracefully thrown into a frame combining strength with elegance, is supported by metal pillars; and when viewed in perspective from either end, presents the grandeur of a cathedral, rather than the mere carpentry of a market-place. Two handsome stone fountains are placed in the midst of the market, in a line with two of the cross; and at each end are two recesses, in one of which is a clock, whilst the other contains the arms of Newcastle.—*Times.*

Newcastle-on-Tyne.—The colossal statue of Earl Grey, by E. H. Bailey, R.A., intended to be placed on the pillar now nearly finished at the top of Grey street, arrived here on Monday the 20th ult, and was removed by two waggons from the Quay to the site of the monument. It is expected to be raised in a few days. The height of the pillar from the ground is 121 feet, and the statue, including the plinth, is 14 feet; when placed in its proper position, the mean height will be 135 feet.—*Tyne Mercury.*

Monument to Sir Walter Scott in Selkirkshire.—It gives us much pleasure to learn, that the gentry and inhabitants generally of the county of Selkirk—that county with which Sir Walter was so intimately connected through the greater portion of his life—have determined on erecting a testimonial of their respect and admiration for his memory; and that the town council of Selkirk have, in the most handsome manner, unanimously granted a site at the Market Cross. A statue and pedestal, to be enclosed with a railing, has been agreed upon by the managing committee; and Mr. Alexander Ritchie, of Musselburgh, one of our most distinguished sculptors, has been engaged to execute the work, according to one of two designs which have been agreed on; the one to cost three hundred, and the other five hundred pounds. As the latter comprehends a pedestal highly ornamented with figures in *alto relievo*, we hope that the subscriptions, which are rapidly filling in, will be found adequate for its adoption. The Duke of Buccleuch, with his usual liberality and patriotic spirit, has come forward to head the subscription, with a sum of fifty guineas.—*Edinburgh Observer.*

FOREIGN INTELLIGENCE.

French Steam Carriage.—The *Nouvelliste* states that a steam carriage is to start from the Carrière de l'Etoile, on Sunday next, to proceed to Brussels, the engineer expecting to do the distance, 60 leagues, in 12 hours.—*Times, Aug.* 18.

The site of the Archiepiscopal Palace on the South and East of Notre-Dame is to be converted into a public promenade, and the approaches to the cathedral improved. A contract for the masonry and iron work has been granted by the municipality of Paris; and the total expense is estimated at more than 100,000 francs.

Brussels, August 2.—This morning a trial was made on the iron railway, of a perpetual motion, which is intended to supersede steam in drawing the trains. This unknown and mysterious power, which has excited the solicitude of our greatest capitalists, was such that it forced the waggons off the rails after they had run about three yards. The secret did not transpire.

Railways in Belgium.—The railway from Brussels to Ostend is advancing with admirable rapidity, and that from Ghent to Lille proceeds with equal speed. We are assured that the latter will be positively completed in November, 1839.—*Morning Herald.*

The Bruges and Ghent Railway was opened at the former city last month, with great ceremony, in the presence of the King and Queen of the Belgians, the civil and military authorities, and the commercial guilds of the city.

It seems that the destruction of the church at Hoorn, arose from the carelessness of the plumbers who were at work in the gutters. This church was one of the largest and handsomest in the kingdom; it was dedicated to St. John the Baptist and St. Cyprian. It was in the form of a cross; 300 feet long, 120 feet broad, and 67 feet high. The steeple was 170 feet high, had remarkable heavy bells, and a fine carillon; the organ, which was very fine, was built in the years 1744-1777. The expenses of rebuilding the church will be enormous, but it will be ardently desired by all patriotic citizens; the damage is estimated at about 400,000 florins; nothing was insured.—*Dutch Paper.*

New Machine for Spinning Flax.—We learn from Hamburgh that a gentleman of that town, named Grimm, has invented a machine for spinning flax, which will produce in one day as much thread as 300 spinners could produce in the same time with spinning wheels. An Englishman is said to have offered him 60,000 marcs (about 4,000*l.*) for the machine, which he has refused, wishing to speculate himself upon his invention.

Railway from Venice to Milan.—By letters from Italy, it appears that the directors of this great undertaking, for which a capital of 50 millions Austrian lires (about 1,700,000*l.* sterling) in 50,000 shares, is subscribed, are in daily expectation of receiving from the Emperor of Austria its still required conclusive privileges. Already the plans of the line and the calculations of the levels and inclines are completed. This railway will pass through the most densely populated and the most interesting parts of the Lombardo-Venetian kingdom, connecting the splendid capitals, Milan and Venice, by the ancient towns of Brescia, Verona, Vicenza, and Padua, besides numerous smaller intermediate places. The length of the whole line from Venice to Milan will be 271,361 metres, or about 146½ Italian or English miles. It will cross many rivers, many canals and high roads. It will cross the post roads 11 times—four times on the same level, six times almost on the same level, and in one instance only, at an elevation of three metres. None of the inclinations will exceed 3 in 1,000, and in the entire length of the road, being, as stated, 271,361 metres, this very inconsiderable maximum in elevation extends over 24,014 metres only, divided into five tracts, none of which exceeds 6,000 metres (or little more than three English miles) in length—all at some distance from each other, and in many instances favoured by a counter inclination, so that the locomotive engines may with perfect ease run the whole length of the line, without the assistance of additional power. Although this railway will traverse a country highly cultivated, the amount required for indemnities, for demolitions as well as decrease in value of buildings, &c., will scarcely reach 500,000 Austrian lires (about 17,000*l.*) The calculations of the lateral line from Bergamo to Triviglio are also rapidly approaching towards completion. The above results are deemed highly favourable, and have much increased the hope for the success of this splendid undertaking, which fairly promises an important increase to the prosperity of the port of Venice and all Lombardy.—*From a Correspondent of Gore's Liverpool Advertiser.*

Australia.—The thriving town of Sydney is now about to be supplied with water, on the catchwater system. Large reservoirs have been formed in distant marshes; and the water will be led by pipes, furnished by her Majesty's Board of Ordnance to *Hyde Park*, in that colony. Considerable difficulty has occurred in the levels; the Australian engineers being rough hands with the levelling staff. At present, the town is supplied by water-carts, and with a very bad article. The best house and shop in Sydney lets for about 1,500*l.* per annum; and so thriving is trade, that middling situations find ready customers at 150*l.* and 200*l.* per annum. When we consider that the large manufacturing towns of our own country;—Leeds, Bradford, Wakefield, &c., are still so indequately supplied with water, we cannot but admire the liberality and good sense of the New World, in so early providing themselves with the means of health and cleanliness.

MISCELLANEA.

Pontoon Bridge Building.—A trial of Colonel Blanshar's pontoons, or buoys, took place one day last week at Cuxton, nearly three miles above Rochester Bridge. The pontoon equipment having been landed on the Marsh, a bridge consisting of 20, pontoons at open order, extending 260 feet, was laid across the Medway in 20 minutes. Eight companies of Royal Marines then marched over, six deep, and returned at "double quick," four deep. A detachment of cavalry, consisting of one officer and 12 privates, passed over in files and returned in single ranks. Part of the bridge was then dismantled, and two rafts were formed of three pontoons each, and prepared for field pieces to fire from them. The remainder of the bridge was then broken into rafts, on board which about 130 Marines were conveyed down the river, and co-operated with an artillery and musketry fire in an attack made by a party of Marines on shore upon another party posted at the Cuxton limekiln; but the tide having fallen considerably, the troops and guns did not land from the rafts but proceeded to the gun wharf.—*Morning Post, August* 15.

Balloons.—In a long and elaborate memoir concerning the refraction of the atmosphere, read before the Academy of Sciences by M. Biot, that gentleman proposes, that each great observatory in Europe should be provided with fixed balloons, rising to different elevations, attaining the greatest possible height, and carrying self-registering instruments, of the requisite kinds, for the measurement of the physical elements which characterize the state of the air.

Sir John Herschel's Observations.—The Duke of Northumberland has munificently offered to defray the expense of reducing Sir John Herschell's invaluable astronomical observations in the Southern hemisphere. This is, indeed, the right use of wealth; an act worthy of the nobleman who holds the high position of President of the British Scientific Association.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 26TH JULY AND 31ST AUGUST, 1838.

Wilton Wood, of Liverpool, in the County of Lancaster, Merchant, for "An improved method of mak ng Bands and Tackling, to be used in drawing, turning, or carrying Machinery."—26th July; 6 months.

George Holworthy Palmer, of New Cross, in the County of Surrey, Civil Engineer, and George Bertie Paterson, of Hoxton, in the County of Middlesex,

Engineer, for "Certain Improvements in the mode of preparing, constructing, and adapting certain parts of Gas Meters."—28th July; 6 months.

ANDREW PAUL, of Doughty Street, St. Pancras, in the County of Middlesex, Surgeon, A.B. and M.B., for "An improved Hydraulic Pump, Douche, or Jet d'Eau, applicable to all the purposes of Lavement in Medical Operations."—30th July; 6 months.

ROBERT HENDLY, of Belgrave Street, St. Pancras, in the County of Middlesex, Doctor of Medicine, for "A Metallic Concrete capable of being, by means of fire, cast into a variety of forms, and applied to a variety of purposes for which Iron, Lead, Zinc, Copper, and other Substances have been heretofore used."—30th July; 6 months.

SAMUEL HALL, of Basford, in the County of Nottingham, Civil Engineer, for "Improvements in Steam Engines, Heating or Evaporating Fluids or Gases, and Generating Steam or Vapour."—30th July; 6 months.

JOSEPH RAYNER, and JOSEPH WHITEHEAD RAYNER, of Birmingham, in the County of Warwick, Civil Engineers, and HENRY SAMUEL RAYNER, of Ripley, in the County of Derby, Civil Engineer, for their "Improvements in Machinery for Roving, Spinning, and Twisting Cotton, Flax, Silk, Wool, and other Fibrous Materials."—31st July; 6 months.

EDWARD HEARD, of Bateman's Buildings, Soho Square, in the County of Middlesex, Manufacturing Chemist, for "Certain Improvements in Oxydizing Lead, and converting the same into Pigments, or White and Red Lead, and Manufacturing part of the products arising from these processes into Soda."—1st August; 6 months.

GEORGE, MARQUESS OF TWEEDDALE, for an "Improved Method of Making Tiles for Drainings, Soles, House Tiles, Flat Roofing Tiles, and Bricks."—1st August; 6 months. To extend to the Colonies only.

EDWIN WHELL, of Walsall, in the County of Stafford, Tallow Chandler, for "An Improvement or Improvements in the Manufacture of Candles."—1st August; 6 months.

JOHN DENNETT, of New Village, in the Isle of Wight, in the County of Hants, Engineer and Surveyor, for "Improvements in War Rockets, and the methods and apparatus for applying the powers of Rockets, for the purpose of obtaining communication with Vessels which are stranded, or in other situations of danger; also an improved Instrument and Method for accurately Pointing Mortars for throwing Shells, which may likewise be used for Firing Shot from Mortars, for the purpose of obtaining communication with Ships."—2nd August; 6 months.

SAMUEL SANDERSON HALL, of the Circus, Minories, in the City of London, for "Improvements in Preserving certain Vegetable Substances from decay. Communicated by a Foreigner residing Abroad."—3rd August; 6 months.

THOMAS LUND, of Cornhill, in the City of London, Cutler, for "Improvements in extracting Corks from Wine and other Bottles with steadiness, facility, and safety."—3rd August; 6 months.

CHARLES BOURJOT, of Coleman Street, in the City of London, Merchant, for "Improvements in the Manufacture of Iron."—3rd August; 6 months.

ROBERT WILLIAM SIEVER, of Henrietta Street, Cavendish Square, in the County of Middlesex, Gentleman, for "Certain Improvements in Looms for Weaving, and in the Mode or Method of producing Figured Goods or Fabrics."—6th August; 6 months.

PIERRE ARMAND LE COMTE DE FONTAINEMOREAU, of Charles Street, City Road, in the County of Middlesex, for "Certain Improvements in Wool Combing. Communicated by a Foreigner residing Abroad."—6th August; 6 months.

RICHARD RODDA, of the Parish of St. Austle, in the County of Cornwall, Assay Master, for "Certain Improvements in Furnaces, Fire-places, and Stoves for the Consumption of Smoke and the saving of Fuel, and in the mode of applying them to the Generation of Steam, the Smelting of Metals, and other Works."—7th August; 6 months.

EUGENE DE BEURRET (commonly called VISCOUNT DE BEURRET), of 28, Moorgate Street, in the City of London, for "Certain Improvements in the Construction of Railroads and Tramroads to facilitate the ascent and descent of Hills and inclined Planes Communicated by a Foreigner residing Abroad."—10th August; 2 months.

MATTHEW HEATH, of Furnival's Inn, in the City of London, Gentleman, for "Improvements in preparing Tobacco, and in making Snuff. Communicated by a Foreigner residing Abroad."—10th August; 6 months.

THOMAS CORBETT, of Plymouth, in the County of Devon, Gardener, for "Certain Improvements in Heating Hot-houses and other Buildings."—10th August; 6 months.

DAVID CHEETHAM, Junior, of Staley Bridge, in the County of Chester, Spinner, for "Certain Improvements in the means of Consuming Smoke, and thereby economizing Fuel and Heat in Steam Engines, or other Furnaces or Fire places."—14th August; 6 months.

CHARLES WYE WILLIAMS, of Liverpool, in the County of Lancaster, Gentleman, for "Certain Improvements in the Process or the Mode of Purifying or Preparing Turpentine, Rosin, Pitch, Tar, and other bituminous matters, whereby he increases their Power of giving out Light and Heat either when Distilled or Burnt as Fuel."—14th August; 6 months.

WILLIAM HENRY PORTER, of Russia Row, Milk Street, Cheapside, in the City of London, Warehouseman, for "Improvements in Anchors."—15th August; 6 months.

RAMSAY RICHARD REINAGLE, of No. 13, George Street, London University, Royal Academician, and the Chevalier GEORGE ROBERT D'HARCOURT, of No. 6, King William Street, in the City of London, Civil Engineer, for "Certain Improvements in the means of Propelling Canal Boats, Steamers, and other Vessels."—15th August; 6 months.

GEORGE ROBERT D'HARCOURT, of King William Street, in the City of London, Civil Engineer, for "Improvements in the Manufacture of Paper. Communicated by a Foreigner residing Abroad."—15th August; 6 months.

CHARLES FOX, of No. 28, Gloucester Place, Camden Town, in the County of Middlesex, Engineer, for "An improved arrangement of Rails for the purpose of causing a Railroad Engine, Carriage, or Train, to pass from one Line of Rails to another."—15th August; 2 months.

MATTHEW WARTON JOHNSON, of Buckingham Place, in the County of Middlesex, Sculptor and Stone Mason, for "Improvements in the Construction of Coffins."—15th August; 6 months.

WILLIAM WAINWRIGHT POTTS, of Burslem, in the county of Stafford, China and Earthenware Manufacturer, for "Certain Improvements in Machines applicable to the Printing or Producing Patterns in one or more Colours, or Metallic Preparations to be transferred to Earthenware, Porcelain, China, Glass, Metal, Wood, Cloth, Paper, Papier Mache, Bone, Slate, Marble, and other suitable substances."—21st August; 6 months.

NICHOLAS TROUGHTON, of Broad Street, in the City of London, Gentleman, for "Improvements in the Process of obtaining Copper from Copper Ores."—21st August; 6 months.

SAMUEL STOCKER, of the City of Bristol, Machinist, for "Improvements in Chimneys for Dwelling-houses, and in Apparatus for Scraping, Sweeping, or Cleaning Chimneys, and in the Manufacture of such Apparatus and of the Materials of which such Chimneys are formed."—21st August; 6 months.

RICHARD BRADLEY, WILLIAM BARROWS, and JOSEPH HALL, of Bloomfield Iron Works, in the Parish of Tipton, in the County of Stafford, Iron Masters and Copartners, for "An Improved Method or Means of Making Iron."—21st August; 6 Months.

JEAN LEANDRE CLEMENT, of Rochfort, in the Kingdom of France, but now of Janney's Hotel, Leicester Square, in the County of Middlesex, Gentleman, for "Improvements for ascertaining and indicating the Rate of Vessels passing through the Water."—21st August; 6 months.

PIERRE ARMANDE LE COMTE DE FONTINEMOREAU, of Charles Street, City Road, in the County of Middlesex, Gentleman, for "Certain new and improved Metallic Alloys, to be used in various cases as substitutes for Zinc, Cast Iron, Copper, and other Metals."—23rd August; 6 months.

GEORGE DICKINSON, of Wood Street, Cheapside, in the City of London, Paper Manufacturer, for "An Improvement or Improvements upon Steam Engines."—23rd August; 6 months.

ARTHUR DUNN, of Stanford Hill, in the County of Middlesex, Gentleman, for "Certain Improvements in the manufacture of Soap."—24th August; 6 months.

JOHN COOPE HADDAN, of Bazing Place, Waterloo Road, in the County of Surrey, Gentleman, for "Certain Improvements in the construction of Carriages to be used on Railways, and of the method of forming the same into Trains."—25th August; 6 months.

HENRY KNILL, of Eldon Place, Bermondsey, for "Improvements in Cleansing the Bottoms of Docks, Rivers, and other waters."—30th August; 6 months.

JOHN GRAFTON, of Cambridge, Civil Engineer, for "Certain Improvements in the Construction of Retorts, and other Machinery for Making Gas from Coal and other Substances"—30th August; 6 months.

JOSEPH DAVIES, of Nelson Square, in the county of Surrey, Gentleman, for "A Composition for Protecting Wood from Flame."—30th August; 4 months.

WILLIAM DOLIER, of Liverpool, in the county of Lancaster, Lecturer on Education, for "A Certain Durable Surface or Tablet for the Purpose of receiving Writings, Drawings, or Impressions of Engravings, or other Devices, capable of being Printed, which Surface may be applied for Roads or Pavements, and part of which Invention may also be used as the Means of Strengthening or Beautifying Glass."—30th August; 6 months.

MILES BERRY, of 66, Chancery Lane, Patent Agent, for "Certain Improvements in Looms for producing Metallic Fissures, and also Improvements in such Fissures applicable to the Making of Buttons, Epaulettes, Tassels, and other purposes, for which Gold and Silver Lace, or Braiding is commonly employed, and to the Making of Imitations of Jewellery and other Fancy Articles."—30th August; 6 months.

LAWRENCE HEYWORTH, of Yewtree, near Liverpool, Merchant, for "A new Method of Employing Steam Power directly to the Periphery of the Movement Wheel, for the purposes of Locomotion, both on Land and Water, and for Propelling Machinery."—30th August; 6 months.

JOHN EARLE HUXLEY, of Great Marlborough Street, JOHN EARLE HUXLEY, jun., of the same place, and JOHN OLIVER, of Dean Street, Soho, Stove Makers, for "Improvements in certain descriptions of Stoves."—31st August; 6 months.

WILLIAM JOSEPH CURTIS, of Stamford Street, Blackfriars Road, Civil Engineer, for "Certain improved Machinery and Apparatus for facilitating travelling and transport on Railways, parts of which are also applicable to other Purposes."—31st August; 6 months.

NOTICES TO CORRESPONDENTS.

We have received a communication from Mr. Davy, complaining of our remarks in the last month's Journal relative to his drawing of the Tower and Spire of St. Vedast, exhibited at the Royal Academy. If we are not sufficiently explicit in our comments, we are sorry for it. Our opinion is, that drawings otherwise than original designs, ought not to be exhibited in the Architectural Room, excepting under very particular circumstances. Mr. Davy alludes to our remarks relative to "The Loggia of the Villa Madama," designed by Mr. Moore, and says that that drawing is not a whit more original than his. True, it may be so; but we consider that as a truly beautiful *artistic* drawing, exhibiting great judgment and taste in the perspective and colouring; which is not the case with Mr. Davy's drawing. In making this remark we do not mean to deny that Mr Davy's drawing is very accurately executed, and that very great labour has been bestowed in ascertaining the measurement of the Tower, "from the vane to the base." We should not have the slightest objection to see a room in the Academy set apart for drawings of this description, that students might have an opportunity of studying *construction*, which we consider a most important part of the studies of an Architect; but as long as the exhibition of Architectural Drawings is confined to one small room, we must protest against the introduction of any drawings, excepting original designs.

We have not space to insert Mr. Parker's communication. We shall be happy to hear from him on some other subject.

We are obliged to a correspondent for two pamphlets relative to Girard College, now erecting at Philadelphia. We had intended to notice them in the present Journal, but we have been obliged to postpone our extracts until next month; this is also the case with the reports of the Carlisle and Glasgow Railway, and the Glasgow and Ayr Railway Reports, and some other communications.

We must refer "An Architect" for the information he requires, to the Literary Gazette, where notice of Messrs. Gwilt's scheme first appeared.

The letter of W. L. B. on Friction-wheel Carriages, is in type, but postponed for want of room.

Communications should be sent on or before the 20th inst.; (not the 25th, as stated by mistake in last number) *if accompanied with drawings, still earlier.*

The publication of our twelfth number reminds us of our intention to complete the first volume of the Journal in December next; when an index and title page will be supplied, price 6d.

OBSERVATIONS ON BRICK BOND.

OBSERVATIONS ON BRICK BOND,

AS PRACTISED AT VARIOUS PERIODS; CONTAINING AN INVESTIGATION OF THE BEST DISPOSITION OF BRICKS IN A WALL, FOR PROCURING THE GREATEST POSSIBLE STRENGTH; WITH FIGURES REPRESENTING THE DIFFERENT MODES OF CONSTRUCTION.

[The following Observations were published in the form of a pamphlet, in 1805; we understand that they were from the pen of Mr. G. Saunders, a highly respectable member of the profession. They appear to us of a nature particularly valuable to the student; and as they have been for some time out of print, we are induced to re-publish the pamphlet entire. A copy of the work has been obligingly furnished to us by Mr. Donaldson, the Honorary Secretary of the Royal Institute of British Architects.]

Introduction.

The strength of a brick-wall depending very much on the arrangement of the materials, a clear investigation of the best mode becomes a consideration of importance. The following observations are presented with a view of engaging general attention to the subject, under the full conviction, that, as a matter of public utility, every one must feel an interest in promoting the intended object.

Figures are given of different modes that are, or have been practised; which, for the greater convenience of comparison, are delineated together on one page.

Observations, etc.

When two contiguous bricks have a third opposed to the joint that is between them, a part of the third being against one of the two first, and the remaining part against the other, a connexion is formed between the three bricks, tending to confine them to their respective situations, and is called *bond*.

Stretching bond is where the longitudinal direction of the bricks is parallel with the face of the wall, and consequently presents the whole length of the bricks on the outside.

Heading bond is where the longitudinal direction of the bricks makes a right angle with the face of the wall, and consequently presents the ends of the bricks on the outside.

Old English bond is a continuation of one kind throughout the same course, or horizontal layer: the courses are alternately all of stretchers; and all of headers; see Fig. 1 and 2. The stretching courses bind the parts of the wall together in the longitudinal direction, and the heading courses bind them in the transverse direction: it is chiefly on this account that old English brickwork is remarked not to separate at the joints; but when a fracture occurs, by its being greatly undermined, it breaks as any other solid body, such as stone of one piece would do. It is easy to conceive that a wall constructed in this mode must have considerable strength, for the parts of a wall are less liable to separate the longer the bonds are: the bonds are greatest in he longitudinal direction of the bricks, for then one brick may be four nches in length against each of two others in the same course; which is the tength that must be moved before they can separate without breaking.*

What is called *Flemish bond*, see Fig. 7, 8, 9, &c. consists in the disposition of the bricks on the outside, or face work, so that in the same course there shall be alternately a stretcher and a header: this mode was introduced, together with other Dutch fashions, about the reign of William and Mary, as may be ascertained by observing the works of brick prior and subsequent to that period. Strength was then sacrificed to a minute difference in the outside appearance; and bricks of two qualities were fabricated for the purpose; a fine brick, often to be rubbed and laid in what is called a close putty joint, for the exterior; and an inferior coarse brick for the interior substance of the wall: as these did not correspond in thickness, the exterior and interior of the wall could not be otherwise connected together than by an outside heading brick that was here and there continued of its whole length, where the exterior and interior courses happened to admit of it, which might not occur for a considerable space. The evil increased so far, that walls are found to consist of two separate outside faces of four inches each in thickness; and the interior substance of little better than rubbish. Yet the practice of using Flemish bond has continued ever since, and workmen are now become estranged from any other, except in a few accidental instances.

Not aware from whence the evil proceeds, considerate bricklayers have projected various schemes for obviating the defects in working with Flemish bond: these defects are, in one or both faces, bulging away from the interior substance; or the failure of the wall, by its separating into two thicknesses along the middle, which sometimes takes place when there is a great superincumbent weight on it, and is called splitting; this is the great terror of a bricklayer. To prevent the evil some lay laths, or the iron of hoops occasionally, in the horizontal joints between two courses: others lay diagonal courses of bricks at certain heights from each other; but the good effect of this last mode is much doubted, as in the diagonal course, by not being continued to the outside, the bricks are much mangled where strength is wanted. Others again lay all heading courses within the outside Flemish bond, a practice in great repute, making the face work alternately of nine and of four inches in thickness (see Fig. 3 and 4); this, as far as relates to the splitting of the wall, is an effectual preventive; but in curing one evil another is increased, for here is no stretching bond; the little that occurs in Flemish bond face work being too trifling to be of any avail: so that the least inequality of settlement, or weight, in the longitudinal direction of the wall, occasions a separation at the vertical joints, as may be often seen in the fronts of buildings: even if longitudinal courses should be directed to be alternately laid in the interior of the wall, there is little chance of succeeding better. In Fig. 5 and 6, the interior bricks are disposed with attention to combine complete bond as much as possible with Flemish facings, under the most favourable circumstance, the Flemish facings being only on one side of the wall: this at the best falls short of the quantity of bond produced in the old English manner; and although master bricklayers generally wish to have their work well done, few would expect this intricate disposition of the bricks to be followed in many yards of work, where the adjustment of the bricks in one course depends upon the position of those in the course beneath, for the under course requires to be seen or recollected. When the Flemish facings occur on both sides of the wall, they furnish no indication of the interior adjustment, for every course is similar on the outside. The interior of the under course is not seen, on account of being covered with mortar for the bed of the next course; and to recollect how every brick was laid beneath is more than can be expected from men who are dispatching work, and moving to distant parts in the performance of it. The work will, by inadvertence, approach that represented in Fig. 7, 8, and 9, producing continued joints that divide the wall into several thicknesses, where the separation, or splitting as it is termed, usually takes place. In the old English bond, a workman cannot easily lose his way; for the outside of the last course shows him how the next is to be laid. It may be also observed that in the same course there cannot be both stretching and heading bond with complete effect throughout one line of wall; for wherever the stretching bond is crossed by the heading bond, the continuity and effect of stretching bond is destroyed; therefore the mixed position of the bricks, represented in Fig. 10 and 11, will not answer, and it often produces a perpendicular joint in the middle of the thickness, dividing the substance into two walls.

The outside appearance is all that can be advanced in favour of Flemish bond; of this, however, opinions are far from being in accord: of those who have considered the subject, some allege, that if the courses were alternately of stretchers and of headers, which is the old English bond, executed with the same neatness usually shewn in Flemish bond, it would be equally, or more pleasing. It is of great importance that all concerned in directing the construction of brick walls should urge the rejection of the Flemish fashion.* The difference between the Flemish and the old English bond in the outside appearance, is really too minute to be observed by the generality of people: and even those who are in the constant habit of examining such works, must look closely at them, before they can make the distinction. Bricklayers of credit will readily follow the old English practice, as it is the easiest to be executed, and occasions no extraordinary waste; the only directions required to be given are these:

Each course is to be alternately of stretchers and of headers.

Every brick in the same course is to be laid in the same direction; but in no instance is a brick to be placed with its whole length along the side of another: but to be so situated, that the end of one may reach to the middle of the others that lie contiguous to it; except in the outside of the stretching course, where three quarter bricks necessarily occur at the ends to prevent a continued upright joint in the face work.

A wall which crosses at a right angle with another, will have all the bricks of the same level course, in the same parallel direction, which completely bonds the angles. See Figs. 1 and 2.

* The ancient Roman bond is, in principle, the same as the old English bond. The Roman walls that now remain are generally of great thickness, and have three, or sometimes more, courses of brick laid at certain intervals of the height, stretchers upon stretchers; and *vice versa* opposite the return walls, and sometimes at certain distances in the length, forming piers that bind the wall together in the transverse direction; the intervals between these piers of brick are filled up, and form panels of rubble or reticulated work; consequently great substance with strength was economically obtained.

* The Act of Parliament which regulates the size of bricks, directs that they shall not be less than 8½ inches in length, 4 inches in breadth, and 2½ inches in thickness. The brickmakers now make their moulds to produce bricks of that size. The breadth of two bricks together, with one vertical joint, should be equal to the length of a brick; the vertical joint must therefore be half an inch in thickness, according to the present make of the bricks, which is too much for neat work. The framers of the Act undoubtedly had respect to the accustomed mode of reckoning the thickness of a wall by so many bricks; or so many times nine inches as the thickness of the wall contained; which, allowing a quarter of an inch, as being ample for a vertical joint, requires the brick to be 8¾ inches in length, and 4¼ inches in breadth, in order that two breadths together, with a quarter of an inch for the vertical joint, may be equal to the length of a brick. The size mentioned by the Act was probably for the purpose of making an allowance for any accidental variation that might occur in the burning of bricks; and the Act limited the smallest proportion that was to be admitted in such a case; but as advantage has been taken to make the bricks to the least size expressed in the Act, it is highly necessary that the limitation should be altered to what good brickwork requires, viz. 8¾ inches in length, 4¼ inches in breadth, and 2½ inches in thickness.

REVIEWS.

Geology as a Science applied to the Reclamation of Land from the Sea, the Construction of Harbours, the Formation of Railways, and the Discovery of Coal, with an assumed outline Map of the Granite Formation of the Earth. By John Rooke, Esq. London: Ridgway. 1838.

It may be considered, as a step in the progress of engineering science, that it should be thought susceptible of an immediate application of Geology to its purposes, and we hail with pleasure the appearance of the present work. The object of it is first to elucidate the general formation of the earth, on simple principles, and then to show the application of engineering to the surface of the British Islands. In carrying out these objects, the author proceeds on a different course from those generally received, and although it is not compatible with our objects to enter into his general theory, we can say that there is much in it which bears the stamp of truth and reason. His theory is that of a Neptunian formation, by a great tidal wave, which he supposes to be at present in activity, although on a diminished scale. Attached to his work is a sketch of the great tidal basin of the Atlantic, surrounded with a granitic chain of mountains, containing the greater part of the land and depositions of the globe, and one half of the population, with the great tidal vortex, the north pole, and the magnetic poles in Siberia and the Gulf of Boothia. This presents an accumulation of the physical features of the globe, which cannot be thus assembled without some immediate and definite connexion.

However, our object being more with the professional part of the work, we must leave the philosophic portion, and come to what is more immediately within our sphere. Having shown the formation of the oceanic basins in the 5th chapter, he proceeds to consider the formation of harbours on the English coasts. After an examination of the action of the tides and their tendency to deposit itself on particular points, he proceeds to consider the several positions on the north-west coast, the Wash, and the Thames.

The different estuaries on the coasts of Lancashire and Cheshire may be estimated at 200,000 acres in extent. Namely—

In the Dee	36,000 acres.
— Mersey	27,000 „
— Ribble	28,000 „
In Morecambe Bay	96,000 „
In the Duddon	13,000 „
Total	200,000 acres.

Showing this extent of ground dry at low water, he proceeds to recommend its reclamation by the diversion of the several land streams which flow over it. Mr. Rooke thus alludes to the proceedings of the River Dee Company :—

Having said thus much on the estuaries of the Mersey and the Ribble, it need be remarked on the Dee only, that the embankment company there formed have commenced their works at the wrong end. Instead of co-operating with the tidal action of the estuary, they work against it, and in some measure fail in reaping the highest results attainable to both navigation and themselves. In place of amending the navigable channel, which, by starting at the point of Air on the south, and at Little Meoles on the north, they would have been sure to do, as well as gaining the most land, their unskilful proceedings have ruined Chester as a port.

With regard to the reclamation of Morecambe Bay, which now attracts great attention in the north of England, the author observes :—

Means of diverting the great central stream of the Bay to either of its sides, and finally carrying the body of water to the verge of the Irish Sea, would evidently convert those waters into the instrument required. So placed, their volume and force would then contribute to break a powerful flux in the Irish Sea, and leave no cause of return to the vast masses of silt which the flowing tide propels into the area of the Bay, but which the central stream is continually forcing out to sea again. In the course of two years depositions have been known to form on an area as much as 20 square miles in extent, and from five to eight feet in depth, even under the sweeping influence of this great central stream of backwater, which we should purpose carrying on the northern line of the Bay, or more full consideration might decide in turning it southwards into the river Lune. It may be asked, indeed, why not embank the sea at once? We should answer that such a work would seem impracticable; and if it were practicable, a vast extent of low lying and almost worthless silicious beds would not repay the cost of embankment so well as reclaimed land silted over on right principles; an objection which silting up fully answers. * *

Sandy materials being naturally the first deposited, and finer and lighter materials being borne further on land, so they remain on the surface, where self-reclamation is adopted, and form a fruitful super-soil. Hence, fine and fertile particles, which vast inland drains are constantly driving into Morecambe Bay, would be assorted from barren ones, by a tidal process, and undergo deposition the uppermost. In all alluvial tracts of country, this law of deposition is manifest, and is a reason why alluvian affords so much fertile land. Mere sands embanked and reclaimed at once, can seldom afford land of much value. * *

So weighty a body of water as the rivers Ken, Leven, and Duddon, emptying themselves into Fowdry and its channels, could not fail in occasioning a powerful scour within, and on the entrances of this vast and secure roadstead. Nor is this all. The very steps which are favourable to the acquisition of such an object, are equally adapted to the reclamation of Morecambe Bay, and the estuary of the Duddon from the Sea. Preparing the way for the construction of a line of railroad that would give a speedy and easy communication between Cumberland on the north, and Lancashire on the south. Opening out at the same time a direct route of railroad, between the south of Scotland, through the west of Cumberland, and the south of England; embracing in a comprehensive plan national objects of vast importance, attainable only by the means here advocated, and through the portions of the kingdom just described. * *

In casting the eye on the vast attainable acquisitions which appear on the coasts of Lancashire and Cheshire, in the estuary of the Solway Frith, that of the Wash, and the Thames, they may be viewed as objects of great national importance. The mere reclamation of land from the sea is not the sole consideration, but the facility and security of navigation on one-third of our English shores, besides giving the cheapest and best direction to railroads, and thereby effecting the most speedy communications between the different parts of the empire. We may be well allowed to express some surprise that national attainments so important should have been so far neglected, the more especially as they offer to the speculator ample and sure returns of profit, and might well rouse the attention of government and the legislature. Now that railroads have become essential to the preservation of our high station among the various nations of the earth; as Morecambe Bay and the Solway Frith, sever almost the inland communications of England, Scotland, and Ireland, they surely claim intense national interest. Not overlooking at the same time the grievous consequences of a false direction given to capital in the construction of railways on lines where the cost is enormously high, undulations and curves exceedingly objectionable, the working powers expensive, and the communications from some parts of the empire to others tardy and dangerous; even passing through sections of the kingdom all but barren, avoiding the fruitful plains, manufacturing workshops, and commercial storehouses of north Lancashire, and western Cumberland.

Upon the means of removing Tynemouth Bar at the entrance of the river Tyne, there are the following remarks :—

On ordinary principles of physics it is obvious that a river crossing a tide-wave suddenly, or at right angles, must occasion a bar; while two angles running on slow progressions into each other, must contribute materially to obviate the objection, and give the desideratum sought for, a flowing stream from an inland drain, working conjointly with a flowing tide, so that a deposition of silt no longer occurred in the extreme angle of their junction. For two currents crossing each other at right angles, of which the deposition of the south-east section of our island is a striking illustration, have a tendency to drive each o'her away, and necessarily place a line of sedimentary depositions between them. Hence the Strait of Dover is kept open by an eastern and western tide-wave abutting on the coast of France.

In the 6th chapter, investigating the most favourable lines for Railways, is given the following opinion :—

Geology points out the leading features of the ground on which it is proposed to construct these several lines of railway. As the different formations of which our island is composed have been chiefly deposited by currents which have flowed from north-east to south-west, it is obviously a general rule, that following the courses of these currents must contribute to cheapen the formation of railways, and facilitate locomotion, much more than going transversely over them, or from north-west to south-east; and it must prove still more difficult and disadvantageous to cross the Penine chain of hills in the north of the kingdom, where either the secondary or the tertiary formations abound, until the red sandstone group appears. * * We find beside a series of plans which stretch from the basin of London and Bristol, to the Solway Frith, and lying on the western borders of the kingdom. A similar plain is extended along the eastern borders of the kingdom from the London basin to Newcastle-upon-Tyne. * *

It is comparatively easy to obtain an advantageous line from Newcastle-upon-Tyne to London; from London to Cheltenham by the valley of the Thames, with a lateral branch to Bristol, and the south-west counties of England generally. From Cheltenham a plain also runs directly northwards as far as Dumfries and Carlisle, by the valleys of the Severn and the Weaver, along the vast levels of the red sandstone group, and by the diluvial and alluvial depositions on the west of Lancashire, across Morecambe Bay, the estuary of the Duddon, and by the western shore of Cumberland across the Solway Frith to Dumfries, and laterally to Carlisle. The entire track of this great line of continuous levels is scarcely undulating, on a low general level, and remarkably straight, considering its length and the varied directions of its lines.

Mr. Rooke objects particularly to the course of the Birmingham Railway, and at great length urges the preference of a line by Cheltenham, Worcester, and Wolverhampton, to Liverpool.

The vital error of carrying railroads across geological ribs of iron, in preference to traversing smooth and plastic plains, where nature cheers art

onwards in every form, is manifest, cannot be denied, and is sure to be remedied in due season. In a day when millions of money are either in course of expenditure on railways through almost every part of the kingdom, or projected, general levels ought to be taken forthwith, and the most advantageous lines ascertained. * *

No sooner are we across the river Mersey northwards, than we find an unbroken plain extended from Warrington to Preston and Lancaster. Here the question arises of crossing Morecambe Bay on the one hand, or scaling the vast and continuous primary Isle of Cumberland and Westmorelond on the other. * *

A railroad is certain to be completed on the line here marked out, regardless of the previous follies of any rival company whatever. From London to Dumfries, by the valleys of the Thames, the Severn, and the Weaver, with the plains of Lancashire and western Cumberland in continuation, leading across the Solway Frith to Tordiff Point, presents the longest chain of level ground and straight lines of which our island may boast. Not to say the wealth, the manufactures, the commerce, and marine affairs which lie upon and touch this great line of levels. Nor is this all.

Viewing the line here traced out as a common base to numberless ascending vales, a denial of our proposition might seem a denial of all just rules of science and common fairness. For the geological reasons assigned, central England ought to be turned rather than crossed, and its rugged undulations and sharp curvatures avoided as much as may be.

As a temporary line to Glasgow, which might be worked in less than thirty hours, the author recommends Mr. Hyde Clarke's plan, of proceeding by the Birmingham, Grand Junction, and Preston and Wyre Railways to Wyreton, thence by steam-boat to Wigton Bay, and thence to join the Glasgow and Paisley Railway at Ayr.

We regret that it is not in our power to go farther into a work which abounds so much with local detail, as to render it almost impossible to detach any particular part. There is much valuable information and criticism on the railways and harbours in the north of England, and much light thrown as well upon the local incidents, as upon the general laws by which they are regulated. To the professional reader it cannot fail to afford much information, while it is equally interesting to the philosopher or the agriculturist. A considerable portion is devoted to a discussion on the formation of the coal beds, in illustration of the prevailing theory of their being composed of wood drift. In conclusion, we earnestly recommend to the reader to judge for himself, and he will find this work the more useful, as its portable contents are devoted principally to our country, and not to any discursive geological discussion.

Perspective Simplified, or the Principles of the Art, as laid down by Dr. Brook Taylor, familiarly Illustrated. By Z. Laurence. With nine Plates. 8vo. London: 1838.

Perspective is a science so fixed by the mathematical laws of vision, as to admit of no fresh discoveries being made in it, no new principles established, notwithstanding that Mr. Parsey plumes himself not a little upon having made what he considers a most notable discovery,—namely, that vertical lines visibly converge, and ought to be so represented; that is, the upper part of a lofty building, as he contends, should be narrower in a drawing than its breadth at the level of the eye. How many converts he may have is best known to himself, for we have not yet seen any practical application of his valuable discovery, and will venture to say that we never shall. Neither do we find that Mr. Laurence has even so much as mentioned it, although he speaks of several treatises on the subject in his preface, where he very sensibly remarks: "The main improvement that suggested itself to me, was *concentration; to concentrate* the subject into a few of the most essential theorems and problems, applying them to plain examples illustrated in the most familiar manner."

Undoubtedly such is the case, for the study has been so overlaid with rules, intended to meet every possible case which may arise, that most persons feel alarmed, if not bewildered, at the very outset. Yet, on the other hand, too little may be attempted no less than too much, the consequence of which will be, that for want of a full, as well as *familiar* explanation, the student will still remain at a loss, and not know how to proceed, when he comes to apply the rules by himself. Accordingly, however briefly the rules may be laid down, they ought to be accompanied by such remarks as may tend to impress them on the memory, and to show how the very same principle applies to a variety of cases apparently very different, yet in reality alike, as far as principles are concerned. To be brief, is not always to be familiar in explanation; neither is to be familiar, invariably to be exact and intelligible: and this, we are compelled to observe, is in some degree the case with Mr. Laurence. Consequently his book requires to be studied with the utmost attention and reflection on the part of the reader who brings to it no previous acquaintance with the subject. So far it is rather a compendium than a simplification of the principles laid down; as such an abridgment we can recommend it, and certainly as a work entirely free from that mystification which, whether intentional or not, stamps many other treatises professing to have the same object.

A Dictionary of Arts, Manufactures, and Mines; containing a clear Exposition of their Principles and Practice. By Andrew Ure, M.D. To be completed in Ten Monthly Parts, with upwards of 1000 Engravings on Wood. Part I, 8vo. London: Longman and Co. 1838.

From the specimen before us, this appears likely to be a valuable work, which not only treats of the application of chemistry to the arts and manufactures; but it also enters very fully into the mechanical arrangement of the buildings, the plants, and implements of a great variety of trades, on which it communicates much lucid and well arranged information. It is compiled with great care, and besides containing the latest materials is strictly confined to what is useful, without superfluous detail. In the present part are some few articles which more immediately bear upon our pursuits, and in that on alabaster are some interesting particulars relative to the curious carbonic spring of San Filippo, in Tuscany, where works of artificial alabaster are produced.

We extract the article on Artesian Wells, which contains a compendium of information on this interesting subject, now exciting considerable attention in many districts of the metropolis.

Artesian Wells.—Under this name is designated a cylindrical perforation, bored vertically down through one or more of the geological strata of the earth, till it passes into a porous gravel bed containing water, placed under such incumbent pressure as to make it mount up through the perforation, either to the surface or to a height convenient for the operation of a pump. In the first case, these wells are called spouting or overflowing. This property is not directly proportional to the depth, as might at first sight be supposed, but to the subjacent pressure upon the water. We do not know exactly the period at which the borer or sound was applied to the investigation of subterranean fountains, but we believe the first overflowing wells were made in the ancient French province of Artois, whence the name of Artesian. These wells, of such importance to agriculture and manufactures, and which cost nothing to keep them in condition, have been in use, undoubtedly, for several centuries in the northern departments of France, and the north of Italy; but it is not more than fifty or sixty years since they became known in England and Germany. There are now a great many such wells in London and its neighbourhood, perforated through the immensely thick bed of the London clay, and even through some portions of the subjacent chalk. The boring of such wells has given much insight into the geological structure of many districts.

The formation of Artesian wells depends on two things, essentially distinct from each other: 1. On an acquaintance with the physical constitution, or nature, of the mineral structure of each particular country; and, 2. On the skilful direction of the processes by which we can reach the water level, and of those by which we can promote its ascent in the tube. We shall first treat of the best method of making the well, and then offer some general remarks on the other subjects.

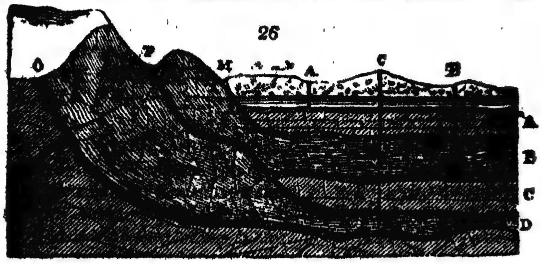
The operations employed for penetrating the soil are entirely similar to those daily practised by the miner, in boring to find metallic veins; but the well excavator must resort to peculiar expedients to prevent the purer water, which comes from deep strata, mingling with the cruder waters of the alluvial beds near the surface of the ground, as also to prevent the small perforation getting eventually filled with rubbish.

The cause of overflowing wells has been ascribed to a variety of circumstances. But, as it is now generally admitted that the numerous springs which issue from the ground proceed from the infiltration of the waters progressively condensed in rain, dew, snow, &c., upon the surface of our globe, the theory of these interior streamlets becomes by no means intricate; being analogous to that of syphons and water jets, as expounded in the treatises of physics. The waters are diffused, after condensation, upon the surface of the soil, and percolate downwards, through the various pores and fissures of the geological strata, to be again united subterraneously in veins, rills, streamlets, or expanded films, of greater or less magnitude, or regularity. The beds traversed by numerous disjunctions will give occasion to numerous interior currents in all directions, which cannot be recovered, and brought to the day; but when the ground is composed of strata of sand, or gravel very permeable to water, separated by other strata nearly impervious to it, reservoirs are formed to our hand, from which an abundant supply of water may be spontaneously raised. In this case, as soon as the upper stratum is perforated, the waters may rise, in consequence of the hydrostatic pressure upon the lower strata, and even overflow the surface in a constant stream, provided the level from which they proceed be proportionally higher.

The sheets of water occur principally at the separation of two contiguous formations; and, if the succession of the geological strata be considered, this distribution of the water will be seen to be its necessary consequence. In fact, the lower beds are frequently composed of compact sandstone or limestone, and the upper beds of clay. In level countries, the formations being almost always in horizontal beds, the waters which feed the Artesian wells must come from districts somewhat remote, where the strata are more elevated, as towards the secondary and transition rocks. The copious streams con-

densed upon the sides of these colder lands may be therefore regarded as the proper reservoirs of our wells.

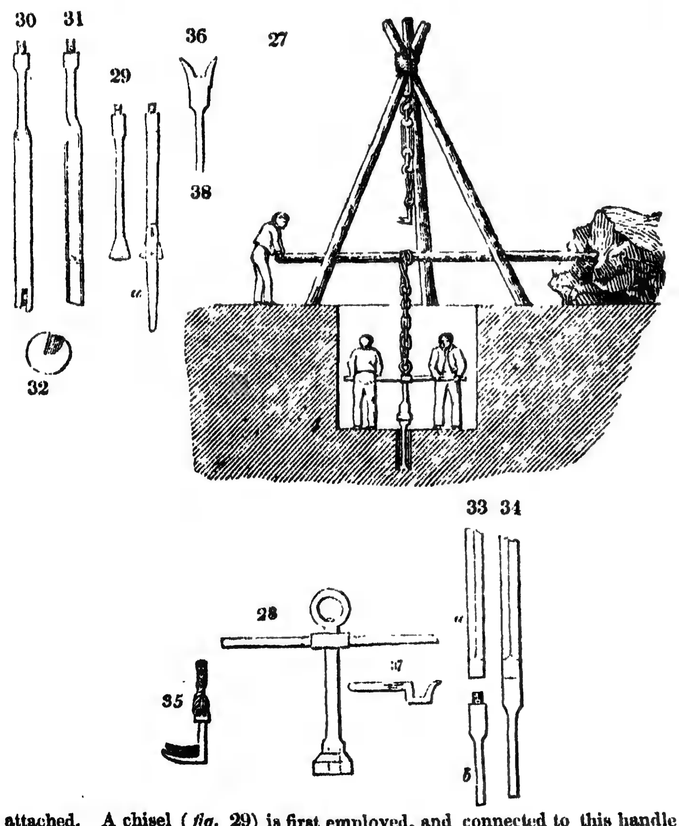
Fig. 26 represents the manner in which the condensed water of the



heavens distributes itself under the surface of our globe. Here we have a geological section, showing the succession of the several formations, and the sheets or laminæ of water that exist at their boundaries, as well as in their sandy beds. The figure shows also very plainly that the height to which the water re-ascends in the bore of a well depends upon the height of the reservoir which supplies the sheet of water to which the well is perforated. Thus the well A, having gone down to the aqueous expanse *a a*, whose waters of suppy are derived from the percolation M, will afford rising waters, which will come to the surface; whilst in the well B, supplied by the sheet P, the waters will spout above the surface, and in the well C they will remain short of it. The same figure shows that these wells often traverse sheets of water, which rise to different heights. Thus, in the well C there are five columns of ascending waters, which rise to heights proportional to the points whence they take their origin. Several of these will be spouting or overflowing, but some will remain beneath the surface.

The situation of the intended well being determined upon, a circular hole is generally dug in the ground, about six or eight feet deep, and five or six feet wide. In the centre of this hole the boring is carried on by two workmen below, assisted by a labourer above, as shown in *fig.* 27.

The handle (*fig.* 28) having a female screw in the bottom of its iron shank, with a wooden bar or rail passing through the socket of the shank, and a ring at top, is the general agent to which all the boring implements are to be



attached. A chisel (*fig.* 29) is first employed, and connected to this handle by its screw at top. If the ground is tolerably soft, the weight of the two workmen bearing upon the cross bar, and occasionally forcing it round, will soon cause the chisel to penetrate; but if the ground is hard or strong, the workmen strike the chisel down with repeated blows, so as to peck their way, often changing their situation by walking round, which breaks the stones, or other hard substances, that may happen to obstruct its progress.

The labour is very considerably reduced, by means of an elastic wooden pole, placed horizontally over the well, from which a chain is brought down, and attached to the ring of the handle. This pole is usually made fast at one end, as a fulcrum, by being set into a heap of heavy loose stones; at the other end the labourer above gives it a slight up and down vibrating motion, corresponding to the beating motion of the workmen below, by which means the elasticity of the pole in rising lifts the handle and pecker, and thereby very considerably diminishes the labour of the workmen. See *fig.* 27.

When the hole has been thus opened by a chisel, as far as its strength would permit, the chisel is withdrawn, and a sort of cylindrical auger (*fig.* 30) attached to the handle (*fig.* 28), for the purpose of drawing up the dirt or broken stones which have been disturbed by the chisel. A section of this auger is shown in *fig.* 31, by which the internal valve will be seen. The auger being introduced into the hole, and turned round by the workman, the dirt or broken stones will pass through the aperture at bottom (shown at *fig.* 32), and fill the cylinder, which is then drawn up, and discharged at the top of the auger, the valve preventing its escape at bottom.

In order to penetrate deeper into the ground, an iron rod, as *a*, *fig.* 33, is now to be attached to the chisel, *fig.* 29, by screwing on to its upper end, and the rod is also fastened to the handle, *fig.* 28, by screwing into its socket. The chisel having thus become lengthened, by the addition of the rod, it is again introduced into the hole; and the operation of pecking or forcing it down, is carried on by the workmen as before. When the ground has been thus perforated, as far as the chisel and its rod will reach, they must be withdrawn, in order again to introduce the auger, *fig.* 30, to collect and bring up the rubbish; which is done by attaching it to the iron rod, in place of the chisel. Thus as the hole becomes deepened, other lengths of iron rods are added, by connecting them together, as *a b* are in *fig.* 34. The necessity of frequently withdrawing the rods from the holes, in order to collect the mud, stones, or rubbish, and the great friction produced by the rubbing of the tools against its sides, as well as the lengths of rods augmenting in the progress of the operation, sometimes to the extent of several hundred feet, render it extremely inconvenient, if not impossible, to raise them by hand. A tripedal standard is, therefore, generally constructed by three scaffolding poles tied together, over the hole, as shown *fig.* 27, from the centre of which a wheel and axle, or pair of pully blocks is suspended, for the purpose of hauling up the rods, and from which hangs the fork, *fig.* 35. This fork is to be brought down under the shoulder, near the top of each rod, and made fast to it by passing a pin through two little holes in the claws. The rods are thus drawn up, about seven feet at a time, which is the usual distance between each joint, and at every haul a fork, *fig.* 36, is laid horizontally over the hole, with the shoulders of the lower rod resting between its claws, by which means the rods are prevented from sinking down into the hole again, while the upper length is unscrewed and removed. In attaching and detaching these lengths of rod, a wrench, *fig.* 37, is employed, by which they are turned round, and the screws forced up to their firm bearing.

The boring is sometimes performed for the first sixty or a hundred feet, by a chisel of 2½ inches wide, and cleared out by a gouge of 2¼ diameter, and then the hole is widened by a tool, such as is shown at *fig.* 38. This is merely a chisel, as *fig.* 29, four inches wide, but with a guide, *a*, put on at its lower part, for the purpose of keeping it in a perpendicular direction; the lower part is not intended to peck, but to pass down the hole previously made, while the sides of the chisel operate in enlarging the hole to four inches. The process, however, is generally performed at one operation, by a chisel of four inches wide, as *fig.* 29, and a gouge of three inches and three quarters, as *fig.* 30.

It is obvious, that placing and displacing the lengths of rod, which is done every time that the auger is required to be introduced or withdrawn, must, of itself, be extremely troublesome, independent of the labour of boring; but yet the operation proceeds, when no unpropitious circumstances attend it, with a facility almost incredible. Sometimes, however, rocks intercept the way, which require great labour to penetrate; but this is always effected by pecking, which slowly pulverises the stone. The most unpleasant circumstance attendant upon this business is the occasional breaking of a rod into the hole, which sometimes creates a delay of many days, and an incalculable labour in drawing up the lower portion.

When the water is obtained in such quantities and of such quality as may be required, the hole is dressed or finished by passing down it a diamond chisel, funnel mouthed, with a triangular bit in its centre, this makes the sides smooth previous to putting in the pipe. This chisel is attached to rods, and to the handle, as before described; and, in its descent, the workmen continually walk round, by which the hole is made smooth and cylindrical. In the progress of the boring, frequent veins of water are passed through; but, as these are small streams, and perhaps impregnated with mineral substances, the operation is carried on until an aperture is made into a main spring, which will flow up to the surface of the earth. This must, of course, depend upon the level of its source, which, if in a neighbouring hill, will frequently cause the water to rise up, and produce a continued fountain. But if the altitude of the distant spring happens to be below the level of the surface of the ground where the boring is effected, it sometimes happens that a well of considerable capacity is obliged to be dug down to that level, in order to form a reservoir, into which the water may flow, and whence it must be raised by a pump; while, in the former instance, a perpetual fountain may be obtained. Hence, it will always be a matter of doubt, in level countries, whether water can be procured, which would flow near to or over the surface; if this cannot be effected, the process of boring will be of little or no advantage, except as an experiment to ascertain the fact.

In order to keep the strata pure, and uncontaminated with mineral springs, the hole is cased, for a considerable depth, with a metallic pipe, about a quarter of an inch smaller than the bore. This is generally made of tin (though sometimes of copper or lead) inconvenient lengths; and, as each length is let down, it is held by a shoulder resting in a fork, while another length is

soldered to it; by which means a continuous pipe is carried through the bore, as far as may be found necessary, to exclude land springs, and to prevent loose earth or sand from falling in, and choking the aperture.

Under the head of "Assay" is a curious illustration of the uncertainties of this operation, in a table of the experiments of European assayists, on some silver sent to them from the Paris Mint. The variation between the several results is as much as 14 per 1000, and in only two instances have they approached within one per mille of the true result. The article on "Beer" contains an account of the plant, and the several implements necessary in a brewery, and a description of the large establishments in London. The present part promises well for the utility of the work, and we shall no doubt be able to avail ourselves of something in the ensuing parts.

The Practice of Making and Repairing Roads; of constructing Footpaths, Fences, and Drains; also, a Method of comparing Roads with reference to the Power of Draught required, &c., &c. By Thomas Hughes, Esq., Civil Engineer. London: John Weale, 1838.

This is a useful, cheap, and practical work on road-making, and well suited to the wants of the engineering student. Mr. Hughes has condensed into a small space the results of his experience; which are, as might be expected, valuable, as he was engaged under the late Mr. Telford on the London and Holyhead road, as well as in several other parts of England and Scotland for many years.

The author endeavours to rouse the attention of the public to the necessity of improving our parish roads, which have for a length of time presented a most complete system of jobbing and mismanagement. The method of appointing the surveyor of the highways, in the country, has long required a change; and until this be effected, it is ridiculous to expect to have good roads. In most parishes, the system has been this; a surveyor is annually appointed, who may be perhaps a farmer, or perhaps a keeper of a chandler's shop. Immediately on his appointment, it is his first object to put into good repair the road leading to his farm, or to pave the footway in front of his shop, as the case may be; very desirable improvements doubtless, and naturally coming first of all under his notice. Nor is this all; his practice of road-making and mending is probably as rude, as his choice of spots to show his skill upon is arbitrary. It is ten to one that he will cart his gravel from the pits, and shoot it down at once upon the road, without any previous preparation of filling up the ruts and making a solid substratum. Such is the usual character of the parish surveyor; and if by chance a man is for once appointed who knows and cares to perform his duty, just as he begins to bring the roads into a tolerably good state, his term of office expires, and there steps into his place a successor of the usual character before described to derange and stultify all his proceedings. The result is, a state of the parish roads, well described in the following extract:—

The farmer, in conveying his corn and other produce to market, and in sending manure to his fields, may comfort himself with the reflection, that whilst his horses are on the turnpike-road they will not be injured by the loads they have to draw; but what is their situation until they reach the turnpike-road, and after they leave it? Of course, where the turnpike lies in such a direction as not to be available, the case will be worse than where it can be partially used. But even in the most favourable case, it is evident, that the farmer must be content with a much less load than his horses could draw on the turnpike-road, unless he attempt to carry more than a fair load on the bad roads to be passed over, leading into or out of the turnpike-road. On the other hand, if he puts on a fair load for the turnpike-road, his horses will be much overloaded when they come on the inferior kind of road; because a horse, which on the former is able to draw a ton weight with ease, would probably on the latter be unable to move with more than five or six hundred weight. The injurious effects of this are too obvious to require comment: and they establish a strong reason why all roads should be reduced, as nearly as possible, to an equality in point of draught. It could hardly be expected, nor is it necessary, that the same breadth and finish should be given to all roads, which are very properly adopted on the main lines of turnpike; but I am decidedly of opinion, that all roads ought to be equally hard and solid; and I would make every parish and every occupation or farm-road throughout this country, as excellent in this essential point as the great Holyhead road itself. For roads where no great traffic exists, the breadth is of little consequence; but on this kind of road the vehicles which do pass over it are usually farm waggons, containing as heavy weights as any on the turnpike-roads. The unfrequented routes should therefore be as capable of carrying heavy traffic as the great roads themselves; and this they can only be when formed with a firm unyielding foundation. * * Surveyors should be made to act on a fixed system, because the country has already sufficiently suffered from the ignorance and incapacity by which too many of this class are distinguished. Written instructions in the form of specifications should be drawn out by competent engineers, practically experienced in the construction and management of roads; and to these instructions, which should be adapted to particular districts of country, the surveyors should be bound strictly to adhere.

Not only do we concur in these recommendations, but we are even inclined to go further. For we do not expect that any good will be effected, till the whole race of parish surveyors are discharged, and all the roads of each county placed under the superintendence of an able and efficient engineer, who shall be held responsible for keeping them in good condition. He should have authority to appoint district surveyors to act under him; and to employ the poor of each parish on their own roads when it appears desirable. And all the highways should be repaired at the expense of the county, from the county rates.

Mr. Hughes has given in his second chapter some very useful directions for *improving an existing road*. We are not however favourable to giving so great a convexity to roads, as he here recommends.

As a first step to improve the condition of an old road, the direction and general levels of which cannot be altered, I should proceed to cut down high fences, if these exist, on each side of the road, and regularly to trim the hedges, so that the height of the bank and fence should not exceed four or five feet above the level of the road. The soft mud should then be scraped from the surface, and the bed of the road formed with a regular convexity of one inch in five feet, which will give in a road of thirty feet wide, a rise of nine inches in the centre. * * A very common opinion is, that the depth of material in the centre of the road should be greater than at the sides; but or my part, I have never been able to discover why the sides of the road should be at all inferior to the middle in hardness and solidity. On the contrary, it would be a great improvement in general travelling, if carriages could be made to adhere more strictly to the rule of keeping the proper side of the road; and the reasonable inducement to this practice is obviously to make the sides equally hard and solid with the centre. * * If equal labour and materials be expended on the whole breadth of the road, it is evident that the wear and tear will be far more uniform; and when any one part requires repair, the traffic may with safety be turned on to another part. Hence I should always lay on the same depth of material all over the road; and this alone will of course render it necessary to curve the bed of the road. * * The circle, with the circumference of which I would recommend that both the bed of the road and its upper surface should coincide, would be formed with a radius of 150 feet; and as a guide for the workman in making the proper section, it would be very useful to place in his hands a piece of board, having one of its edges curved to the proper figure, and this edge being applied to the road surface, will at once determine the correct degree of curvature.

Chapter IV. describes the various methods adopted for securing a good foundation for the *Highgate Archway Road*. Previously to Mr. Telford taking the superintendence, this road baffled all attempts of its constructors, principally owing to the want of a proper system of drainage, which is the most essential point to be attended to where roads are made through cuttings or on hill sides. Various kinds of foundations for the road were tried; in some parts, gravel or Thames ballast was mixed with cement, and moulded into the form of bricks; in others, the cement and ballast were mixed and spread over the road without moulding. But neither of these modes is considered by Mr. Hughes so good as a foundation formed of concrete composed of Thames ballast and lime.

With the view of affording a modern example in which lime concrete has been used, I would refer to the Brixton road, where a concrete composed of gravel and lime has been recently applied by Mr. Charles Penfold, surveyor to the trust. In this case the proportion of *gravel to lime is that of four to one*. The lime is obtained from Merstham or Dorking, and before being used is thoroughly ground to powder. The concrete is made on the surface of the road, and great care taken, when the water is added, that every particle of the lime is properly slaked and saturated. The bed of concrete having been spread to the depth of six inches over the half breadth of the road, the surface is then covered over with six inches of good hard gravel or broken stone, and this depth is laid on in two courses of three inches at a time, the first course being frequently laid on a few hours after the concrete has been placed in the road. The carriages, however, are not on any account allowed to pass over it, until the concrete has become sufficiently hard and solid to carry the traffic, without suffering the road material to sink and be pressed into the body of the concrete. On the other hand, the covering of gravel is always laid on before the concrete has become quite hard, in order to admit of a more perfect binding and junction between the two beds, than would take place if the concrete were suffered to become hard before laying on the first covering. The beneficial effect arising from the practice of laying on the gravel exactly at the proper time is, that the lower stones, pressed by their own weight and by those above them, sink partially into the concrete, and thus remain fixed in a matrix, from which they could not easily be dislodged. The lower pebbles being thus fixed, and their rolling motion consequently prevented, an immediate tendency to bind is communicated to the rest of the material—a fact which must be evident, if we consider that the state called binding, or rather that produced by the *binding*, is nothing more than the solidity arising from the complete fixing and wedging of every part of the covering, so that the pebbles no longer possess the power of moving about and rubbing against each other. It is found that, in a very few days after the first layer has been run upon, the other or top covering may be applied, and shortly afterwards the concrete and the whole

body of road material becomes perfectly solid from top to bottom. The contrast thus presented to the length of time and trouble required to effect the binding of road materials, where the whole mass is laid on loose, is alone a very strong recommendation in favour of the concrete.

The experiment of using concrete on the Brixton road, although not at present on a very extensive scale, has been tried under circumstances very far from favourable, and on a part of the road which had hitherto baffled every attempt to make it solid. Since the concrete has been laid down, however, there is not a firmer piece of road in the whole trust; and from the success of this and other trials made by Mr. Penfold, but which I have not seen, I believe it is his intention to recommend it in a general and extensive way to several trusts under whom he acts.

* * I would here however suggest, that the surveyor (or whoever may have charge of a road so constructed) ought never to admit of the covering being worn down, so as to permit the concrete to be acted upon or in any manner disturbed; but as soon as the upper surface is worn down to within two inches, or at most to within one inch of the concrete, a new covering the same thickness as before should be immediately laid on.

It may not be considered very foreign to this subject to remark, that in gentlemen's parks, gardens, and pleasure grounds, it is exceedingly difficult, if not impracticable, to make ornamental carriage roads or private walks by the old system of laying on loose gravel or broken stones; for whatever pains be taken in selecting the best kind of gravel, and afterwards in forming and rolling, worms will find their way through and destroy it by depositing a portion of adhesive earth wherever they work to the surface; and these deposits are so numerous, particularly in the autumn, and through the winter and spring of the year, that in the case of the carriage-roads, this earthy material first adheres to the rims of the wheels, and then again sticking to the gravel, tears up the whole surface to the entire destruction of the road. Garden walks from this cause frequently cannot be traversed with any pleasure—the dirt adheres to the feet, and is so exceedingly unpleasant, that such roads and walks, instead of having a hard, clean, and smooth surface, become dirty and unsightly in the extreme. I would recommend in such places, that the roads and paths should uniformly be made with a concrete bottom of only a very few inches in thickness; say three inches for carriage-roads, and two inches for paths, and with a slight covering of binding gravel on the top. This system, I think, would effectually prevent the roads from being destroyed in the manner I have described; for independent of the antipathy which the worm, and, I may add, every description of insect, entertains against lime, and notwithstanding their capabilities of boring, they never could penetrate half an inch into the concrete. As an instance of the perseverance of worms, and the mischiefs they sometimes occasion, I have myself, during a very dry hot summer, met with them in canal excavations, four feet below the surface, in hard clay; and I haveknown them penetrate afterwards out of this depth, and through three feet of clay puddle, thereby actually occasioning leakage in the canal.

The next chapter, *On the Drainage of Roads*, contains many judicious directions; and the following one, chapter VII., gives a variety of formulæ and tables for ascertaining the comparative *effects of different inclinations.*

The concluding chapter, *On the Method of Estimating the Prices of Earth-work, &c.*, will be found useful by the student, as giving various calculations and prices of labour in excavating different kinds of earth, and an example of an estimate for the formation of a road.

The History and Description of the London and Birmingham Railway. Part II. By Thomas Roscoe, assisted in the Historical Information by Peter Lecount, Esq., F.R.A.S. (Civil Engineer). London: Charles Tilt. Birmingham: Wrightson and Webb.

This second part is fully equal to the first, which we noticed in a former number (No. 10). It contains four highly-executed engravings; the first, a view from the hill above Box Moor Station towards Berkhampstead; the second, the Wolverton Viaduct; the third, Denbigh Hall Bridge, which is deserving of notice for its peculiar and elegant construction; the fourth is a beautiful view of Coventry. The letterpress possesses considerable interest. It very properly animadverts on the extortionate demands made on the company for compensation, and the disgraceful difficulties thrown in their way in obtaining the Act of Parliament.

Yes, reader, in every half-yearly report of expenditure sent forth to the twenty-five thousand proprietors, foremost in the items is recorded the appalling fact, that public-spirited men, who are willing to risk millions of their money, and lay out of part of it for seven or eight years, in order to complete such a splendid undertaking as the London and Birmingham Railway, must, before they can obtain permission to commence this work, submit to place down upon their records as the first item of their outlay—"Payments for obtaining the Act of Incorporation, 72,868*l.* 18s. 10d."

The description of the work on the line will be found particularly interesting to our professional readers: it gives a brief account of the construction and cost of the railway, commencing at the Euston Square terminus.

From Euston Square to Camden Town the railway is formed by a wide cutting or trench, about eighteen or twenty feet deep, the sides of which are composed of beautifully executed brickwork, having an iron balustrade at top, which, when the trees and shrubs of the adjoining gardens have sprung up, will form a pleasing object. The land being on a considerable rise outwards from London is worked, as before named, by endless ropes passing over pulleys in the middle of the tracks, which ropes are set in motion by the stationary steam-engines at Camden Town. Great precaution is required in attaching the carriages to the rope; and this is generally done by one man, who is trained for that purpose. The way in which he effects the fastening is by means of a small rope, called a *messenger*, having a slip knot at one end, which he passes over the rope, and holds the other in his hand as he stands on the foremost carriage, in order to release the train when it reaches Camden Town, or in case of accident. By a signal given to the engineer, the engines are stopped in an instant. The train is generally drawn up this length of railway in three or four minutes, during which time the passenger passes under several very handsome stone and iron bridges and galleries; the most extensive are those under the Hampstead Road and Park Street. The whole of this length is excavated from the London clay; and the walls which form the sides are curved, in order to resist the inward pressure; they are as much as three bricks thick at the top, and seven at the bottom; the number of bricks used in forming these gigantic walls was about sixteen millions. When the train arrives at the iron bridge which carries the line over the Regent's Canal, the carriages are detached from the rope, and allowed to run along the line till they meet the locomotive engine by which it is afterwards propelled. * *

Rapidly traversing the Grand Excavation, we soon reach the Camden Town Station, and have in view the open country, and the green and diversified hill of Highgate. In travelling thus far we have passed under seven bridges, two of considerable magnitude,—one being 484, and the other 380, feet in length. The elegant suspension bridge which is slung over the Regent's Canal cost 4,500*l.*; it is divided in the middle by one of the main girders to which the railway is suspended.

The Camden Town Depôt forms a station for the carrying department of goods, while that at Euston Square is set apart for passengers. The former contains thirty-three acres of land, which are raised several feet above the regular surface of the ground, and supported by a wall; so that heavy goods may be easily lowered from the railway waggons into carts, to be conveyed to their destination. At this station is a very extensive locomotive engine-house, which cost 21,000*l.*; several ovens for making coke for the use of the engines; a repository for cattle brought by the railway to supply the London market; stabling for fifty horses; a manufactory for carriages; and offices for a large establishment of clerks, and of the engineer in chief and the resident engineer. Here, also, are the stationary engines for working the ropes, but they are under ground, immediately below the railway; their situation is marked by two very elegant chimneys, which belong to the boilers; these rise to an height of 133 feet above the rails, and are twelve feet diameter at bottom and six at the top.

The ingenious contrivance adopted for communicating from the terminus at Euston Square with the engine-house at Camden Town, a distance of about a mile, is deserving of notice. We believe the first telegraph of this description, if it may be so called, was introduced at the tunnel on the Liverpool and Manchester Railway.

In the engine-house is an organ-pipe or whistle, which communicates with the passenger station at Euston Square by a tube, along which a signal can be conveyed to the engineer in four seconds. The way in which the signal is now given to start the engines, is by an apparatus similar to a gasometer; it consists of a weighted cylinder, which dips into another cylinder filled with water. On allowing the upper or inner cylinder to descend, the air which it contains is forced down an upright pipe in the inside of it, and passes along a pipe under ground; then, as it rushes out at its other end through the whistle, the signal is given to start the engines.

The Book of the Grand Junction Railway. Part 2. By Thomas Roscoe, Esq., assisted by the resident Engineers of the Line. London: Orr and Co.

This work may be considered as forming a continuation of "The History and Description of the London and Birmingham Railway;" it is got up with the same good taste and judgment. The present number is far better than the first, and possesses much more interesting information connected with the railway; it briefly describes the construction of the works, and such objects on the line as may be worthy of notice by the traveller.

A Dictionary of the Ancient Architecture of Great Britain. By John Britton, F.S.A. In one large volume, royal 8vo. London: Longman and Co. 1838.

The name of John Britton has been for so many years honourably associated with architecture, and his contributions to its literature have been so much more extensive than those of any other man, that the profession looks to any work that he may issue with more than ordinary attention and respect. This has, of course, been the case with the Dictionary before us, which was issued in parts, and has been for some time in the hands of the public, the first part having been published in 1830. In such a

length of time the public have had it in their power to form their own judgment, and our task is necessarily restricted.

Compilation in any department of literature or science requires the greatest care and discrimination, and in the formation of a Dictionary more, perhaps, than in any other branch. When such a work is connected with an art or science, abounding with technical terms, derived from classic or foreign languages, it imposes a greater responsibility on the author; particularly in architecture, where there are few defined standards, but many individual masters employing their own forms of expression. The writer who undertakes such a work must enter into deep researches, examine every architectural author, and trace out every existing word which is not common to the English language, while considerable judgment is necessarily required to ascertain what is necessary from that which is superfluous. We need not wonder if, in Mr. Britton's case, this has required some time; and the public will see that he has, to the best of his ability, fulfilled the task.

There are many omissions which occur to us, such as the terms *arcs doubleaux, bird's beak moulding, fan-groining, hipped roof, raking cornice, stump tracery, terracotta,* &c. The first term is indispensable, as we have no English word equivalent to it, and it is adopted by all our writers to express one of the peculiarities of the Italian style. Among the foreign synonymes some startling errors have crept in, which on a future occasion may be avoided; as *rechentisch*, given as the German for abacus; *pilaster*, from *pila*, Latin; and *astro*, Italian, indicating an inferiority! Such defects are, unfortunately, not uncommon among dictionary makers, and the patriarch lexicographer himself was not exempt. In the first edition of Johnson's Dictionary, cotton, mahogany, and a number of terms are not to be found, while there is abundance of most cacophonious Latin barbarisms. Not to mention perversions of meaning, among other pieces of learned ignorance the doctor informs his readers that *mainsheet*, instead of signifying a rope, means the great sail of a ship.

The Dictionary contains some useful information, and so far the profession is indebted to Mr. Britton for his additional labours on a subject to which he had already contributed so much. The nature of the work necessarily involved much archæological research, and the author has, perhaps, done wisely in catering for the antiquarian as well as the architectural student. The plates, exhibiting specimens of various details of the different ancient styles, are engraved with considerable care and beauty, and no exertion as to expense seems to have been spared to render the work worthy of the public.

Mr. Britton returns to his old favourite subject of denominating the mediæval styles Christian architecture, although we may observe, by-the-by, that the term of Gothic is not so inappropriate, the northern invaders of Europe being all derived from a Gothic stock. Some of his engravings present beautiful arrangements of foliage not to be excelled by any school, and fully redeeming the taste and genius of the middle ages.

We should very much like to see a more complete general Dictionary of Architecture and Engineering, undertaken by two or three persons jointly, the Gothic, Grecian, and Roman forming, perhaps, separate departments, and the engineering portion being executed by some one more especially versed in that branch, and acquainted with its technical terms. Such a work is much wanted, and we have no doubt that, if undertaken with spirit, it would well repay the authors for their trouble.

A Practical Treatise on the Construction of Stoves, and other Horticultural Buildings, and on the Principles of Heat as applied to Hothouses, Conservatories, and other Horticultural Erections. By J. W. Thompson, Nurseryman, &c. 8vo., with Wood Engravings. London: Groombridge.

We feel always gratified when we receive any contribution to architecture from the departments accessory to it, as it is by such subdivision of labour that the science must benefit. This work is by a practical man, and being upon a subject with which he has been long intimate, it may naturally be believed that it possesses considerable interest. In it Mr. Thompson points out the advantages of wood over cast iron for horticultural purposes, and then considers the points necessary for the construction of a conservatory; he gives a variety of designs, among which is one by Sir Charles Cockerell, erected at the Grange, in Hampshire, for Lord Ashburton, which possesses considerable novelty and elegance, and is a marked deviation from the old and common place designs.

With regard to some observations in this work, in which Mr. Thompson seems to deprecate the employment of architects, and wishes to make them the tools of gardeners, we should remind him that such a course would prove particularly disadvantageous to the interests he advocates. Independently of the consideration that floriculture is just as much a matter of taste, and as little a matter of money-making, as any other kind of ornament, we certainly think that to a nobleman a great attraction of a conservatory is derived from its architectural effect; for we do not imagine that for the mere contemplation of fruit or flowers any man of taste would load his grounds with barrack-like greenhouses of a nurseryman's garden. In the instance which we have given we think that much of the merit of the conservatory is owing to the taste displayed by Sir Charles Cockerell, and which without the advantages of colour produces a most picturesque effect. We think the noblest property of flowers is that exquisite lesson of divine beauty which they inculcate, and we should prefer the moral effects of such a display to all the pride of a victorious apricot or a prize dahlia. It is very natural however that Mr. Thompson should have a preference for leather, and we are sure that he will excuse us in vindicating the connexion of his own with the other liberal arts.

In the subsequent part of his work Mr. Thompson describes his egg-shaped boilers, to which it is unnecessary for us to refer, as we are previously indebted to him for his communication on this subject in one of our former numbers.

This work is highly useful and interesting, and acquires additional claims to attention, at a period when botanic gardens are making such progress in all parts of this country; and as Mr. Thompson remarks, it cannot fail to be necessary to architects engaged in such works to make themselves acquainted with the practical details of their construction.

ORIGINAL PAPERS, COMMUNICATIONS, &c.

RALPH REDIVIVUS, No. 10.

THE ADELPHI.

That this range of houses would have a profusion of the most laudatory epithets bestowed upon it, were it ever to find its way into one of George Robins's advertisements, may be taken for granted as a matter of course; but that it should ever have been seriously styled "a most magnificent pile of building," is almost incredible. At the same time, its having been so characterized furnishes a proof that words are sometimes put together without the slightest meaning. Magnificence may be defined to be grandeur accompanied with sumptuousness or richness, which latter, be it observed, are not essential to grandeur, for an edifice may be grand from its magnitude and relative proportions, although of decoration it may possess very little.

The Adelphi, however, possesses merely largeness, unaccompanied by magnitude of forms and proportions, and is equally devoid of richness. It is true there is some embellishment, or what is intended to be such, applied to it, yet with so little feeling, or even skill, as to occasion only an offensive disparity between the ornament and the thing attempted to be ornamented. Leaving alone for the present the taste of the decoration itself, it is evidently misapplied, because bestowed on what, so far from being at all adapted to receive it, is homely even to bareness and baldness. We behold a range of common-sized houses, whose windows are mere holes in the walls, and which have nothing whatever to distinguish them from those in nearly all the streets at the west end of the town, save that the two centre houses, and that at each end, have pilasters stuck up against them, for the purpose of giving to the whole range the appearance of a single continuous façade. At the same time everything contradicts such idea, and counteracts such impression: the numerous small doors, squeezed-up areas, crowded windows, all hinder us from fancying for more than a moment that we behold a single large structure—one neither divided into separate dwellings nor cut up into small rooms. The same remark applies to the so-called '*Terraces*' in the Regent's Park, and those on the Bayswater Road, some of which would be far more appropriately characterized by the name of barracks, to which latter, though not intended to do so, they bear a much stronger resemblance than to palaces. At the best they look like no more than one side of a street of tall houses, turned out for an airing; for they are stretched out so indefinitely that, as masses of building, they are less imposing in their general aspect than the Adelphi, which Cumberland has styled—

> ———"The fraternal pile on Thames' banks
> That draws its title, not its taste from Greece."

Robert Adam was certainly a man of some talent, and modern domestic architecture is indebted to him for not a few improvements which he introduced; but, unfortunately, he was not gifted with the most refined or delicate taste; not but that there are many exceed-

ingly tasteful ideas to be met with in his designs, but then they seldom occur except as mere random hits; even the best of his works presenting many gross blemishes mixed up with its beauties. He seems never to have bestowed any revision on his designs, but to have adopted them at once, for better and worse, with all their imperfections on their head. If he was in many respects an architectural fop, he certainly was also an architectural sloven; and of both his foppery and slovenliness in architecture, the building here noticed affords incontestible proof. Its embellishment is so finical as to appear ridiculously outrè—almost intended as a satirical caricature. It is a barrack tricked out and dressed up after the fashion of a boudoir; the consequence of which is, that, affecting to be eminently fine and refined in style, it is eminently vulgar, rendered paltry by mal-à-propos embellishment.

Wherever windows predominate, as they certainly do here, the first study of the architect should be to render them expressive in the design, and either to adopt or to adapt his style accordingly. Instead of which, Adam thought he might as well spare himself that over-refinement of thought and trouble, by making his windows mere holes in the wall, and patching on some *genteel* decoration beween them, so that no one should say either that economy had not been consulted, or that taste was altogether omitted. And it must be admitted that the taste here displayed was peregrine enough. Another would probably have contented himself with merely adding plain pilasters and entablature to his row of houses, whereas Adam seems to have fancied that would be making homeliness more homely: his taste scorned the idea of common slices of pilaster. He accordingly determined to astonish the public by a specimen of the richness of his ideas in decoration, panelling his pilasters and filling them up with a showy pattern, which he took care to extend likewise to his entablature, making amends for such extravagance by omitting the architrave, and reducing the cornice to little more than a moderate sized moulding. The town was in ecstasies of astonishment: it shouted out superb! magnificent! and now, alas! nobody thinks it worth while to turn down from the Strand even to take a peep at Adam's magnificent pile; or if any one does, he returns filled with astonishment of a very different kind—surprise that such a paltry gingerbread piece of architecture should ever have been admired, for now-a-days many of the gin-palaces about town exhibit quite as much grandeur, and far more consistency of design.

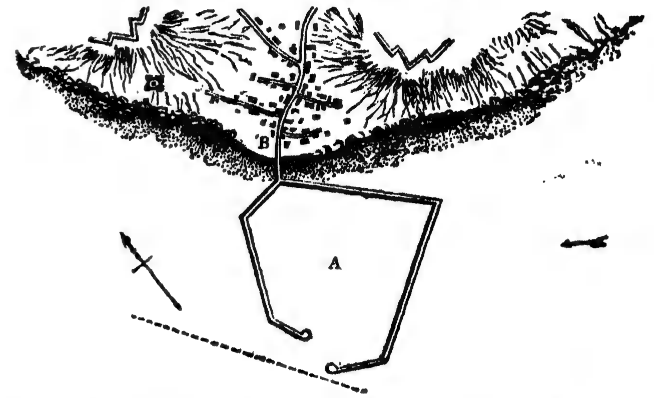
After all, in spite of the Adelphi, and some other flagrant enormities, Robert Adam was, as I have said, a man of some ability and cleverness, but exceedingly unequal, often very happy, in particular parts, and very seldom indeed, if ever, satisfactory upon the whole. So far from being at all scrupulous as to innovation, he was ambitious of striking out a new style; but he mistook the reverse of one error for a distinct merit; whence, in endeavouring to emancipate himself from the formal heaviness of his predecessors, he fell into a meagre flimsiness and flutter, and was apt to bestow a great deal of finical ornament upon buildings which were architecturally of the utmost plainness: consequently there generally prevails a marked antipathy between the embellishment and the thing it is applied to, which suit with each other about as well as a Quaker's prim drab bonnet, and Parisian artificial flowers.

Neither is this false taste entirely to be ascribed to his studies of Diocletian's Palace at Spalatro, for impure as both the composition and details of many of its parts were, in many there was rather an excess than any deficiency of architectural details, elaborately wrought entablatures and doorcases, indicating a totally different gusto from that which led the architect of the Adelphi to put a narrow horizontal stripe upon his pilasters, to leave his windows mere holes in the wall, and to make his doors hardly less insignificant. Even much of his ornament is itself in very bad architectural taste, and seems to have been derived from the patterns of paper-hangings, it frequently consisting of sprigs and leaves looped up with shreds of ribbons; so that instead of being rich, it looks hard and dry. The panels of the pilasters of the Adelphi have the appearance of having been stamped with a butter print.

For grandeur or beauty Adam had no soul: nearly everything he did bore the mark of littleness and pettiness, frequently of prettiness also; therefore, where prettiness alone was required he succeeded. He was, withal, a great mannerist: like the Adelphi, the house at Kenwood is quite in the *twelfth-cake style*—patched all over with panels of filagree work, so that one might be excused for imagining that it had been erected by some retired pastry-cook, in order to enjoy his *ocean-full of dignity*—as a late worthy Baronet ventured to translate the words *otium cum dignitate*.

At the rate I am going on it will be said that I shall pluck Robert Adam's reputation absolutely bare, nor leave him even a single feather of any kind; passing over, therefore, all the manifold architectural vices and sins with which he is justly chargeable, I freely own that in some cases they are counterbalanced by the excellence of his plans. His forte lay in interior arrangement, and in both the distribution and the forms of rooms. Herein, as in some other respects, he was the Soane of his day. The large circular saloon designed for Sion House is strikingly beautiful in plan, fraught with piquant complexity, yet without confusion. Had he, therefore, done nothing meritorious, except breaking through the monotonous system of making houses only nests of square boxes, we could almost forgive such a mawkish piece of architecture as the Adelphi.

HARBOURS OF REFUGE.



Plan of WILLIAM TAIT, ESQ., C.E., *for forming Isolated Harbours.*

Harbour engineering is of all departments that which is more particularly in a barbarous state; there is no acquaintance with general laws, and an especial deficiency of local information. There is hardly one harbour among the many constructed in this country, which has been formed by an attention to fundamental principles; but the moment an engineer is appointed to form a plan for such an undertaking, he goes to work at second hand, and without any regard to locality, endeavours, *mutatis mutandis*, to apply some construction which has been successful in another place. Smeaton has backwater at Ramsgate, and, therefore, other situations must have it also; and there is a pier in a hundred places, and so it would not do to be without that. The consequence is, that where there is a bar it is made worse, and if there be none, one is very soon formed. Meanwhile the unlucky engineer is confounded with his ill-success, and knows not to what to attribute it; he has a better pier than his predecessor, and has made important improvements in the hinges of the lock-gates, while the only end of his vexations is, that the harbour is choked by a south-wester, and the pier goes to the devil in a storm.

While we are making gigantic efforts with regard to canals, docks, and roads (and the progress of the country is perpetually requiring new ports), there is scarcely one of our harbours that has been doctered which is not injured. The effect is most prejudicial to our commercial marine, for it operates on many most important places; in fact, we need only refer to Dover, Yarmouth, Whitehaven, Dublin, and many others, where our best engineers have been baffled, and all their operations disconcerted. This has in most cases been caused by a want of attention to physical laws; but it may likewise have some influence, that in such works, a degree of nautical knowledge is required in the details, which is too often neglected by the engineer.

The evil has become so apparent, that it has excited considerable attention and discussion, which is the true way to elicit the truth. One of the oldest dogmas of harbour engineering is the necessity and utility of backwater, and there is none more fallacious; it is the attempt to obtain this which has caused more errors, and wasted more money, than all the other sources of ignorance put together. The Thames, the Severn, the Shannon, and the Humber, have backwater, and, therefore, engineers have run mad to follow the example. Although a large body of water might force a passage, that is no reason, but the contrary, why a small quantity should be effective. You might put a fire out by a pailful, but it consumes the water if only dropped upon it. Neither is it absolutely true that a great body of water will force a passage, not to mention the Rhine, or the Nile, the Tagus, the Douro, and many other rivers, which are barred by superior force. This absurd doctrine was not doubted, we believe, until lately, as it has been acted upon from Smeaton down to Dover Harbour, until it was combated by Mr. Henry Barrett, in his plan for Lowestoft Harbour, brought before Parliament last year. He affirmed that the cause of bars was, that the stream of backwater fell

upon the tidal current at right angles, and that the bar was formed by deposition at the place of meeting of the matter held in solution. His remedy was that the stream of backwater should be brought into union with the tidal current at as small an angle as possible, so that the united stream might carry off the silt. This principle is of general application to all similar cases, and shows that the farther you carry out your backwater at a wrong angle, the farther you extend your bar.

A principle adopted by Mr. Hyde Clarke is that of clearing out a harbour by bringing the tidal current in to act upon it, instead of relying upon backwater. A survey for a plan of this kind is now being carried on at Dublin, by Mr. F. W. Beaumont, for insulating Howth Head, and clearing away the North Bull Sand.

In Mr. Rooke's work, reviewed in our present number, these theories are confirmed, and a great deal of space is devoted to the consideration of Tynemouth, Whitehaven, Maryport, and many other harbours.

One great difficulty in the way of most harbour designers is the stream of shifting shingle flowing along most of our coast, and ever ready to choke the shingle traps of the fated engineers. Upon this devastating enemy they have exhausted their sluice gates and backwaters for years, and they would doubtless feel happy to ascertain any means of disposing of their antagonist. We feel no less gratified on our part to see any effort made which may introduce something new into the annals of science, and rescue engineering from the routine of piracy and second-hand robbery now too prevalent, and degrading to a profession which ought to be one of genius.

We have been favoured by Mr. Tait with a plan and description for the formation of harbours, which we consider well deserving the attention of our professional readers, both for its originality and ingenuity. In his remarks accompanying the plan he more immediately applies his observations to the Kentish coast, upon which and upon every part of Kent his professional labours give his opinion much weight. These remarks, however, are susceptible of an application much more general. He, in the first place, expresses his complete disapproval of the scouring power, in which, from our remarks on Lieut. Worthington's work on Dover Harbour, he will find that we entirely coincide. After giving Mr. H. R. Palmer's observations on shingle, he proceeds to explain his own plan, although justly remarking that it would be improper to give any specific plan, without first seeing the spot at which it was intended to construct a harbour on any principle. He observes, that when the shingle in its transition has to pass through a narrow gorge, it continues to be borne along and to travel onward, by which case nature herself has pointed out a principle, upon which the shingle may be assisted to pass forward, and its accumulation in any particular spot prevented. The object being, therefore, not to obstruct the shingle in its progress, Mr. Tait suggests an *isolated* harbour; that is, that the harbour shall be built independently of the coast, and united to it by a bridge, under which the shingle may pass; and the mouth of the harbour being in sufficiently deep water, no cause will exist to diminish the depth of water, impede the silt, or stop it up. This is in full support of what we had advanced with regard to Dover Harbour; "whatever is done, no attempt must be made to oppose the progress of the shingle, for that is, in our opinion, impossible."

Mr. Tait remarks, that any extra expense which might be incurred by the nature of such a work, would be more than compensated by its advantages; while its application would render the construction of harbours a matter of facility in any position, however difficult it may hitherto have been considered.

Annexed is an imaginary plan, showing the construction of an isolated harbour on Mr. Tait's principle. A, is the harbour, which is connected with the land by a bridge; B, revetment or sea wall; the arrow indicates the tidal current, and the dotted line the course of the prevailing south-west wind.

ON THE LATEST MEASUREMENTS OF THE PARTHENON.

TRANSLATED FROM THE GERMAN COMMUNICATION OF JOSEPH HOFFER, GOVERNMENT ARCHITECT AT ATHENS, IN THE "ALGEMEINE BAUZEITUNG" OF VIENNA.

The labours of Stuart, Revett, and others, having thrown so much light on the architecture of Athens, it occurred to some residents to go over the works there, and ascertain the correctness of the details given by these authors. This was undertaken by Mr. Hoffer and two of his colleagues, and the results have not been without interest. These investigations have elicited that the Greeks paid the greatest attention to produce perspective effect, even in the minutest details; and that their edifices are by no means so simple in their construction as the measurements hitherto given have caused to be believed.

The measurements were conducted with the greatest care, and by the best instruments that could be made in Bavaria. The first operations were begun in the Parthenon, to ascertain the proportion of the entasis or swelling of the shafts. As they could place no dependence on the plummet, an iron cramp was fastened on the shoulder of the capital, and another on the lowest tambour of the column; between each cramp a silk thread was stretched tightly, and brought so close to the column as to touch the entasis, by which it was seen that the thread stood at an equal distance from the column above and below. By this examination they found that the position of the highest point of the swelling varied in every column. The average of several measurements gave about 5-12ths of the whole length of the column, reckoned from below as the situation of this point.

Besides this they remarked, that the several columns in the direction of the length and breadth of the temple, did not stand perpendicularly to their axes, but that they had an inclination from the middle ones outwards, sideways, and diminishing from the corner columns towards the centre. The reason for this inclination will be communicated subsequently.

By the measurement of the entablature it was farther shown that all lines which have hitherto been received as straight and perpendicular, were not so throughout, but appeared to have been formed with a flat curve towards their versed sine, so that the architrave appears to have sunk on both sides. At first it was conjectured that this might have been caused by some disturbance, but subsequent examination showed that all the constructive lines, from the lowest step to the cyma, followed this curve, and that all the vertical joints were in such perfect preservation that the stones seemed almost melted together. The south and north sides of the temple were found conformable to the eastern, which was the first examined. In order still farther to confirm these observations, the Temple of Theseus was similarly examined, and the same circumstances ascertained, and that the inclination from the right line in both cases was in relation to the size of the temple. The rise or versed sine of the curve is about $1\frac{1}{2}$ to 2 inches in the centre of the length of the portico. It seems probable that in this circumstance we may find some clue to the enigma of Vitruvius respecting *Scamillis imparibus*.

Besides this curve of perpendicular lines from above, which to distinguish from the others we shall call convexity, these perpendicular lines have a second curve, namely, inwards towards the temple; the length of the sine is about $1\frac{1}{2}$ inches. This class of lines, like the preceding, are all parallel to each other, and have the same curve. If this curve should also be found in the Temple of Theseus, it will prove how elaborate was the attention devoted by the Greeks to architectural effect.

To return to the inclination of the axes of the columns of which we have already spoken, it seems to clear up an obscure passage of Vitruvius, in which he says, "Only the middle columns are perpendicular, the others being inclined towards the temple." The case occurs exactly here where, on the long side of the temple, there is a great range of columns, only the central ones being perpendicular, the remaining inclining to the corners. On the short sides, where there are less columns, none are perpendicular, but all incline themselves towards the corners. The measurements of a great many columns have been taken for this purpose, and they all agree, and at a future period the Temple of Theseus will be examined for the same object.

With regard to the construction by which these abnormities, if we may so term them, are produced, it appears that these bendings are by no means produced by perfect curves, but that the lines are polygonal, and that each block of an architrave or a step is rectilinear in itself, the effect being produced in the arrangement of the joints. The inclination of the columns is effected by giving an inclination to the upper surface of each tambour, which is continued through every piece.

The walls and antæ of the cella seem to exhibit similar inclinations.

The continuation of the investigations on this subject will serve to throw a clearer light on the case, and enable us to decide how far importance ought to be attached to the previous observations.

ANALYSIS OF SAND STONE.

ON THE CORRECT METHOD OF ASCERTAINING THE RESISTIBILITY OF STONE TO FROST, TRANSLATED FROM THE GERMAN OF DR. BUEHNER, PROFESSOR IN THE UNIVERSITY OF VIENNA.

The means of ascertaining the capability of resistance of stone against frost occupied the attention of scientific men at an early period; but, although some recent communications have been made on the subject, they are but reproductions of the experiments of the mineralogist Brard. His system, which is that of subjecting stone to the action of Glauber salt, so as to produce a low temperature, has long been adopted as a universal medium in most countries of Europe, and sanctioned by many high authorities. It is truly observed, however, by Professor Fuchs, in Erdmann's Journal, that such a mechanical method is of no more certainty than to rasp the stone with the finger nail, or strike it with a hammer, and that the only competent test is to subject it to chemical analysis.

The builders employed on the royal works at Munich have, in the course of their extensive practice, resorted to this process of analysis in preference to the usual method, and the following is an account of the experiments of M. Stumb, principal builder in that city:—

On the occasion of repairing the weather side of the tower of the Lady Church, at Munich, he instituted an examination into the sandstone of Waakirchen, in the district of Wiesbach. This sandstone is of a bluish grey colour, equal and fine grain, noways splintery, of moderate hardness, and giving sparks when struck with steel. On a closer inspection, minute specks of mica and quartz may be perceived.

A piece of this stone, weighing 80½ ounces, was laid in distilled water for

24 hours, and on being taken out and weighed, it was found to have increased 6 grains, hardly two per cent, and affording a good proof of its closeness of formation, and small power of absorption.

The water in which the stone had been laid was evaporated to an ounce, and a yellowish residuum obtained, which, on being subjected to reagents, was found to consist of sulphate of lime and sulphate of soda, mixed with organic matter.

A piece of the sandstone was pulverised, and 100 grains of it treated with muriatic acid, and a partial dissolution effected by the development of carbonic acid gas. The remaining acid having been renewed by evaporation, the residuum of quartz sand was washed and cleaned with warm water, and found to weigh 57 grains.

The muriatic residuum was subjected to nitrate of ammonia, whereby alumina was produced, with a portion of oxide of iron. It weighed, on careful trial, 3½ grains.

The solution filtered from the aluminous precipitate was treated with oxalic ammonia to produce deposition of the lime, which was exposed to the fire to convert the oxalate of lime into carbonic acid gas, and by which 24 grains of carbonate of lime was produced. The fluid filtered from this was acted upon by phosphate of natron, and a precipitate of phosphate of ammonia and magnesia appeared, which by heat was reduced to neutral phosphate of magnesia, which was calculated as 13 per cent. of carbonate of magnesia.

The composition of the stone was, consequently,

Quartz	57
Alumina	3·5
Carbonate of lime	24
Carbonate of magnesia	13
Loss	2·5
	100

From these results it was proved that the sandstone of Waakirchen was a good building material, and fully capable of resisting the effects of air and water, as its component parts were not liable to decomposition, and its texture did not admit the introduction of their mechanical force.

It is evident that it is only by such trials that the true qualities of materials are to be ascertained, as mere mechanical action, or a trial of temperature, affords no criterion of the chemical constitution by which injuries of weather are caused.

ZANTH'S DRAWINGS.

Some architectural drawings were exhibited at the rooms of the Institute of British Architects, on Monday, the 17th ultimo, which although very limited indeed as to number, must have afforded very high gratification to those who beheld them, being of superlative interest as to subjects, and of superlative excellence as to execution. We have seen many able and carefully executed drawings of this kind, that have charmed us by their accuracy and their taste; we have seen many also that have captivated us, by their masterly effect and bravura, by their breadth and play of light and shade;—in fact, we thought we had seen the ne plus ultra of water-colour painting as applied to architectural subjects. Accordingly we went with the expectation of beholding some good subjects respectably treated. Great then was our astonishment, greater our delight, when after looking at some of the smaller drawings on the table, that seemed to corroborate our preconceptions, we turned to the interior of the church of the Convent Olivella, at Palermo. It is a perfect gem—a chef d'œuvre of the most finished beauty, finished up in every part most surprisingly, elaborated with diligence incredible, yet in such a manner as to produce a magical effect of nature; a most powerful and brilliant yet clear and quiet effect, combined with extraordinary vigour and depth of colour, yet at the same time entirely free from all exaggeration, and from all those conventional artifices of shadowing which are almost invariably resorted to; for all the parts and figures in *demi-jour* are in perfect daylight, though quite in shadow compared with the rest. This is the case with the whole of the foreground, and yet the priests in their magnificent robes, the carved stalls, the statues, the superb mosaic pavement—every object and all its details are expressed with a verity truly astonishing. The local colouring is preserved in all its nuances, so that when you examine any one part, it appears a finished picture in itself; and yet with regard to the rest it does not appear at all obtrusive, the keeping of the whole composition being truly admirable. To say nothing of the skill shown in it, the labour alone demanded by such a subject must have been quite formidable; for there is an infinitude of detail, and the utmost variety of material, variegated marbles, bronze, gilding, frescos, inlaid pavements, &c.; nevertheless, as if all this exuberance and prodigality of forms and colours did not afford exercise enough for his pencil in one drawing, M. Zanth has introduced numerous figures in the foreground, so admirably touched, that Turner's dots, specks, and blotches, crossed our imagination at the moment, and we blushed for English art. Nay, we question whether, if placed by the side of this fascinating drawing, the very best subjects of the same class, by any of our English water-colourists, would not appear either very tame and spiritless, or else exceedingly rough and sketchy, not to say slobbered.

Besides the above there were two other interiors of the same size, viz., that of the Cathedral at Monreale, and of the Chapel Royal, Palermo; two splendid architectural scenes, arrayed in all the pomp of gold and mosaics in the roof and upper part of the walls. For description we have no room, nor will we bore and tantalize the reader by our ecstasies, and therefore throw down our pen at once, after saying that though we wish no harm to M. Zanth, we do hope that he will not be permitted to carry back those three drawings with him out of this country.

NEW SYNAGOGUE, GREAT ST. HELEN'S.

This building, erected from the designs of Mr. J. Davies, which is approached through a passage at the rear of Crosby Square, was consecrated on the 14th ultimo. The exterior has not very much the appearance of belonging to a place of worship, for it consists of a small loggia, formed by three open arches resting upon coupled columns, with an upper floor above it, having five arched windows, the end ones being over those which occupy the parts below that enclose the loggia. The centre portion, which is crowned by a bold block cornice, advances a little before the rest of the front, which has plainer windows, and a door in each of the compartments so formed. Within the loggia are three doors, that open into a narrow vestibule or corridor, running transversely to the body of the building, at the end of which are staircases leading to the galleries for females, and to the committee-room, occupying the upper floor of the centre of the front. Facing the doors from the loggia are others which open immediately into the interior of the synagogue. The effect, on first entering, is very striking, owing not only to the splendour of the sanctuary at the other end, but also the spaciousness, lightness, and elegance of the ensemble; for instead of the floor being occupied with pewing, which in all our churches encumbers the lower part, and gives it a mean and huddled up appearance, the sittings below hardly extend beyond the pillars that support the galleries, and instead of being enclosed have merely a dwarf parapet before them. The reading-desk, or whatever may be its peculiar name, is a spacious platform enclosed by a low parapet, upon whose pedestals stand massive candelabra of gilt metal. There are similar ornaments within the sanctuary; besides which, gilt lamps are suspended from the fronts of the galleries. These have an upper order of Corinthian columns, making five intercolumns on each side; corresponding with which are as many windows of ground glass; and one peculiarity belonging to these windows is, that they have dressings and cornices, which certainly gives a very great degree of architectural finish to the design. In other respects, however, there is little decoration, if we except the gilded metal foliage and scrolls, intended to serve the purpose of *grilles;* for, though forming apparently an open-work parapet to the galleries, they are raised upon the real parapet, which is the Doric entablature of the lower order. Here every part of the architecture itself is of a uniform white tint, the display of colours being reserved entirely for the sanctuary or ark, a spacious semicircular recess, adorned with two orders—the lower a Doric, in pilasters painted in imitation of verde antique, on a porphyry ground; the upper Corinthian, in pillars and pilasters, in imitation of Sienna marble, with three windows in the intercolumns, of a rich arabesque pattern, in stained glass. The ceiling is a semidome with octagonal coffers, containing gilded flowers on an azure ground: and the pavement, which is of polished marble, forms an entire circle, one half of it projecting so as to form two steps leading up to the sanctuary. In addition to this richness of colours, there is much decoration in the way of gilding, both on the entablatures and the capitals of the columns; the latter, however, are not gilt *en masse*, but merely tipped with gold on the mouldings and foliage. Had some gilding and colouring been extended, although in a very subdued degree, to the windows and other parts of the side elevations, the general effect would, in our opinion, have been much improved. The dimensions of the interior are 72 feet by 54, or 32 between the galleries, and 45 high.

ON THE CONSTRUCTION OF SKEW ARCHES.

Sir,—Having read the article on the construction of skew arches, in which C. L. O. has attempted to lay down the most simple method of setting out arches of that description, and to point out the errors into which he conceives Mr. Fox has fallen in his essay on that subject—both which he has most decidedly failed to do—I should feel obliged if you would allow the following remarks to occupy a portion of your valuable journal, hoping that C. L. O. may be induced thereby to reconsider his remarks, and correct the errors that a tyro has taken the liberty to point out, and finally succeed in "rendering the subject of sufficient simplicity to suit the most ordinary capacity."

He commences with such a misconception of the essay in question, that one can scarcely believe he has ever read it with attention. He says, "Mr. Fox states, in the first place, that a skew arch is really a square threaded screw wound round a cylinder, and with this position in view he proceeds to explain the mode of constructing the arch, all of which is unfortunately wrong." Mr. Fox no where says that it is, nor anything like it; he has evidently had too much practical experience, and is too good a geometrician to commit such a blunder. C. L. O. is unfortunately wrong in making such a statement. Mr. F. does not commence his essay with a lengthened definition of a skew arch,—whether it is formed by winding a straight or a spiral line round a cylinder,—whether the section be waved always at right angles to the axis, and the angle formed by the thread itself continually changing as it recedes from the centre,—or whether the face be level at right angles to the axis only at the key stone, and always forming the same angle with the axis of the cylinder when viewed from above; but proceeds at once to show the most "simple mode of setting out and working the *courses* of stones in a skew arch, so as to bring in the thrust in a proper direction;" and it is a course of these stones, not the arch itself, that he speaks of as being in the form of a "spiral quadrilateral solid wrapped round a cylinder, or, in plainer language,

the principal of a square threaded screw;" a fact that half an hour's study will discover to any one.

But C. L. O. having committed one error, necessarily falls into another (for it is evident that he has all the way considered Mr. Fox to be speaking of the face of the arch, when he has been speaking of the beds of the courses); he says, after having referred to his diagrams, &c.—"from this statement it will be apparent that the intermediate development of which Mr. Fox speaks is quite unnecessary," &c. If he will examine his model, for it is presumed he has one, or recollect what he has said in reference to the thread of a screw, "that the angle which the thread itself forms with the axis is continually changing as the parts of the thread becomes more remote from the centre," or turn to Mr. Fox's diagrams, he will immediately see that the joints of the beds *cannot* be at right angles to the approximate line both at the extrados and intrados; hence the value and importance of the intermediate development, that the arch may exert all its force in a true direction.

He next proceeds to remark on the problem Mr. Fox has introduced for ascertaining the twist of the beds, which he says, however simple it may appear to himself, is not certainly very intelligible to a working mason. If the operation is not so easily comprehended as could be desired, it unquestionably produces a correct result, which it strikes the writer cannot be obtained by C. L. O.'s method, thus described (page 280):—"Let figure 4 represent the front of a skew arch, the front of the key stone, the dotted soffit of which is shown at D, figure 3, is here indicated by the shaded surface, and the back of the same stone is shown by the dotted outline beside it. The distance from P to G, figure 4, is the difference between the distance of the front and back of the stones from the centre, or highest part of the arch. If two lines be drawn through these points, as nearly as possible at right angles to the curvature of the arch, the angle formed by their intersection will be the actual wind of the stones."

Now it is obvious, that if the soffit be equally divided, and all the stones on the face of the arch drawn as nearly as possible at right angles to the curvature of the arch as he directs, that the stones at the base, having a centre (as he tells in page 313) higher up the arch, must be thicker at the extrados, or back, than those at the crown, where that part of the curve is described by a longer radius, and approaches nearer to a straight line than that part of the curve at the base (described by a shorter radius); and any one can see that the nearer the curve approaches to a straight line, the more distant from that line will be the point of intersection, and the nearer will the sides of the stone approach to parallelism; consequently the angle of the twist (obtained as directed) will vary in every course, and the operation must be repeated accordingly, and the "working mason," instead of having to solve one problem, will probably have to work a hundred; indeed this method appears to me to involve an insurmountable difficulty, because the angle of the twist must be continually changing in each individual course as it proceeds from the base on one side, or face of the arch, across towards the crown on the opposite side.

It seems not a little strange, after having corrected the error (page 313) which C. L. O. says he committed in consequence of having inadvertently followed Mr. Fox's essay, that he should so strongly recommend Mr. Fox's method of working the stones by the straight edges and square, which is founded on the very principal that he explodes, viz., that the centre of the cylinder is the axis of the arch, and that all the beds must point to it as Mr. Fox's description of the square and mode of application will prove, one limb of which he says shall be made to the curvature of the soffit, and the other the *radius* of this curve, always taking care that this square is kept at *right angles to the axis*.

Having thrown together these few unscientific, and I almost fear in some points unintelligible remarks, simply for the purpose of eliciting a fuller explanation of those parts which present to my mind so many difficulties, I beg only to observe further, that I have never studied the subject before, or read Mr. Fox's valuable essay (vol. 3, page 251, Architectural Magazine), but that I perfectly comprehend the rules he has laid down, and believe that he has pointed out every thing requisite to enable any one to construct the arch in question without difficulty. If a more simple method *can* be devised, it would certainly be valuable. I hope C. L. O. may be disposed to persevere in the attempt, and ultimately succeed in rendering his rules suitable to the ordinary capacity of A STUDENT.

"ROMAN CEMENT."

REPLY TO H. N.'S OBSERVATIONS.

Sir,—As your correspondent, H. N., charges me with great incorrectness in my remarks upon cement, I may perhaps be allowed to say a few words in vindication of my statements.

That a very great increase has taken place during the last few years in the consumption of Roman cement may easily be accounted for, by the immense increase in building all over the kingdom; but that several other substances have been introduced to the public notice,—many of which have partially superseded the use of Roman cement,—is a fact too well known to every large builder to require any further confirmation.

My opinion of the blue lias lime was derived from my own experience; supported by the testimony of many of our largest metropolitan builders. If your correspondent doubts the truth of my statement, he may easily judge for himself, by inspecting the Charing Cross Hospital, the Blind Asylum, St. George's Fields, the Athenæum Club House, the new buildings in Belgrave-square, &c., all of which are covered with the blue lias lime.

His comparison of the analysis of Atkinson's and Parker's cement only proves the correctness of my statement, that the difference between those two substances was comparatively trivial. Yours, &c.

C. L. O.

BIRMINGHAM RAILWAY TERMINUS.

Sir,—While admiring the noble railway terminus the other day, I was also greatly astonished and vexed at observing the disgusting condition in which it already is in some parts; for if the practices now tolerated be not speedily put a stop to, in a very short time all the base of the structure will be as filthy as the staircases of some of the Roman palaces, and this majestic propylæum will look like an approach to the temple of Cloacina. There can, surely, be no more difficulty in preserving it from such defilement than there is in protecting other public buildings from similar offences. I should conceive even much less, because, as the place is always open, there must always be some one or other attached to the establishment upon the spot.

Nevertheless, the building seems at present quite abandoned to the *discretion* of the neighbourhood; for I observed a number of dirty boys amusing themselves by scrambling between the columns and bronzed railing, although the latter was then but just put up. Unless all this be speedily put a stop to, the railing, the columns, and every part within reach will be greatly injured, in appearance at least. The bronzing of the gates will be rubbed off, perhaps the columns themselves scrawled and scribbled upon; and then people will probably complain of what ought never to have been suffered to occur.

Is there not a single porter—not one policeman in attendance? Some steps should be taken to prevent the shameful nuisances now permitted. Therefore, unless they have in the interval been adopted, I trust that this letter will have the effect of calling the attention either of the architect or some other individual interested in the building, to the abominations here complained of. CIVIS.

FRICTION WHEEL CARRIAGES.

Sir,—In No. IX. of your journal, I observe a description, accompanied by a drawing, of "Coles's Patent Friction Wheel Carriage." The Patentee states that "my invention" is "novel and important;" he denominates the carriages as "my Friction Wheel Carriages."

In a work entitled "Mechanics or the Doctrine of Motion," by W. Emerson, you will find an account of "Wheel Carriages:" to which he adds the following:—"To make the friction as little as possible, some have applied friction wheels;" and then proceeds to describe them with a plate and references.

That your correspondent cannot claim the invention as his own, is evident, for others have applied friction wheels; neither is it a "novel invention," as the date of "Emerson's Mechanics" is A.D. 1769; nor is it an important invention, or it would by this time have been generally adopted.

W. L. B.

[Our correspondent appears to have in some degree misapprehended Mr. Coles's expression. We think he applies the epithets "novel and important" plainly to "another part of my invention;" viz., the "elastic spring buffer" &c., which he goes on to describe.—Ed.]

ARCHITECTURAL SOCIETY.

Sir,—In your notice of the endeavour made to unite the Architectural Society with the Institute of British Architects, and of the meeting at which the Society determined it not to be desirable to form a junction with the Institute upon the terms contained in the scheme, you proceed to state that, "on the same evening, Messrs. Walker, Ferry, Moore, Wright, Bury, Lee Parish, Woodthorpe, Brandon, and Flower, ceased to be members; Messrs. Johnston and Watson have since withdrawn;" and that "the Architectural Society, thus deprived of its chief members, we fear may be considered as so much crippled in its usefulness, as to be virtually dissolved."

As one who has the honour of being a constant visitor to the public meetings of the Architectural Society, and intimately acquainted with several of those gentlemen who so laudably *established* that institution, permit me to correct your statement with regard to its being deprived of its chief members by the secession of those gentlemen you have named.

Without venturing an opinion whether your fears that "the Architectural Society, thus deprived of its chief members, may be considered as so much crippled in its usefulness as to be virtually dissolved," it is sufficient to inform you, that those gentlemen who have ever taken its interests into their consideration, and supported it by their exertions, abilities, and funds, and who have proved their determination to maintain at least the dignity and privileges of *every member* of their society, still compose the Architectural Society, to which I am sure you, with myself, wish every possible support and success; for whilst pursuing its course in unassuming modesty, it is laying the foundation of a new era, when the practice of architecture will be entrusted to *those alone* whose qualifications are based upon probationary study, under a professor, and authenticated proof of *personal talent in design* and knowledge of the sciences connected with their profession.

Yours, &c.,

T. SQUARE.

ANTI-OXYDATION OF METALS.

In one of our recent numbers we drew the attention of our readers to the important invention of Dr. Wall, for the prevention of corrosion of copper and other metals; we have now the satisfaction to state, that the experiments upon copper sheeting, as also upon the iron water tanks used in the naval service of the country, have been eminently successful, and fully test the value and national importance of the process adopted by the ingenious inventor.

SUGGESTIONS FOR AN IMPROVED METHOD OF LAYING A LINE OF RAILWAY.

It appears to be established among engineers, that continuous longitudinal timber bearings are far preferable to isolated stone blocks for laying the rails on, the motion of the trains being much easier, the road kept in repair at a much cheaper rate, and the damage to the engines and carriages considerably less; in addition to which, there is a considerable saving in the first outlay. It has been stated by some of our most experienced engineers, that a certain degree of *elasticity* is necessary for perfection in the upper works of a railway; and it further appears, that on the Great Western Railway, where the longitudinal sleepers have been laid on transoms and piles, that a harshness or percussion has been experienced by the carriages at the points where they are connected, which may be wholly attributed to the unyielding and non-elastic nature of the connecting points. Indeed, according to published reports and documents, the longitudinal sleepers on the Great Western and other lines of railway, where this method has been adopted, are in future to be retained in their places by ballasting only. But it appears there is also an objection to this, which is the difficulty of getting a firm and uniform bearing whereon to lay the timber, which having scarcely any weight in itself (in comparison with what passes over it), lies loose on the surface, subject to continual disarrangement. What I am about to propose may or may not remedy the evil; it is simply this—firmly to bed stone blocks at certain intervals, but larger and of a rougher kind than those used for fixing the chains to in the present method of laying the rails. On these blocks I would lay timber of a larger scantling than usually employed for longitudinal sleepers, and which I would firmly attach to the stone blocks, either by treenails, or bolts and plates passing quite through the stone blocks and timber sleepers. I cannot say at what intervals 'twould be advisable to lay th se stone blocks, but if at any considerable distance, packing to a limited extent might be adopted between the blocks; but if laid within a few feet ofe each other, I do not conceive that any additional support than that furnished by the stone blocks would be necessary, and from the stiffness of the scantling a light rail screwed or spiked down, may be used without sensible deflection being produced, however great the weight rolling over it. I should not suppose that this method would involve much greater expense than the present system of stone blocks, as a much lighter rail would suffice, chains would be dispensed with, and if packing was not necessary, the timber from its under surface not being bedded in the ground would be kept drier, and consequently more free from decay.

PETER BRUFF.

Charlotte-street, Bloomsbury.

[By reference to our first number, fig. 9, page 1, it will be found that the Americans have a similar method of laying their rails. We are inclined to believe that isolated supporters, whether it be by way of piles or stone sleepers, would be equally objectionable; they are both intended for the same purpose, to *support* the longitudinal sleepers, or they are of no service, and in our opinion, both would produce the same effect on the locomotive engines and the rails.—Ed. C. E. and A. Journal.]

PUBLIC BUILDING AT RUGBY.

(From a Correspondent.)

In July last an advertisement appeared in the public papers, inviting architects to send in designs for the above object, to comprise Town Hall, magistrates'-room, news-room, library, museum, and other accommodations, for which a premium of twenty guineas was offered. The cost of the building was not to exceed 2,500*l.*, and only three weeks were allowed to prepare the drawings. The premium offered seemed very inadequate, and the time too limited; however, many architects were induced to prepare designs, as the subject was by no means a complex one, and the premium was a gift from Mr. Wratislaw, the solicitor, who, with a public spirit which does him great credit, was anxious to elicit a design which might be creditable to the town. Sixty-four designs were sent in by respectable architects from all parts of the country, and exhibited at Mr. Wratislaw's house, on the 25th of August, when that by Mr. Eginton, of Worcester, was selected. A list of the competitors, and a polite letter of thanks, were sent to the several architects with their drawings, which had been forwarded to Rugby, and also returned to their authors free of expense. We are thus minute in these particulars, as one of the gentlemen, who submitted designs, received an anonymous letter, per post, from Manchester the other day, reproaching him for having entered the lists as a competitor, and couched in terms of the most filthy and coarsest description.

If the preceding statement should reach the eye of the anonymous writer, he will there see how mistaken he is in his facts, and will learn, perhaps, to blush at his disgraceful conduct, upon knowing that every reasonable assurance was held out, that the successful candidate, if an architect of well known reputation and respectability of character, would, doubtless, be employed to carry his design into execution.

Wooden Pavements.—The experiment of wooden pavements seems to have been fairly tried in Philadelphia. The success which has attended the efforts in Walnut Street and Chesnut Street is conclusive of the adaptation of that pavement in city streets. Of the duration, positive and comparative, of wooden pavements, it is of course impossible yet to speak, but it may be said that in several streets of the city stone pavements have exhibited strong evidences of needing repair in less time than the wooden pavement in use.—*Philadelphia Courier and Inquirer.*

BLOWING UP OF THE BOYNE.

Considerable curiosity was excited in Portsmouth to witness Mr. Abbinet's experiment of blowing up the wreck of the Boyne, off Southsea Castle, which was burnt and sunk in 1795. This wreck has ever since been a disgrace to the naval energies of this country, affording as it did an obstruction to all coasters and vessels of light draught of water. When Abbinet first made an effort to remove it parts of it were only four feet under water; at this moment there is not less than 18 feet over every part at low water, and therefore great good has been done to the navigation of Spithead and the port purely by dint of private exertion. About four years ago Mr. Abbinet, with a magazine of 200lb. of powder, blew off about 30 feet of the sternmost part of the wreck; and it was only in the spring of this year that he brought into harbour a mass of timber weighing at least 30 tons, a portion of the result of that explosion. We mention the time of this first experiment to show that Colonel Pasley's late experiments in the River Thames were by no means original ones. On the present occasion 630lb. of powder were exploded, and this was enclosed in an oil hogshead, into which two stop cocks were inserted; to these were attached two leaden tube pipes, containing an igniting match of 45 feet in length; at the upper end of each portfires were attached, which would burn about four minutes. When the pipes were attached, the magazine was very gently lowered into the water, and as it sank it was hauled into the situation intended by means of a rope leading through a block, previously lashed to or near the kelson of the wreck. The part fixed on was under the larboard bilge, abreast the main chains, with at least 20 feet of the bottom overhanging; the ship was lying on the opposite bilge. At this place about 30 feet of the bottom aft was entire, this is now destroyed or laid flat, as well also as the bottom for 40 feet forward. The whole wreck now therefore is dispersed on the ground, the fore part having been destroyed in the original burning; and as the tides, which run pretty strong over the spot, will no doubt soon wash off the mud which has accumulated to some feet in depth, Mr. Abbinet will be able to pick up the various portions, the most valuable of which are copper bolts and copper sheathing. The guns have been already nearly all picked up. When the magazine was safely landed, the two portfires, with the upper ends of the lead tubes projecting upwards about two feet, were securely lashed to an 18-gallon cask as a float; all boats and vessels were now ordered to withdraw, and Abbinet having fired the matches, withdrew himself. On the explosion taking place, a huge mass of water, about 40 feet square, rose up in a solid bulk for about six feet high, and then broke in the centre, throwing up several foamy columns for about ten feet higher. A low report was heard, as of a heavy explosion at a great distance, but no flame was apparent, nor was there any smoke; we imagine, however, if it had been dark, that a flame would have been seen to issue from the water. The day was beautifully fine; nearly 100 boats, filled with parties, were assembled; and it was quite amusing to witness the subsequent scrambling for fishes which were stunned or stupified, and to the number of hundreds came up floating on the water. The Port-Admiral, Sir Philip Durham, was present, and as the experiment was intended to have taken place on the preceding day, it would have been a singular incident that he should then have been present at the blowing up of one ship, as flag-officer of the port, on the 56th anniversary of the sinking of his own ship, the Royal George, near the same spot, at a time when he was junior lieutenant of her.—*Hampshire Telegraph*, Sept., 1838.

PREPARED FUEL.

In the course of the successive days of last week, a series of trials have taken place at Woolwich Dockyard, the principal establishment for her Majesty's steamers, under the superintendence of Messrs. Kingston and Dinnen, the former being the oldest engineer in her Majesty's navy, whose experience therefore for this important object induced the government authorities to place the testing of the invention under his immediate inspection. The grand desideratum for sea-going steam vessels, is considered to be the concentration of inflammable matter in as small a compass as possible; both on account of economy and of the stowage of munitions of war and provisions. The invention under trial is termed "prepared fuel," and is a composition of "screened" (otherwise almost uselessly small) coal, river mud, and tar, cast into blocks of the same size and shape as common bricks. An engine was worked with this "prepared fuel" on Tuesday; the consumption for six hours forty-five minutes, was seven hundred and fifty pounds. On Wednesday, the same engine was employed for the same period of time; and it required eleven hundred and sixty-five pounds of "north country coals" to keep it going: showing a saving of four hundred and fifteen pounds in favour of the "prepared fuel." On Thursday "Welsh coal" was used, and one thousand and forty-six pounds were consumed; and on Friday, "Pontop" coals being supplied to the engine, one thousand and ninety-eight pounds were required to work the engine for the six hours and forty-five minutes. On Saturday, six hundred and eighty pounds of the "prepared fuel" easily performed the same work; thus showing a reduction of expenditure of four hundred and eighteen pounds in favour of the invention. It is also highly necessary to point out that, on the average of the consecutive days, it required about fifty pounds less of the "prepared fuel" to "get steam up," which was not only better maintained by very little "feeding," but more readily obtained by the inflammable nature of the material. The "prepared fuel" will, no doubt, be generally adopted throughout the service; as, in addition to its excellency of quality for the purpose designed, it has the advantage of being "stowed away" in a compact state, and is not liable to act as a shifting ballast.—*Shipping Gazette*, *August* 8.

ABSORBED AND EFFECTIVE POWER OF LOCOMOTIVE ENGINES.

(From the Irish Railway Report.)

One of the first points to be considered in reference to the mechanical advantages of railway communication in comparison with canals and the usual road traffic, is the amount of power which must necessarily be expended before any force of traction can be communicated to the load. This expenditure, or absorption of power, far exceeds what would, in the first view of the question, appear at all probable. Few persons, perhaps, are aware, that the power absorbed in the largest of the engines at present employed on the Liverpool and Manchester line, in order to put the engine, &c., in a condition to move, and independently of any power applied to the motion of the load itself, amounts to about one-third of the whole power expended; yet such is the case, and it will be seen, therefore, how essential it is to the success of any railway undertaking, with locomotive power, that a very great amount of goods and passengers should be conveyed, and these not in small detached portions, but in large masses.

In fact a large and abundant traffic is essentially necessary to the success of any railway, undertaken as a matter of profitable speculation to its subscribers; and although there are certainly cases, where a line is opening the resources of a country, in which a less amount of present revenue may be held sufficient, yet it is proper that a full and satisfactory illustration should be given of the great proportional increase of charge per ton per mile, which would necessarily be incurred in the case of a deficient or inconsiderable traffic.

As part of the above statement may appear extraordinary, and as we believe that the subject has not been hitherto generally comprehended, it will be proper to point out the sources to which this absorption of power may be traced. These are:—

1st. The friction of the engine gear, independently of any load.

2nd. The friction of the wheels, axles, &c., of the locomotive itself.

3rd. The friction of the wheels, axles, &c., of the tender.

4th. The constant resisting pressure of the atmosphere to the motion of the pistons: all which retardations must necessarily be overcome before any remaining force can be made applicable to the traction of the load.

We have not thought it advisable to introduce the numerical computations on this head into the body of the report, but by referring to the note below, it will be seen that we may assume in general very nearly one-third of the whole steam power employed, as absorbed in what may be termed "preparing to move a load," and this is the same for great or for small loads; the consequence is, as shown in the note referred to, that the relative expenditure of steam power per ton per mile is nearly six times greater for a load of ten tons, than for one of 100 tons, and so on in different proportions for other defective loads. The same relative increased expenditure is incurred for wages to the engineer, stoker, and other persons engaged in conducting the loads. The expense of wear and tear of the engine bears at least the same ratio, not to mention all the fixed expenses of direction, stations, gatekeepers, road-attendants, &c., which will obviously be increased in a still higher proportion.

The question here, however, is merely the relative cost of working with different loads, which is reduced to a tabulated form, in the note above quoted.

NOTE.

The amount of the three former resistances above referred to, depend in some measure upon the perfection of workmanship, and have been found to differ in different engines; but from the best information we have been able to collect, and upon which we conceive reliance may be placed, these several retarding forces may be taken at a medium as below, viz.:—

First, The friction of the engine gear, independently of any load, is equivalent to 6lbs. per ton for the weight of the engine applied at the circumference of the wheel.

That is, supposing the engine to be raised from the ground, and a power applied to the circumference of the wheel, it would require an amount of force of 6lb. per ton to cause the wheels to work the piston and engine gear, both sides of the piston being open to the atmosphere; therefore, conversely, when the pistons work the wheels, this same amount of steam power must be expended to put the gear in motion.

Secondly, The friction and resistance of the locomotive itself, independently of the engine gear, is 8lbs. per ton applied to the circumference of the wheel.

That is, the engine gear being detached from the wheel, it will require a force of traction of 8lbs. per ton to balance the resistance due to the friction of the axles, and to the retardation on the line of way.

Thirdly, The friction of the tender itself, including the increase of friction brought on the engine gear, is 9lbs. per ton of its own weight.

Fourthly, The last resistance, *i. e.*, the atmospheric pressure on the piston, is necessarily 14.7lbs. per square inch, or 11½lbs. per circular inch on the area of both pistons. But this force being employed at the extremity of the piston rod, and being overcome only with the velocity of the piston, must be reduced according to the relative ratio of the velocities of the wheel and piston, which is different in different engines.* (See Pambour on Locomotive Engines.)

Before we can, therefore, exhibit numerically the amount of this retardation, it is necessary to state the dimensions of the several engines, which, after six years' experience, the directors of the Liverpool and Manchester [illegible] other railway companies, have found it expedient to adopt.

These are as below:—

Classes.	Cylinders, Diam. of.	Piston, Stroke of.	Wheel, Diam. of.	Engine, Weight of Tons.	Tender, Weight of. Tons.
1	14 inches	16 inches	4 feet 6 inches.	12	6
2	12 „	16 „	5 „ 0 „	12	6
3	11 „	18 „	5 „ 0 „	8½	5½
4	11 „	16 „	5 „ 0 „	8½	5½

In all these engines the pressure exhibited by the safety valve is 50lbs. per square inch, and, therefore, the actual elastic power of the steam in the boiler is 50lbs. added to 14.7lbs. or 64.7lbs. per square inch.

With these data the amount of absorbed power in these several cases is easily computed.

First Class—Friction of Engine gear	- -	6 × 12 = 72lbs.
Do. Locomotive	- -	8 × 12 = 96 „
Do. Tender	- -	9 × 6 = 54 „
		222lbs.
Area of both pistons, 307.8 square inches, at 14.7lbs. per square inch. Reduced in the inverse proportion of the double stroke of the piston to the circumference of driving wheel, gives	- - - - - - -	853 „
Absorbed power	- -	1,075lbs.

Now, on a good road, and with a well-made carriage, 1lb. is generally estimated to draw 30lbs. The power thus absorbed, therefore, in what may be termed the *preparation for motion*, with the first class locomotives, is sufficient to draw 32,250lbs.; viz., more than fourteen tons on a good road by horse power. And again, on a canal with the usual barges, 1lb. will draw, at 2½ miles per hour, 400lbs. of useful load, viz., independently of the weight of the barges; this absorbed power would, therefore, draw 430,000lbs., which is more than 190 tons.

In a similar manner, the amount of absorbed power in the three other classes is found as below:—

Second Class—Friction of Engine gear	- - - -	72lbs.
Do. Locomotive	- - - -	96 „
Do. Tender	- - - -	54 „
Atmospheric pressure on 226.2 inches, at 14.7lbs. reduced in the ration 5.9 to 1	-	564 „
Absorbed power	- -	786lbs.
Third Class—Friction of Engine gear	- - - -	51 lbs.
Do. Locomotive	- - - -	68 „
Do. Tender	- - - -	49½ „
Atmospheric pressure on 190.06 inches reduced in in the ratio of 5.23 to 1	-	533½ „
Absorbed power	- -	702lbs.
Fourth Class—Friction of Engine gear	- - - -	51 lbs.
Do. Locomotive	- - - -	68 „
Do. Tender	- - - -	49½ „
Atmospheric pressure on 190.06 inches at 14.7 per inch, reduced as 5.9 to 1	-	471½ „
Absorbed power	- -	640lbs.

Now the whole power of these several engines is found by multiplying the area of their respective pistons by the pressure (64.7lbs.), and then reducing this product to the circumference of the wheel.

In this way it will be found that the

	Class 1st.	Class 2nd.	Class 3rd.	Class 4th.
Whole power is -	3,755	2,488	2,337	2,090
Absorbed power -	1,075	786	702	640

It thus appears that the absorbed power is nearly one-third of the whole power of the engine.

This absorption necessarily takes place, whether the whole power of the engine be required or not; and hence again is seen the advantage of large loads, that the engines may always have their full duty to perform.

Having found the whole amount of engine power, and the amount of absorbed power, it is easy to find the extreme load the engine is capable of drawing, the data for this determination being as follows:—

The mean force necessary to overcome the friction of the best constructed carriages and waggons on a level line amounts to 8lbs. per ton of the gross

* This ratio is that of the double stroke of the piston to the circumference of the driving wheels. It is a well known principle in mechanics, that when a force is transferred from one part of a system to another, the product of the pressure into the velocity is constant.

The product of the pressure of the piston into the velocity of the piston is equal to the product of the resulting pressure to the axle into the velocity of the axle, which is to the former velocity as the circumference of the wheel to the double stroke of the piston.

load (that is, of the weight of the load and carriages inclusive,) and 1lb. per ton additional of the said gross load, for the extra friction brought on the engine gear; in all 9lbs. per ton.

Hence, therefore,

		1st Class Engine.	2nd Class.	3rd Class.	4th Class.
Whole power	-	3,755	2,488	2,337	2,090
Absorbed power	-	1,075	786	702	640
		9) 2,680	9) 1,702	9) 1,635	9) 1,440
		297 tons.	189 tons.	182 tons.	160 tons.

There is, however, another limit to the power of an engine, viz.—the adhesion between the wheels and the rails. The amount of which, according to a set of experiments on frictions by George Rennie, Esq., and published in the Philosophical Transactions for 1827, is about $\frac{10}{67}$ths of the pressing weight: so that assuming the weight on the driving wheels to be 6 tons, the greatest power of adhesion is 2,000lbs., and the greatest load about 222 tons; such loads, however, are seldom applied except as a mere matter of experiment.

Now, theoretically, the most advantageous load, as a matter of economy, would be the greatest practical load the engine is capable of drawing, supposing the plane to be every where horizontal; but as the engines and trains generally have to ascend planes which require great additional force of traction, the load seldom amounts to so much as half the greatest load the engine is capable of drawing on a level; but taking every thing into account, it is still most economical to take the greatest load that, under all circumstances, is practicable.

In the following, Table 1, column 2, there is given the amount of steam pressure requisite for different loads, from 10 tons to 290 tons, which is formed by simply adding to the absorbed power 9lbs. per ton, and it thus appears that in the first class engine

A load of 10 tons requires - - 1,075 + 90 = 1,165lbs.
A load of 100 tons requires - - 1,075 + 900 = 1,975 "

That is, ten times the load is drawn by considerably less than double the power: as the loads increase in weight towards 100 tons, which is assumed as the ordinary load, the unfavourable comparison in respect to the amount of fuel diminishes, and beyond that load the expenditure is less than in the medium case.

In order to exhibit the relation in this respect, in all practicable cases, the proportional amount of power per ton per mile, or for any distance, is computed and given in the fourth column of Table 1. The numbers are found thus:—the power required for 100 tons is 1,975lbs. or 19.75lbs. per ton, and for 10 tons 1,165 or 116.5lbs. per ton, then denoting the former by unity—

$$19.75 \ : \ 116.5 \ : : \ 1 \ : \ 5.89$$

That is, the quantity of power per ton per mile with 10 tons, is very nearly six times as great as with 100 tons. In the same way all the other numbers in the fourth column are computed.

The third column exhibits the relative velocities attainable with different loads; these numbers are thus obtained. The second column exhibiting the constant piston pressure required, and the power of the engine or the supply of steam being supposed constant, the velocities will be inversely as these pressures; that is, the velocity with which steam can be produced of a power represented by 1,975, is to the velocity with a pressure 1,165, inversely as 1,975 : 1,165, or as $\frac{1}{1975} : \frac{1}{1165}$.

Therefore, calling the former velocity 1, the latter will be 1.70, or 10 tons will be carried with $1.\frac{7}{10}$ times the speed of 100 tons. In a similar way all the numbers in the third column have been obtained.

At present we have only spoken of the excess of expenditure for fuel, but it will be seen that every expense is increased in a greater or less degree with small loads. The time of the engineer and assistants for example, costs as much per hour with small loads as with great loads, and therefore, if the time of the journey were the same, the expense per ton for wages would be ten times as great with 10 tons as with 100 tons, but the time is not the same; the expense per ton per mile, therefore, is directly as the time, and inversely as the load, or inversely as the load and velocity; representing therefore again, the expense per ton for locomotive attendance for 100 tons by unity; the expense per ton for 10 tons is to that for 100, as $\frac{1}{10} \times 1.7$ to $\frac{1}{100} \times 1$, or as 100 to 1.7, or as 5.98 to 1. In this way the several numbers in the fifth colum are computed.

Another important expense attending locomotive power is the wear and tear of the engine, and of the rails, chairs, &c.; but this item is not so easily reduced to numerical results as those considered above. It is not perhaps an unreasonable assumption, that an engine sustains as much or even more injury by passing a certain distance with a load of 10 tons, at the rate of 34 miles per hour, as with the load of 100 tons at the rate of 20 miles per hour, which would make the expense per ton per mile inversely as the load, and, therefore, the wear per ton ten times as great with ten tons as with 100 tons. But if we take only the momentary wear and tear to be constant, we shall have as in the case of wages, the charges for this item per ton per mile, inversely proportional to the load and velocity, and, therefore, expressible by the same number as in the preceding cases: these are given in the sixth column. In a way similar to that which has been described for the formation of Table 1, for engines of the first class; Tables 2, 3, and 4 have been computed for the other class of engines, the only difference being, that in these the medium load is taken at 80 tons in the second and third class engines, and at 60 tons in the fourth instead of 100 tons.

TABLES showing the Steam Pressure required in the Cylinders for different Loads; the relative Velocity with those Loads; and the relative Expense of Haulage per Ton per Mile.

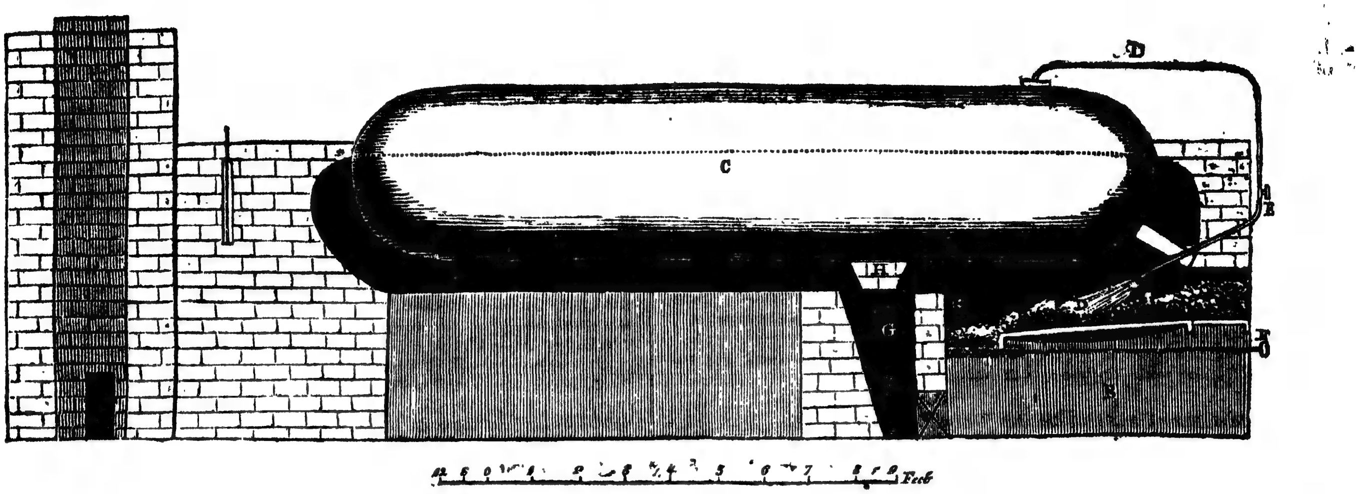
ECONOMY OF FUEL AND PREVENTION OF SMOKE.

(Extracted from the Mining Journal.)



The process consists merely of the admission into the furnace of steam in small quantities, through a tube D, taken from the boiler, and discharged over the fuel A, at any expedient place. The best and easiest mode appears to us to be by the introduction of the pipe conveying the steam immediately above the door of the furnace, with a fan-shaped termination reaching beyond the dumb-plate, and perforated with minute apertures, so as to throw the steam in small jets down upon and over the fire. One effect produced is the absolute prevention of smoke; another, the operation of the fire is fully doubled, and the steam employed itself consumed. The bridge of the furnace should, however, be raised rather higher than usual; and a little behind the bridge, another, in the form of an inverted arch, should be placed, so that, in meeting the current of the flame, it may direct it downwards, by which a large portion of the ashes and refuse of the fire is precipitated. The employment of steam, we need hardly observe, greatly increases the draught of the chimney.

The following is a brief statement of the trial to which the process was subjected in our presence, being taken from a copy of rough notes made on the occasion:—

On Monday, the 27th August, in the presence of the patentees, Dr. Fyfe, and other scientific gentlemen, we attended at the Castle Silk Mills, to witness the application of the process.

To enable our readers to accompany us in this experiment, we must inform them that the factory where the patent is applied is a building of hewn stone, which, from its magnitude and design, may vie with any similar structure in the kingdom. Its object is the spinning of silk from the "waste," as it is termed, or what, in mining language, would be called the "halvans," or "attle." The machinery, which is peculiarly beautiful, is worked by steam power, and to a portion is applied a ten-horse high-pressure engine. The nuisance created by its smoke in the vicinage, and the erection of two additional engines, each of seventy-horse power, directed the attention of Mr. Ivison, the manager, to the best means of consuming the smoke, and its necessary sequence, a saving of fuel. How successfully, will be better appreciated by giving our readers a recital of what we ourselves witnessed, and, moreover, renders any praise of the skill and ingenuity of the inventor (Mr. Ivison) superfluous.

The steam in the boiler being at a working temperature, we examined the state of the fire on commencing the experiment. The cistern from which the boiler is supplied was filled, and 392lbs. of coal weighed to the stoker. At half-past two o'clock the engine went to her work, and as the cistern required additional water, from the evaporation going on, it was measured in; the whole quantity taken during the experiment, of five hours' duration, being 504 gallons, or 5,040lbs. At half-past eight o'clock, the furnace, boiler, and cistern, were re-examined, and found to be in a similar state as when the experiment commenced; the actual consumption during the five hours being, as already stated, 392lbs. of coal, giving a result of 5,040lbs. of water evaporated, or 12.88*lbs. of water evaporated by one pound of coal*; thus proving that an *increase* of steam, *equal to* 115 *per cent.*, had been acquired by the application of the process of simply throwing in a jet of steam upon the fire.

Thus far the proof was adduced of the saving of fuel, and our attention was next directed to the prevention of smoke, although we should observe, that during the experiments no smoke whatever issued from the chimney. Fresh coal was therefore put on the fire, and in the course of a few minutes we had a succession of trials, when the smoke, issuing as on ordinary occasions, ceased almost momentarily on turning on the steam-jet—the interval being about eight *seconds*.

The boiler is worked at a pressure of 35lbs. on the square inch, and the quantity of steam injected into the furnace is calculated at about one-tenth of that generated. We should mention, that the surplusage of water supplied to the boiler is returned by a pipe, communicating with the cistern, so that all the water employed or taken is entirely evaporated, and thus obviates any question which might arise in testing the quantity of steam generated by a given quantity of fuel. We may add, that the coal used was an inferior Scotch coal, and that the boiler and furnace were certainly not in the best order, although the engine was doing her regular work, the experiment having been made for our satisfaction, without unnecessarily interfering with the business of the factory.

This invention will be highly important, from its applicability to locomotive engines, where coal in lieu of coke may be used; and we cannot but think that it may be applied to many domestic purposes. To the maritime interests the saving of tonnage, and the advantages from fewer depots, are too obvious to particularize.

It may not be amiss, in closing our notes on this important discovery, to observe, that the quantity of coal consumed in working the engine for twelve hours would be 940lbs., or 8cwt. 1qr. 16lbs., and which would evaporate 12,096lbs. of water, being an *excess* of 6,456lbs. over the present mode of generating steam—the price delivered being from 5s. to 10s. per ton. The coal used on this occasion was rendered at 5s. per ton, but assuming the average to be 7s. 6d., the cost of working the engine would in such case be about 3s. per day of twelve hours; and when the work performed by machinery, so set in motion, is compared with that which would be accomplished by manual labour, at a like cost, it seems almost incredible, while it affords a striking evidence of the ingenuity and powers of man, and of the advantages attendant their application.

We have received the following communication on the same subject, which will give some additional information:—

To the Editor of the Civil Engineer and Architect's Journal.

Sir,—In accordance with a suggestion by another of your subscribers, given in page 319 of your last publication, I beg to transmit to you an account of the working of the only effectual smoke-burner I have ever seen. Mr. Ivison, of this town, by means of a jet of steam, entirely prevents smoke, and saves fuel to an enormous extent. As I feel interested in the subject, I have taken part in the experiments, which indicate the amount of the saving effected in the fuel. The apparatus has been working for many months at the factory of Messrs. William Casey and Co., Fountain Bridge, upon a ten-horse high-pressure engine, and I give you, as near as I can, the average result of several trials, made whilst the engine was doing its ordinary work.

With the apparatus, 368lbs. of ordinary *Scotch* coal lasted about five hours, and evaporated 444 gallons of water.

Without the apparatus, 737lbs. of the same coal would only last five hours and a half (or half an hour longer), and evaporate 461 gallons of water.

The apparatus may be made by any smith, adapted to all kinds of furnaces, and fitted up at a few hours' notice, at a cost not exceeding fifty shillings for a single furnace. The patentee evidently wishes every body to take it, by the very moderate charge he makes for its use, which does not exceed 1*l.* per horse power per annum.

I should mention, I have begun to use it myself, and that it is being very generally adopted in this part, both on land and sea, with great success. I have every confidence in the invention, and would earnestly recommend it to the notice of your readers. Yours, &c.,

WILLIAM WATSON.

Main Point Foundry, Edinburgh,
September 18th, 1838.

GIRARD COLLEGE, PHILADELPHIA.

Through the kindness of a professional friend, we have been favoured with two pamphlets respecting the building above-mentioned, which is now in course of erection, under the care of Thomas U. Walter, Esq., Architect. From the description, it appears likely to be one of the most magnificent buildings erected in America; and a print of the elevation which we lately saw, strongly confirms the impression. The cost of the building will be defrayed from the munificent bequest of the founder whose name it bears. The following extracts from one of the pamphlets before alluded to, containing an account of the proceedings on laying the corner-stone, will give some idea of the origin and objects of the Institution.

Stephen Girard was born at Bordeaux, in France, on the 24th day of May, 1750. His first landing in the United States was at the Port of New York; the seat of his residence and successful enterprises was the City of Philadelphia; where he died the 20th day of December, 1831, devising, for the benefit of society, the most splendid donation that philanthropy has ever devoted.

This College, a portion of the beneficence of Stephen Girard, for the education of poor male orphans, was endowed by him with TWO MILLIONS OF DOLLARS.

Mr. Biddle, the President of the Trustees of the College, delivered on the occasion a most eloquent and impressive address, concluding it with these words:—

In the name of Stephen Girard, of the City of Philadelphia, in the Commonwealth of Pennsylvania, Merchant and Mariner, we lay the foundation of this Girard College for Orphans. We dedicate it to the cause of Charity, which not only feeds and clothes the destitute, but wisely confers the greatest blessings on the greatest sufferers;

To the cause of Education, which gives to human life its chief value;

To the cause of Morals, without which, knowledge were worse than unavailing; and finally,

To the cause of our Country, whose service is the noblest object to which knowledge and morals can be devoted.

Long may this structure stand, in its majestic simplicity, the pride and admiration of our latest posterity; long may it continue to yield its annual harvests of educated and moral citizens, to adorn and to defend our country. Long may each successive age enjoy its still increasing benefits, when time shall have filled its halls with the memory of the mighty dead who have been reared within them, and shed over its outward beauty the mellowing hues of a thousand years of renown.

The following is a description of the main building, by Mr. Walter, the architect:—

The Girard College is situated about one and a half miles North-West of the centre of the City, on a tract of land containing forty-five acres; the whole of which was appropriated by Mr. Girard exclusively to the purposes of the institution.

The main building, which is the subject of this description, is composed in the Corinthian order of Grecian architecture; it covers a space of 184 by 243 feet, and consists of an *octastyle* peripteral superstructure, resting upon a basement of eight feet in height, composed entirely of steps extending around the whole edifice; by which a pyramidal appearance is given to the substructure, and a means of approach to the porticoes afforded from every side. The dimensions of the stylobate (or platform on which the columns stand), are 159 feet on the fronts, by 217 feet on the flanks; and the cell, or body of the building, measures 111 feet by 169 feet 2 inches. The whole height, from the ground to the apex of the roof, is 100 feet.

The columns are thirty-four in number; the diameter of the shaft at the top of the base is six feet, and at the bottom of the capital five feet; the height of the capital is eight feet six inches, and its width, from the extreme corners of the abacus, nine feet; the whole height of the column, including capital and base, is fifty-five feet.

The entablature is sixteen feet three inches high, and the greatest projection of the cornice, from the face of the frieze, is four feet nine inches; the elevation of the pediment is twenty feet five inches, being one-ninth of the span.

The capitals of the columns are proportioned from those of the Monument of Lysicrates at Athens; they are divided in height into four courses,—the first embraces the water leaf, and consists of a single stone of seventeen inches in thickness;—the second course is also composed of a single stone, the height of which is two feet ten inches,—the annular row of acanthus leaves occupies the whole of this course;—the third division of the capital embraces the volutes and cauliculi,—this course, which is likewise two feet ten inches in height, is composed of two pieces, having the vertical joint between the cauliculi on two opposite faces;—the fourth, or upper course, being the abacus, is one foot five inches in height.

The ceiling of the portico will be formed by beams resting on the tenia, and extending from the cell of the building to the colonnade opposite to each column; the spaces between the beams will be filled in with rich lacunaria.

The corners of the building are finished with massive antæ, having bases and capitals composed upon the principles of Grecian architecture.

The flanks of the cell are pierced with windows, which are ornamented with the Greek antæ, surmounted with architraves and cornices.

The doors of entrance are in the centre of the North and South fronts; they are each sixteen feet wide in the clear, by thirty-two feet high; their outside finish consists of antepagmenta, of two feet seven inches wide, the supercilium of which is surmounted with a frieze and cornice;—the cornice is supported by rich consoles, of six and a half feet in height, and the cymatium is ornamented with sculptured honeysuckles.

The exterior of the whole structure will be composed of fine white marble, slightly tinted with blue.

The vestibules, which are approached by means of the doors at each end of the building, are ornamented with marble antæ, columns, and entablature, of the Greek Ionic order, which support a vaulted ceiling, consisting of elliptical groin arches, enriched with frets, guilloches, and lacunaria; the columns, which are sixteen in number, will each be composed of a single piece of marble;—the proportions of the order are from the Temple on the Ilyssus at Athens.

The lobbies in the second story are directly over the vestibules, and occupy the same space. The columns in this story, which are also sixteen in number, will be composed in the simplest form of Corinthian or foliated architecture, proportioned from those of the Tower of Andronicus Cyrrhestes at Athens; the entablature will be surmounted with groin arches, similar to those in the vestibules, the soffits of which will be enriched with lacunaria.

The stairways will all be composed of marble; they will be constructed in the four corners of the building, each occupying a space of twenty-two by twenty-six feet, extending the whole height of the edifice; these openings will each be crowned with a pendentive parabolic dome, surmounted with a skylight of ten feet in diameter—the height of the skylight from the floor will be eighty feet.

The building is three stories in height; each of which is twenty-five feet, from floor to floor: there are four rooms of fifty feet square in each story. Those of the first and second stories, are vaulted with groin arches; and those of the third story, with domes supported on pendentives, which spring from the corners of the rooms at the floor, and assume the form of a circle on the horizontal section at the height of nineteen feet. These rooms are lighted by means of skylights of sixteen feet in diameter. All the domes are terminated below the plane of the roof, and the skylights are designed to project but one foot above it, so as not to interfere with the character of the architecture.

The whole building will be warmed by means of furnaces, placed in the cellar; and every apartment will be ventilated upon philosophical principles

The other pamphlet contains the fifth annual Report of the Building Committee. Subjoined to it, there is a Report to the Committee from the Architect; from which we give the following extract:—

The expansible properties of iron having been a subject of considerable conjecture in reference to the bands for resisting the lateral pressure of the arches, I was induced to make an experiment for the purpose of discovering the actual difference of temperature produced in the middle of the walls, by the extreme heat of summer and the severest cold of winter.

Although I have never had an idea that any evil could possibly result from the expansion of the iron in question, by an increase of temperature, the materials which surround it being subject to an expansion almost (if not quite), equal to that of the iron, yet the satisfaction to be derived from positive evidence on the subject is sufficient to give interest to the experiment;—I shall therefore give a brief account of the manner in which it was conducted, so as to enable you to judge how far the result may be relied on.

The place selected for the experiment, was the brick wall between the South vestibule and the large rooms;—the thickness of this wall is five feet five inches, and its distance from the South front of the cell twenty-six feet; the sun had therefore full power upon it during the summer, and in the winter the whole building was covered with a temporary roof:—I should also remark, that the experiment was completed before any fires were made in the furnaces.

On the 23rd of September, 1836, the temperature on the work being at 82 degrees Fahrenheit, a self-registering minimum thermometer was placed upon the iron band in the middle of the wall, and the brick work constructed as solidly around it as the rest of the building.

On the 29th of July, 1837, the temperature being again at 82 degrees, a hole was made in the wall, and the thermometer taken out; when it was found that the register had descended to 42 degrees during the intermediate winter, the extreme cold of which was three degrees below zero:—thus we find the greatest cold in the middle of the walls to be 42 degrees.

On the 16th of January, 1837, the temperature on the building being 24 degrees Fahrenheit, a self-registering maximum thermometer was placed on the iron band in the middle of the aforementioned wall, on the same horizontal line with the other thermometer, and about sixty feet distant from it, a space having been left in the wall when it was built, for the purpose; which space was walled up around the thermometer, as firm and compact as the rest of the work.

On the 16th of December, 1838, the temperature on the building being again at 24 degrees, the walling was taken out; when it was found that the register in the thermometer had risen to 61 degrees during the intermediate summer, the greatest heat of which was 94 degrees.

We have therefore 42 degrees for the lowest temperature of the iron bars, and 61 degrees for the highest, making a difference of 19 degrees.

The expansion that an increase of temperature of 180 degrees produces upon malleable iron, is given by Dr. Ure, in his Dictionary of Chemistry, as follows:—

From experiments by Smeaton $\frac{1}{704}$ of its length; according to Borda's experiments $\frac{1}{865}$ of its length; and according to Dulong and Petit $\frac{1}{846}$ of its length.

Mr. Hassler (of New Jersey), in his "Account of Pyrometric Experiments," read before the American Philosophical Society, June 29th, 1817, finds the expansion to be equal to $\frac{1}{767}$ of its length; and in a work on Natural Philosophy, by Biot, we have the experiments of Lavoisier and Laplace, made in 1782, giving an expansion, under the same increase of temperature, equal to $\frac{1}{819}$ of its length.

The trifling difference in these results may be attributed to a difference in the density of the material:

Now, if 180 degrees will increase a bar $\frac{1}{773}$ of its length (this being the greatest expansion obtained by the foregoing experiments), 19 degrees will lengthen it only $\frac{1}{7326}$; hence the bands around the rooms of the College (each being 54 feet long from the points of support), will be subjected to a difference in their length between the extreme heat of summer and the severest cold of winter, of $\frac{1}{7326}$, or $\frac{1}{12}$ of an inch.

This being the actual difference produced in the length of the iron bands, by the greatest change of temperature to which they can be subjected, it remains for us to consider the expansibility of the materials with which they are surrounded.

A table of the expansion of different kinds of stone, &c., from an increase of temperature, is given by Mr. Alexander J. Adie, civil engineer, in a paper read before the Royal Society of Edinburgh, on the 20th of April, 1835,* in which he makes the expansion produced upon bricks by 180 degrees of Fahrenheit, equal to $\frac{1}{1818}$ of their length, or $\frac{1}{28}$ of an inch in 51 feet under an increase of temperature of 19 degrees.

If, therefore, the maximum expansion of one of the iron bands in the walls of the College is $\frac{1}{12}$ of an inch, and the brick work surrounding it $\frac{1}{26}$, the difference is then reduced to nearly $\frac{1}{22}$ of an inch:—but if we consider that the variation of temperature in the interior of the wall is only 19 degrees, while the exterior is subjected to the extremes of heat and cold, it will be obvious that the aggregate expansion and contraction of the brick work is even greater than that of the iron.

From these considerations, it is evident that not the slightest injury can possibly result from the use of iron in the construction of the College.

THATCHED HOUSE NUISANCES.

(Extracted from a very useful publication, "LOUDON'S SUBURBAN GARDENER AND VILLA COMPANION.")

A thatched cottage is an object of admiration with many persons who have not had much experience of country life, and accordingly we find several in the neighbourhood of London. Such cottages have, perhaps, the gable end covered with ivy, the chimney tops entwined with Virginian creepers, and the windows overshadowed by roses and jasmines. The ivy forms an excellent harbour for sparrows and other small birds, which build there in quantities in spring, and early in summer, and roost there during winter. In June, as soon as the young birds are fledged, all the cats in the neighbourhood are attracted by them, and take up their abode in the roof of the house every night for several weeks, the noise and other annoyances occasioned by which we need only allude to. We say nothing of the damp produced by the deciduous creepers and the roses, as we have already mentioned that, but we must here notice another evil, which is not so obvious, though quite as serious, and this is the numerous insects generated in the decaying thatch, and more especially that loathsome creature the earwig, which in autumn, whenever the windows are open, comes into the house in quantities, and finds its way into every closet, chink, piece of furniture, and even books and papers. All cottages of this kind harbour snails and slugs in the ivy, and spiders under the eaves of the thatched roof, and wherever there are spiders there are also abundance of flies. As there is always a garden attached to such cottages, it is almost certain, if on clayey soil, to abound in snails, slugs, worms, and, if the situation is low, perhaps newts. Some of these from the doors, or, at all events, the back door, being generally kept open, are quite sure to find their way, not only into the kitchen, but even into the pantry and cellars. Slugs, when very small, will enter a house through a crevice in the window or a crack in the door, find their way to the moist floor of the pantry or the cellar, and remain there for weeks, till they are of such a size that they cannot retreat. There are few persons, indeed, who do not experience a feeling of disgust at seeing the slimy traces of a slug in any part of their house, not to speak of finding them in dishes in which food is kept, or even on bread, or at discovering an earwig in their bed or on their linen. The kitchen, in low damp cottages of every kind, almost always swarm with beetles and cockroaches, and the pantry with flies; while, from the closeness and want of ventilation in the rooms, it is almost impossible to keep fleas, &c., from the beds. If a large dog be kept in or near the house, as it frequently is, or if a stable or cowhouse be near, the fleas from the dog, the horses, or the cows, which are larger than the common kind, will overspread the carpets, and find their way to the sofas and beds. Having lived in cottages of this kind in the neighbourhood of London, we have not stated a single annoyance that we have not ourselves experienced; and we have purposely admitted some. Two of these, offensive smells and rats, are the infallible results of the want of proper water-closets and drainage; but these evils, great as they may seem to be, are much easier to remedy than the others already mentioned, which are, in a great measure, inseparable from the kind of house. Two others, the danger of setting fire to a thatched roof, and its liability to be injured by high winds, are sufficiently obvious; but it would hardly occur to any one who had not lived in a house of this description in the neighbourhood of London, that a thatched roof is of all roofs the most expensive, [illegible] in repair. A plumber or a slater to repair a lead or a slate roof may be found everywhere in the suburbs of large towns; but a professional thatcher must be sent for from the interior of the country. For example, the nearest cottage-thatchers to London are in the hundreds of Essex on the east, and in Buckinghamshire on the west.

FAILURE OF A SUSPENSION BRIDGE.

A letter from Fribourg, in Switzerland, states that a few days since, all the surrounding population repaired to Corbieres, to witness the opening and proving of the strength of the new suspension bridge. At 12 o'clock, the principal authorities and engineers being present, a train of 20 carts laden with gravel, was made to cross the bridge, which bent but very slightly under the weight. The same train of carts was again drawn upon the bridge, and kept stationary, and to this weight was added that of a great number of the spectators; when instantly a loud crash was heard, and the bridge swung violently, in consequence of the two cylinders, over which the chains passed, and which rested on the two pyramids on the Corbieres side of the river, having given way, and broken into a thousand pieces. The terror and consternation were universal, but fortunately no person was injured; and the accident, which in no degree affects the question of the solidity of the bridge, will require only a short time to be repaired.—*Morning Post, August 2nd.*

BRITISH MUSEUM.

Estimate of the Expense of Completing the New Buildings.
(From a Parliamentary paper.)

The north-west building for the print-room, library, &c., estimated at 19,000*l.*, and since enlarged by direction of the trustees . . .	£20,500
The south front building, extending between the wings, with the portico, colonnade, &c.	82,000
The south-west building, and the colonnade adjoining it	60,000
The gallery at the western extremity of the south front	10,000
Arrangements proposed in the upper floor of east wing for the reception of the zoological and botanical collections	3,000
The officers' houses, with the secretary's offices and buildings, connecting them with the Museum	36,000
Probable expense of the iron palisading along the south and east fronts, entrance lodge, dwellings for the attendants and others, guard-house, forming and paving the front quadrangle, &c.	15,000
	£226,500

With the addition of 10 per cent. for contingencies, the total estimated charge will be 250,000*l.*, to be spread over the period of five or six years, that being the probable time which will be required for the proper execution of the works.

To this sum of 250,000*l.* there must be added the sum which will be required for the purchase of certain houses, ten in number, and the site they occupy, which are the property of his Grace the Duke of Bedford. The plans of Sir Robert Smirke are framed in some of their details upon the assumption that the buildings and site abovementioned, together with any interests in existing leases, can be purchased for a sum not exceeding their fair value.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

INSTITUTION OF CIVIL ENGINEERS.

REPORT OF PAPERS READ AND PROCEEDINGS, SESSION 1838.

(Continued from page 292.)

Thames Tunnel.

Mr. Brunel stated that they were at present* more inconvenienced by fire than by water. Some of the gases which issue forth, ignite very rapidly; and the reports from Guy's Hospital stated some of the men to be so injured by breathing these gases, that small hopes were entertained of their recovery. The explosions are frequent, and put out the candles of the workmen; but the largeness of the space prevents their being dangerous. The thickness of made ground above them is about 18 feet. He conceives that these deleterious gases issue from the mud of the river; they proceed from a corner at the top. They had used chloride of lime, but without any great success; there appeared no remedy for the inconvenience. The breathing the gas produces sickness.

Explosion of Steam Boilers.

A communication was read from Mr. Timperley, of Hull, on the explosion of the boiler of the Union steam-packet at that place last summer. This was attributed to the water in the boiler having become so far reduced as to lay bare the tops of the flues, which would probably be heated to a very high temperature. Water coming in contact with them in this state, on a slight lateral motion of the vessel, steam of sufficient intensity to produce the effects described might be produced.

Mr. Macneill stated that the boiler plates had in the above instance been rent across like a sheet of paper. There was not a single rivet broken.

A long discussion took place on the causes to which these extraordinary cases could be referred: the violence of the explosion on bursting, appearing greater than could be referred simply to the pressure of the steam. If the water were supposed to be decomposed by contact with the hot plates, some of the oxygen would be absorbed by the metal, and the proportion requisite

* See Journal, No. IV. page 76.

* May 15.

for an explosive mixture destroyed. But there were great difficulties in conceiving the decomposition of water by the plates of a boiler. The commission of the Franklin Institute concluded this to be impossible.*

It appeared then, that there were grounds for doubting the fact of the presence of oxygen, such as would cause an explosion. And it seemed almost unnecessary to resort to any such explanation, as the sudden generation of steam of high elasticity would produce a pressure sufficient to blow out or rend the boiler in the weakest part, before the pressure could be transmitted through the steam to the safety valve. The transmission of pressure through an elastic fluid requires time, but the action on the solid is instantaneous.

It was suggested whether a large portion of hot surface might not become suddenly exposed by the cracking off of the incrustation on the sides of the boiler. The metal expands more rapidly than the incrustation; portions of the latter may crack off and expose a large extent of hot surface to the steam and water; a sudden increase in the elastic force of the steam would necessarily ensue. The incrustation is itself a bad conductor of heat.

Mr. Field, in reply to a question respecting the rapid decay of the bottoms of copper boilers, stated, that copper is very rapidly injured by repeated heatings, and will not long bear high degrees of temperature.

Mr. Cubitt stated that he had not known of any case of explosion of a boiler containing plenty of water. With respect to a recent accident in America, which had taken place soon after the boat had started, he thought that a boiler was more likely to be short of water at starting than at any other time, for the steam will probably have been blowing off for some time, and the men have neglected to supply the boiler; whereas after the vessel has started, the pumps worked by the engine supply the boiler. He should think that a boiler is more likely to be short of water before or just after starting, than at any other time.

Mr. Field stated that the vessel had stopped, and the explosion took place while taking up a passenger; the safety valve had been held down. In all these cases of explosion the difficulty which he experienced was, how to account for the pressure being suddenly increased by the amount which must be supposed. It did not appear to him sufficient to suppose that water flowed over hot flues. If the whole of the top of the fire-place were red hot, this could not produce the effect. The steam boilers in America are generally of a form ill adapted to resist pressure.

Mr. Buddle stated that the only clearly ascertained fact seemed to be, that these explosions took place when the boilers are dry. He had a case of twin boilers, standing side by side; the dry one exploded; no cause could possibly be assigned but that it was dry. The steam communication betwixt the boilers was free, by a pipe *eight* inches diameter. It was not a collapse, but the boiler was torn into a thousand pieces. There are two distinct cases; the one a rent or bursting, the other an explosion, in which the parts are thrown to a considerable distance.

Mr. Cubitt called attention to the remarkable case mentioned by Mr. Buddle, of two boilers connected together by a steam pipe of eight inches diameter, the communication free betwixt them, but one short of water; the other having its proper quantity of water. The dry boiler blew up with a great explosion, the other remaining uninjured. The steam was blowing off at the time. With respect to the nature of the report, Mr. Buddle stated that he had not himself heard it, but it was represented as sudden and short; any representation of this nature cannot be depended on, as two persons situated in different positions will give very different accounts. This had occurred to his knowledge on the explosion of a coal mine. He was close by, and thrown down; the report was smart like that of a six-pounder; at two miles off, it was like a peel of thunder, shaking the houses and throwing down the furniture. One peculiar feature in the explosion of the steam boilers is the rending and crumpling up of the boiler plates. The plates are rent and twisted as if of paper.

Steam Expansion Table. By George Edwards, M. Inst. C.E.

A paper by Mr. Edwards was read, descriptive of the principle and method employed in dividing his Steam Expansion Table, an account of which had been laid before the Institution last session.

History and Construction of Westminster Bridge, accompanied with detailed Drawings. By F. Whishaw, M. Inst. C. E.

This account of Westminster Bridge has been extracted from the very voluminous documents in the Westminster Bridge Office, access to which was given to the author of this paper by the kindness of Mr. Swinburne, the resident engineer to the bridge.

The first act was passed in 1736, and empowered certain commissioners to raise moneys by lottery. Three sites were pitched upon; the Horse-ferry, over against the Palace Yard, and over against the Woolstaple, which latter was finally fixed on. The scheme was violently opposed by the city of London and the Thames watermen. The commissioners selected a very curious and well-designed wooden superstructure, by James King; but having determined that the bridge should be of stone, they accepted a proposal from Mr. Labelye to found one pier by means of caissons, and which he had offered to build at his own expense.

This bridge, so lasting a monument to the genius of Labelye, consists of fifteen semicircular arches, decreasing regularly in span by 4 feet from the centre, which measures 76 feet, to the sixth arch on each side, which is 52 feet in span; all the arches spring from the line of low water of 1736. The whole distance between the abutments is 1068 feet, with 870 feet clear waterway, and 198 feet solid. A peculiar feature in this bridge is, that the spandrels are formed of radiated Purbeck blocks, with occasional bond stones, and the interior filled with ballast and rubbish.

The design of Mr. Labelye was the only one for laying the foundations of the piers under water, and the application of caissons for this purpose then first took place. The construction of these caissons and method of founding the piers by means thereof are fully described and illustrated. The piles were driven by an engine invented by Mr. Valoue, a watchmaker; it was erected on a platform, fixed on the top of a barge, and worked by three horses walking round and turning an upright shaft, on which was fixed a large cog-wheel and a drum, on which the rope was wound, and passing by pulleys to the top of the guide frames was connected with a follower furnished with tongs, as in the common pile engine. The number of strokes in an hour was about 150, at an elevation of 9 feet; the weight of the ram 1700lbs. The piles were generally cut off; the time occupied in cutting off a pile about 15 inches square and 10 feet under water being not more than a minute and a half. The construction of the abutments and of the arches is fully described, and the quantity of stone employed in the middle 76-feet arch, and the two adjoining 72-feet, is stated; the expense of these three arches was £24,074.

The centres employed were on the principle of the diagonal truss; for the five middle arches three rows of piles were driven on each side to support the centres, and for the other arches only two rows. Each centre consisted of five ribs of fir timber, resting on transverse and longitudinal oaken plates. The five centres used on the Westminster side were afterwards used for the corresponding arches on the Surrey side; the striking of the centres was first performed by means of circular wedges of a peculiar construction; this mode, however, from its expense, was superseded by straight wedges.

A most interesting portion of the history is that which relates to the 15feet sunken pier. There was no piling under the caisson bottoms, and the removal of gravel of the bed of the river very near the pier in question occasioned consequently a sinking. The progress and nature of the sinking are accurately detailed. The south point had settled 14 inches and the north point 13 inches; and the sinking still going on, it was determined to remove the superstructure above the sunken pier and damaged arches; the sinking still continued, but at last appeared to stop, and the whole amount was found to be 3 feet 4 inches at the north-west angle, and 2 feet 7 inches at the south-east angle, of the pier. Centres were erected under the two damaged arches, the adoption of which plan was recommended to the commissioners in the following words:—"If the pier should settle much more, it is not in the power of any mortal agent or agents to hinder the arches from following it, as long as it is possible; and therefore, in that case, the two arches instead of parting asunder, and their materials falling into the river, and not to be taken up without a great expense of time and money, will be received and their materials supported and secured, in order to their being regularly unbuilt." The pier, however, lightened as above described, did not continue to sink, and the weight over the piers was considerably reduced by introducing segment arches over the 15 feet pier, and half arches over the adjoining piers, leaving a considerable void space beneath each.

Labelye presented to the commissioners several reports on the open joints, on the sunken pier, on the Surrey New Road, and on the completion of the works. These are most interesting, serving, as they do, to exhibit the state of engineering at that time in the country.

A detailed account is also given of the ingenious wooden superstructure designed by Mr. James King, and of Mr. Batty Langley's design for a wooden bridge at the Horse-ferry. The author has also collected, at immense pains, the prices of materials and of labour, as paid in the erection of Westminster Bridge; he has also compiled a journal of works from the commencement of the undertaking to the time the bridge was opened. These most interesting and instructive documents are collected from the voluminous records deposited in the Bridge Office.

The paper is accompanied by an atlas of eleven drawings, showing the site and all the details of the bridge, with facsimile signatures of Charles Labelye the engineer, and Messrs. Jelfe and Tufnell the contractors.

The Council of the Institution of Civil Engineers give notice that they will award, during the ensuing session, Telford premiums to communications of adequate merit on the following subjects:—

1. The nature and properties of steam, especially with reference to the quantity of water in a given bulk of steam in free communication with water at different temperatures, as deduced from actual experiment.

2. The warming and ventilating public buildings and apartments, with an account of the methods which have been most successfully employed for ensuring a healthy state of the atmosphere.

3. An account and drawings of the original construction and present state of the Plymouth breakwater.

4. The ratio, from actual experiment, of the velocity, load, and power, of locomotive engines on railways.

 1st. Upon levels.
 2nd. Upon inclined planes.

5. The sewage of Westminster.

6. Drawings and description of the outfall of the King's Scholar's Pond Sewer, and of other principal outfalls of the Westminster sewage; also, the inclination, dimensions, and forms, of the sewers, and the observed velocities, of water in them.

7. Drawings and descriptions of the sewage under the commission for Regent-street, especially of the outfall at Scotland Yard.

* See Report of Franklin Institute on the Explosion of Steam Boilers.

8. Drawings and description of the best machine for describing the profile of a road, and also for measuring the traction of different roads.

9. The alterations and improvements in Blackfriars Bridge.

10. The explosion of steam boilers.—Especially a record of facts connected with any explosions which have taken place: also, a description, drawings, and details, of the boiler, both before and after the explosion.

11. Drawings, sections, and descriptions, of iron steam vessels.

12. The comparative advantages of iron and wood, as employed in the construction of steam vessels.

13. The advantages and disadvantages of the hot and cold blast in the manufacture of iron, with statements of the quality and quantity of the materials employed, and produce thereof.

14. The causes of and means of preventing the changes in texture and composition which cast iron occasionally undergoes when in continued contact with sea water.

15. The properties and chemical constitution of the various kinds of coal.

The communications must be forwarded to the house of the Institution,* on or before the 30th of March, 1839.

It is not the wish of the Council to confine the Telford premiums to communications on the above subjects; other communications of distinguished merit and peculiarly deserving some mark of distinction, will be rewarded.

July 9, 1838. THOMAS WEBSTER, Secretary.

* All communications previous to the 25th of December, 1838, to be addressed to Cannon Row, Westminster; after this, to No. 25, Great George Street, Westminster.

ARCHITECTURAL SOCIETY.

We are happy to hear that there is no fear of this society being dissolved in consequence of the withdrawal of several members. We understand, that at the first meeting of the ensuing session, the names of several influential members of the profession will be announced as having joined the society; among whom are Messrs. Tite, George Smith, Ianson and Savage.

MANCHESTER ARCHITECTURAL SOCIETY.

On Wednesday Evening, 5th September, the Seventeenth General Meeting of this Society was held in their Rooms in Mosley street.

Mr. J. W. Hance, the secretary, read the first of a series of papers investigating the principles of a new system of perspective, which has created much sensation, invented by Mr. Parsey, of London, who, it will no doubt be remembered, delivered a course of lectures on the art in this town, in the early part of the present year. After a few prefatory remarks on the necessity of a knowledge of perspective to all who wished to attain even a tolerable proficiency in drawing, Mr. Hance proceeded to compare the principles of Mr. Parsey's system with those of the usual one, pointing out their discrepancies. Assuming as his data—1st, That for any art or science to be of practical utility, it must be based on sound principles, *invariable* and *immutable*; 2nd, That of two systems relating to art, that must be the better which is the *more simple in practice*, and whose results are more in accordance with *natural* effects; 3rd, That any practice, even if sanctioned by long custom, which can be proved to be founded on *false principles*, is unworthy of support, and should be discarded by those who are anxious to follow the truth. Mr. Hance remarked that perspective was generally defined as a section or cutting by the plane of delineation or picture, of the rays supposed to proceed from the object viewed to the eye of the observer, and was often familiarly illustrated by supposing a window, plate of glass, or other transparent plane, to be interposed between the eye and the object; the figure generated on the glass, &c. by the rays, would be the perspective representation of the object; and to perform this upon an opaque surface, such as paper or canvass, by mathematical rules, is the science of perspective. Upon the placing of the picture, or plane of delineation, the whole operation depends; and this was the point to which he should confine the present investigation. Great diversity of opinion prevailed about the mode of fixing this plane; but he thought he should be able to prove that Mr. Parsey's assertion was correct, "That we cannot *choose* the plane, but that Nature herself marked it out." All we have under our control in viewing an object is, to fix the position of our eye relative to it; which being once fixed, only *one* image or figure could possibly be impressed on the mind. There must, therefore, be only *one fixed invariable natural* plane, intersecting the rays of vision in the same manner under all circumstances and in all cases; and if this were transposed into a sensible, tangible plane, such as a picture, &c., no alteration would take place in the image seen. Now he would prove, by a small diagram, this natural plane to be, as in Mr. Parsey's system, at *right angles to the axis of vision* or centre of the system of rays, which is always in the centre of the object viewed—for in this way only can we obtain the same result in all cases; and as it would be obvious that by the usual system it was possible to obtain *two or more* representations of the original object with *the same given data*, it must be manifest that it is erroneous, and cannot be depended on as affording satisfactory results. After Mr. Hance had concluded his remarks, which were listened to with much interest, an animated discussion took place; and it was the unanimous opinion of the meeting, "That Mr. Parsey's mode of finding the plane of delineation is the *correct* one."—*Manchester Guardian.*

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Eighth Meeting, held at Newcastle-upon-Tyne.

AUGUST, 1838.

Another meeting of the Association has taken place; and although it has been more successful than its predecessors in the number of its attendants, it has undoubtedly proved less interesting in its scientific results. Much, however, cannot be expected, for it is not by accumulating philosophers that we shall be able to extract the quintessence of science. These meetings generally prove little more than travelling shows, for exhibiting the lions of the intellectual world.

In the Mechanical Section, which is our more appropriate sphere, very little occurred beyond the reading of papers, the best of which might just as well have been published long since in some of the scientific periodicals, instead of bottling them up for a twelvemonth. Dr. Lardner distinguished himself on this, as on previous occasions. The year before last he proved beyond doubt, to all the novices in England, the impossibility of Atlantic steam navigation, and the country is indebted to *him* for having caused considerable impediment to its progress. However, the enterprize of the "Great Western" people having shown the Doctor's error, he felt himself called upon to prove that he was still in the right. We have heard of doctors apologizing for the death of their patients, but never before for their recovery. As the worthy philosopher could not now persist in the absolute impracticability of the undertaking, he has endeavoured, after the Quaker maxim, of 'give a dog a bad name,' to knock it on the head by asserting that it can never pay. We shall not combat this assertion at present, but leave the Doctor to do it next year, as he doubtless will try to do. We shall wait patiently for his next antic, and shall feel happy when he has got out of the slough of animal magnetism, to hear him come forward next year with proofs of the truth of that piece of quackery.

It would have shown a culpable degree of negligence in any other man, that the most important grant ever made to the Mechanical Section—that for determining railway constants—has not been made use of. We call this culpable, because in the present infant state of railway science, every month that is lost in obtaining data is of more importance than years in its subsequent progress. It is not the mere paltry amount of money that we regard, but it is the extent of capital ultimately affected by the results of these experiments; for, as they will certainly produce more accurate data, so they must most essentially influence every railway, whether in contemplation or in progress. We know the loss of capital incurred by the Liverpool and Manchester and the Birmingham Railways, and the doubts existing at present with regard to the plan of the Great Western Railway, would have induced any well-thinking man to have pressed the determination of this question, rather than to have lost time. Dr. Lardner, however, thought otherwise, and instead of producing a report, amused the section by informing them how he intended to do what he had not done.

He amused the section with another pretty toy, for registering the operations of steam engines, which was to do a great number of things, but not to tell the distance to New York, which had already been published in the Monthly Chronicle.

The only discussion of any utility was that on the gauge of rails, and we regret that it was suddenly stopped by the president, and not allowed to be resumed. The section could find time to hear papers, that had been published previously or read at the last year's meeting, or scramble through the titles of others like the third reading of an Act of Parliament, but they had no time for an object in which millions of capital are interested. The calibre of these philosophers' minds was more appropriately employed in investigating important objects, and they had no time to devote to useful purposes. One of the favoured children of philosophy delighted them by letting them rummage an improved writing table, which had this unique advantage, that all the drawers could have their locks picked at the same time. Another philosopher occupied the time of the meeting, by explaining an apparatus for cooking by gas!

The ironmasters, who made such a distinguished figure last year, by their enlightened opposition to the experiments on iron, did not make their appearance at this meeting, doubtless to the loss of much scientific knowledge.

Although, considered on the whole, the local preaching of the Association is productive of no very powerful results to science, as in their itinerant circuits they judge and condemn nobody but themselves; yet their ambulatory meetings in their course over the country, offer good opportunities for examining and discussing the merits of the different lines of railway. Newcastle, almost the father land of railways, possesses particular advantages for engineers; as, independently of the fine school of study afforded by the numerous tramroads and railways, it is one of the great seats of the manufacture of locomotive and marine engines.

With regard to architecture, and all departments of art, they are excluded from the operations of the Association; but why they should be so, there is certainly no reason either in the constitution of the Society, or in the relation of these objects to the other pursuits of science. Architecture requires an extensive knowledge of the mathematical and philosophical sciences, and we can conceive no argument for the admission of many papers read at the meeting, to the exclusion of the votaries of that art, which, as well in the pyramids of Egypt as in the latest of its works, has elevated some of the finest monuments of practical science. It might not be unproductive of advantage to give young architects an opportunity of examining provincial works during their holydays at these Saturnalia of Minerva. In most of the cities of meeting, and particularly at Oxford, Cambridge, and Dublin, are

many fine edifices; and Newcastle has recently exhibited considerable improvement in this respect.

Another improvement which might be introduced into the Association would be either to form a section for arts, manufactures, public works, colonies, and commerce, or else make them a part of the statistical section. With regard to public works particularly, it would effect great good to afford facilities for their study, and for the centralization of information on the subject. It is only recently that the attention of individuals has been directed to forming a correct body of practice of canals, and there are plenty of other branches which would benefit essentially by their more enlightened study.

(From the Athenæum.)

Section G.—Mechanical Science.

On a new Day and Night Telegraph, by Joseph Garnett.

The paper on this subject was accompanied by a model, to exhibit the construction and method of working of the telegraph, which it is proposed should consist of two ladders, about forty-one feet long, framed together at about twenty-four inches asunder at the bottom, and twenty at the top, so as to constitute the frame for the machinery. There are two arms, one at the top, the other about midway up the frame-work, counterpoised by weights, and worked by machinery, consisting of eight bevel mitre wheels. At the bottom of the frame work is a dial plate, with a pointer, and the workman, in setting the pointer, brings the arm of the telegraph into the required corresponding position. The paper proceeded to describe the mechanical adjustments, and was accompanied by tables of the day and night signals, each of which contains fifty-six variations of the arms. The night signals are made by covering the lamps in a particular order. For instance, two vertical lamps covered designate twenty—two horizontal ones covered thirty—and so on.

On Isometrical Drawing, by Thomas Sopwith.

The object of the author in this communication was, to call attention to certain instruments, by which the operation of isometrical projection is greatly facilitated. These are a set of triangular rulers, drawing paper, with the lines and ellipses described upon it, and the isograph, which consists of a number of rulers, made of brass or ivory, the fiducial edge of each being an inch apart, and parallel to each other. The triangular rulers are serviceable for making projections of the angles of isometrical cubes, and the isograph is peculiarly adapted for copying maps. Some specimens of maps so copied were exhibited. Mr. Sopwith gave a detailed account of the way in which he used the above instruments for the purposes of isometrical projection.

On the Power of Economizing and Regulating Heat for Domestic Purposes, by George Webb Hall.

The author insisted on the necessity of having the backs of the fire-places vertical, and the apertures of the chimneys as contracted as possible; and he described the results of his experiments. One principle to be universally attended to in close fire-places is, that the burning fuel be surrounded by a substance retentive of heat, and capable of radiating it back upon the fire itself. This is attained by covering the fire itself with a species of fire-brick, and only allowing a very small aperture for the escape of the heat thus forced off at the highest degree attainable, then to be economized by close confinement and regulation. The economy of heat when attained, consists in conducting the hot air through long and horizontal flues, so as to counteract as much as possible its tendency to ascend, which tendency is exactly proportional to the temperature. The author illustrated the preceding paper by details of the arrangements which he had adopted, and alluded especially to the researches of Rumford on this subject.

Notices on the Resistance of Water, by John Scott Russell.

Mr. Russell stated, that the observations he had to offer might be considered as a sequel to what had been given at the preceding meetings of the Association. He and Sir John Robison had been constituted a committee to prosecute the investigation of the motion of waves, and other problems in hydrodynamics, the results of which would be given in the Physical Section. But, as they went on, they had met with some results of great value to the practical man; of these, he now proposed to give a brief account to the Section. The general problem was the resistance of a fluid to a floating solid. Now, this is a department of science, of which we are avowedly ignorant; so much so, that some of our best vessels are acknowledged to be constructed by the rule of thumb, as it is termed—that is, by knowledge gained from a repeated series of trials and errors, and not on any fixed scientific principles. It had been ascertained in previous investigations, that the action of a solid on the water is very different from the action of fluid when impinging on a solid. These actions had formerly been considered the same. The solid causes an elevation; the elevation puts the water in motion. Thus, the question of resistance resolves itself into that of the motion of waves. Waves are of various kinds. The laws of the great primary wave had been laid down in previous communications. Its velocity depends simply on the depth of the fluid. The old law of resistance, as the square of the velocity, is too small so long as the velocity of the solid is less than that of the wave, but too great so soon as the velocity of the solid becomes greater than that of the wave.—Mr. Russell then detailed some experiments which had led to the above law, and from which it appeared that the form of the vessel of least resistance depends as well on the velocity with which it is to move as on the velocity of the wave; also that the form which is best for moving with a velocity less than the velocity of the wave, may be worst for moving with a velocity greater than that of the wave. The consideration of the laws of this wave reconcile many of the discrepancies in experiments on this subject. Mr. Russell then proceeded to describe some remarkable facts, which they had observed on the motion of the particles constituting this wave; the particles had a vertical and a horizontal motion, and the extent of the motion depended on the force of the wave. Another remarkable result is, that the ordinates of the vessel should correspond with the ordinates of the wave; a form so constructed would separate the water without any apparent elevation or white ripple, which was common to all other forms. The form is that which belongs to the wave, which is to move with the particular velocity of the vessel.

The accompanying diagrams will serve to convey a more distinct idea of the nature of the motion of the particles of the water.

Fig. 1.

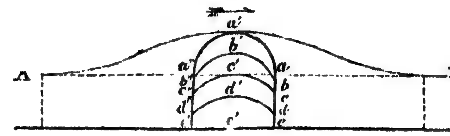


Fig. 2.

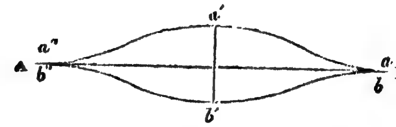

Fig. 1 shows the form of the wave, and the lines of translation of the particles during the transit; A a' B the line of the wave; $a\ a'\ a''$, $b\ b'\ b''$ $c\ c'\ c''$ &c., lines of translation of the particles during the transit.

Fig. 2 shows how the lines of a vessel are to be formed so as to produce a displacement analogous to the displacement of the wave, and so move through the fluid with the least resistance.

On the Principles of Oblique Bridges, by Peter Nicholson.

The oblique arch, an invention of comparatively recent date, has been rendered necessary by the general adoption of railways, and by the necessity which exists for their being carried forward in lines as direct as possible. The theory of this arch is attended with some difficulty, and the author lays down in this paper the principle by which the engineer should be guided. Five of the faces of each stone are to be prepared in such a manner that four of them recede from the fifth, and when the stones are arranged in courses, the surfaces of the fifth face form one continued cylindric surface, which is the intrados, and the other four faces form the beds and ends of the stones in which they join each other. In every course two of the opposite courses of the first stone, two of the opposite surfaces of the second stone, and so on, form two continued services throughout the whole length of each course, and the edge of each of these continued surfaces in the intrados will be a spiral line. If a straight line be drawn through any point in one of the spiral lines perpendicular to the axis of the cylinder, the straight line will coincide with that continued surface which is a bed of that course, and the straight line thus drawn will be a tangent to the curved surface of the cylinder at that point in the spiral line; the straight line then drawn will be perpendicular to another straight line, which is a tangent to the spiral line at that point. The intrados being developed, the spiral lines which form the edges of the courses will be parallel and their distances equal, and the spiral lines which are the edges of the ends of the stones will be developed in straight lines perpendicular to those lines which are the developments of the spirals of the edges of the courses. From these principles a simple geometrical construction may be deduced, such as the workman can readily use. To construct an arch on the above principle it is only necessary to know the angle of obliquity of the acute angled pier, the width of the arch within its abutments, the height of the intrados above the level of the springing, the perpendicular distance between the planes and the two faces, and the number of arch stones in each elevation. The author then detailed some examples illustrative of this method.

Remarks on the Material and Mechanical Construction of Steam Boilers, by W Greener.

Mr. Greener is of opinion that the accidents which happen to steam boilers are principally due to defect in the material of which they are constructed; and he details several experiments made on slips of iron cut from plates of different quality. He found that slips cut latitudinally from a plate bore less by 30 per cent. than slips of the same dimensions cut longitudinally; in some cases the difference was much greater. He also had immersed plates in a mixture of sulphuric acid and water, and found that the injury done in twenty-four hours varied from 6½ to 15 per cent. of the original strength. Many boilers will stand so long as the form remains perfect; but should any part, as the crown of the arch, in cylindrical boilers, collapse, an accident is inevitable.

On a Substitute for the Forcing Pump in supplying Steam Boilers, &c., by Mr. Maule

It was a hollow cock having an orifice, which, being uppermost, the plug became filled with the liquid, and then, being turned half round by the motion of the piston, the liquid could run into the vessel below.

Sir John Robison explained a *model of the bucket of a pump in use i*

Sweden, the peculiar feature of which was, that the pressure of the sides of the bucket outwards against the pipe is exactly proportional to the load to be raised. This bucket is peculiarly applicable for raising foul water.

A New Rotatory Steam-Engine, by S. Rowley.

The inventor being absent, Mr. Evans undertook to bring this before the Section; and having pointed out the construction, stated that the only novelty in this consisted in the eccentric being on the inside. Many present condemned the rotatory engine as mechanically impracticable. Many of the most talented mechanics of this country had given up the attempt after repeated trials. It was argued, that no theoretical advantage can be gained by it; and that though there might be some circumstances under which economy of space and first cost were of such importance that the most expensive wear and tear could be borne, yet no prudent man would purchase an engine which might ruin him in the repairs. It is not sufficient to have a good theory; the powers of mechanical construction must be considered; many inventions which thirty years ago might have been lost, because they were antecedent to the march of the mechanical art, would now, in the wonderfully advanced state of this art, be generally introduced.

Report on Railway Constants, by Dr. Lardner.

Dr. Lardner stated, that at the last meeting of the Association a sum of money had been voted for the purpose of ascertaining certain railway constants,—that is, the force of traction on a level plane; the resistance due to friction, to curves, to the atmosphere; how the force of the wheels and the carriages influenced the motion. He then explained the causes which had prevented the experiments being made, and that, consequently, he had nothing to report as experimentally determined on the above subject; but that he had that instant received a set of experiments on the above subjects, made, at his request, by Mr. Woods, the resident engineer of the Liverpool and Manchester Railway, a young man whose excessive modesty alone prevented his occupying the position which his talents could claim. Some of these results, especially those relating to the effect of the resistance of the atmosphere, he then alluded to. He then described the various methods which had been proposed for the determination of the constants in question. These differed in no respect from the statements which were made last year at Liverpool. He also described a dynamometer, by which the traction might be measured with considerable accuracy; and concluded, by adverting to the great experiment which was now trying on the Great Western Railway, with respect to the gauge of seven feet instead of four feet eight inches.

An improved Method of Constructing Railways, by J. Price.

This method consists in fixing rails on a continuous stone base, a groove having been made in the stone to receive a flange or projection of the lower side of the rail. The stones and rails are to break joint with each other, and the chair by which the rails are to be secured is to be made fast to the rail by a bolt, not rivetted, but slipped in. The chair is to be sunk until the top is level with the top of the stone, and fastened to it by two small wooden pins. Any sinking of the road is to be obviated by driving wedges of wood underneath the stone until it is raised to the required height. The chairs are to be fixed at about 4 feet apart, and to weigh, if of malleable iron, 14 pounds, but if of cast iron, 20 pounds: the rail to weigh 50 pounds per yard.

On the Construction of a Railway with Cast-Iron Sleepers, as a substitute for Stone Blocks, and with continuous Timber Bearing, by T. Motley.

The cast-iron sleepers, which are wedge-shaped, and hollow, having all their sides inclined inwards towards the under side, are to be laid transversely, and the timber is to pass longitudinally through the centre, and to be secured by wedges of iron and wood. The sleepers are to be six inches apart, and the timber of such a thickness as to prevent any perceptible deflexion betwixt the rails. The road is to be ballasted up to the top of the sleeper, and the timber to stand out sufficiently, and to have any approved rail laid upon it.

Mr. Stephenson considered the plan too expensive.—Mr. Donkin observed that a certain portion of elasticity was beneficial.—Mr. Vignolles said it appeared to him to be Mr. Reynolds's plan cut in pieces.

Machine for raising Water by an Hydraulic Belt, by Mr. Hall.

In this machine, an endless double woollen band, passing over a roller at the surface of the earth, or at the level to which the water is to be raised, and under a roller at the lower level, or in the water, is driven with a velocity of not less than 1000 feet per minute. The water contained betwixt the two surfaces of the band is carried up on one side and discharged at the top roller by the pressure of the band on the roller, and by centrifugal force. This method has been in practice for some time in raising water from a well 140 feet deep in Portman Market, and produces an effect equal to 75 per cent. of the power expended, which is 15 per cent. above that of ordinary pumps. This method would be exceedingly convenient in deep shafts, as the only limit is the length of the band, and many different lifts may be provided.

Mr. Hawkins had seen a machine very similar, fifty years ago.—Mr. Donkin, without entering on the question of originality, stated that he had seen a machine of this description working with a beneficial effect of 75 per cent., the beneficial effect of ordinary pumps being about 60 per cent.

On Cliff's Dry Gas Meter, by Mr. Samuda.

This instrument consists of a pulse glass, that is, two thin glass globes united by a tube. These globes are partially filled with alcohol, and hermetically sealed when all the air is expelled from their interior. In this state, the application of a very slight degree of heat to one of the globes will cause the alcohol to rise into the other. The pulse glass is fixed on an axis, having a balance weight projected from it, and the axis works in bearings on the sides of a chamber through which the gas to be measured is made to pass the gasometer in two currents, one of which is heated and the other cold. The hot gas is made to enter opposite to, and to blow upon the top globe of the pulse glass, while the cold gas blows upon the other. The difference of temperature thus established between the globes causes the alcohol to rise into the upper one, and the glass turns over on its axis, thus varying its position, and bringing the full globe opposite to the hot stream of gas. This stream, with the assistance of the cold gas, which condenses the vapour in the top globe, repeats the operation, and the speed at which the globes oscillate will be precisely in proportion to the quantity of gas which has been blown upon them, provided a uniform difference of temperature is always maintained between the two streams of gas. The difference of temperature is established and rendered uniform by a small flame of gas, which heats a chamber through which the lower current of gas has to pass, and the arrangements for securing an equality in the difference of temperature are very ingenious. The instrument is first tested by making a given quantity of gas pass through it, and observing the number of oscillations of the pulse glass. This once established, the instrument registers the quantity passed with inconceivable accuracy.

Considerable discussion ensued, during which many objections were raised, to which Mr. Samuda replied.—Mr. Liddell observed, during the progress of the discussion, that a flame consuming one-fifth of a cubic foot of gas per hour would burn in a chamber, and not be liable to be extinguished by the opening and shutting of doors; and that if due precaution were used, a flame might be preserved with a consumption only of one-eighth or one-tenth of a foot per hour.

On the construction of Geological Models, by Thomas Sopwith.

Mr. Sopwith lays down a method by which the commonest workman can make geological models, showing not only the position and thickness of the strata in a vertical section, but the actual surfaces and imbedding of the strata lying in different planes; so that one tray of the model being taken from above the other, we may consider that we have the stratum in minature, with every undulation and indentation upon it. There was exhibited a model of the Forest of Dean, constructed in the following manner. The plan of the district was divided by lines crossing each other at right angles, and at the distance of a mile from each other. A vertical section was then prepared corresponding with each of these lines. These sections were drawn upon thin pieces of wood in the ordinary manner of a vertical geological section, and the several pieces of wood were then united by being half-lapped together, forming a skeleton model of vertical sections. After being thus united, the several sections were taken separately, and cut into as many portions as were required to illustrate the successive layers of strata; the intersection of each of these portions having been first marked by a number at the several corners. After each section has been divided into its several parts, these respective portions are again united, and formed the exterior boundary of a square mile of rocks. The interior of this is filled with wood, and carved so as to coincide with the sections. Any intermediate portion can be fitted in with great exactness, first by a thin or skeleton section, and afterwards by wood, which any workman can carve with the most exact accuracy as quickly and as surely as any ordinary mechanical operation; and thus at once a connexion between the most complicated section and the art of a common workman is accomplished. The outline of the surface, and the general contour of the country is obtained, partly by means of the skeleton sections, and partly by the use of a gauge, or graduated pencil, sliding in a frame, in the same manner as practised by sculptors in transferring the dimensions of a cast to a block of marble.

Description of an improved Levelling Stave, for Subterraneous as well as Surface Levelling, by Thomas Sopwith.

The method of reading the figures of the stave itself, instead of the sliding vane, as adopted by most experienced engineers and surveyors, is used in Mr. Sopwith's improved staves. The figures are engraved on copper-plate, on an enlarged scale, so as to contract in drying to their proper length, which is fixed by a very accurate gauge. The arrangement of the scale is that of feet, divided into hundredth parts, alternately black and white; and in the form of the figures, clearness and distinct vision at a distance are chiefly aimed at. Mr. Sopwith's improvement consists in the mechanical arrangement of the slides, which are held in any fixed position by means of a catch or spring. The stave for mining purposes has also an entirely new arrangement. It has a glass shield or cover to protect the face of it from wet and dirt; and is hinged, so as to work in any seam of from three to five feet; but the principle may be adopted for any greater or less extent.

On a Suspension Bridge over the Avon, Twerton, by T. Motley.

The peculiar feature of this bridge, is, that each chain is attached to the roadway, and the suspending bars are carried up through each chain above it. The length of the bridge is 230 feet, the breadth 14 feet, and the cost, including the towers and land abutments, under £2,400. This bridge is superior to the common suspension bridge, in that it is more firm, and experiences much less friction, owing to the absence of vibration.—*Vide Journal, No. 10, page 253.*

Models were exhibited and partially explained of a suspension bridge of wire, erected over the river Avon, near Bath, by Mr. Dredge. The bridge is upwards of 230 feet in length, the breadth of the roadway is fourteen feet, and the whole, including land abutments, &c., was completed for less then £2,400.

A method of Pumping Water from Leaky Vessels at Sea, by Mr. Dalziell.

The machine is worked with a piston, the motion of the vessel being given by the stream when the vessel is sailing, to paddle wheels on the sides.

An instrument for Measuring Timber, by J. Smith.
A peculiar Combination for the Wheel Work of a Crane, by W. Horner.
A peculiar form of Steam Engine Boiler, in use at the Glass Works at Gateshead, by J. Price.

The principal advantages of this boiler were said to be, the impossibility of collapsing, the rapidity with which it generates steam, and the small consumption of fuel.

Professor Willis described his instrument, called the *Odontograph* (vide Journal, No. 9, page 229). He also described the construction and use of some scales of measurement, invented by Mr. Holtzapffell (vide Journal, No. 8, page 186).

On Improvements in Ship Building, by Mr. Lang.

Mr. Lang described and exhibited some models, illustrative of the safety keel, which had been introduced with great success; and mentioned instances in which vessels fitted with these keels had struck and come off without sustaining material injury. He then entered into some details respecting the proper construction of merchantmen, and exhibited some models of the bottoms of merchantmen. He also exhibited a method of securing a round headed rudder, and a model of a tube scuttle to admit light between decks, and which had been used with great success.

On the use of Wire Ropes in deep Mines, by Count Augustus Breunner.

There had been introduced into the silver mines of the Hartz Mountains, about seven years ago, ropes composed of twisted iron wire, as a substitute for the flat ropes previously in use. Since that time they have been adopted throughout the mines of Hungary and most of those in the Austrian dominions, to the almost total exclusion of flat and round ropes made of hemp. These iron ropes are of equal strength with a hempen rope of four times the weight. One has been in use upwards of two years without any perceptible wear, whereas a flat rope performing similar work would not have lasted much more than a single year. The diameter of the largest rope in ordinary use in the deepest mines of Austria, is one inch and a half. This rope is composed of iron wires, each *two* lines in diameter; *five* of these are braided together into strands, and *three* of these strands are twisted tightly into a rope. Great care is requisite in making the rope that the ends of the wires be set deep in the interior of the rope, and that no two ends meet near the same part. The strength of these ropes is little less than that of a solid iron bar of the same diameter. The usual weight lifted is 1000lb. The rope on leaving the shaft must be received on a cylinder of not less than eight feet diameter, and be kept well coated with tar. There is a saving of about one-third of the power in one case mentioned, for *four* horses with a wire rope are doing the same work as *six* horses with a flat rope. It was suggested by the distinguished foreigner, that the introduction of iron ropes for the flat ropes in our deep mines and coal-pits would be attended with the same, if not greater advantages, than has attended their introduction into the mines of the Austrian dominions.

On Steam Navigation and a self-recording Steam Journal, by Dr. Lardner.

Dr. Lardner said, no one could be more deeply impressed with the importance of the observations which had just fallen from the President than he was; and there was not any member of the Association more willing to admit the error into which he had fallen than he should be found to be. It was, however, a matter of no real importance how far any opinion which he might have formerly expressed on extended steam navigation was right or wrong, except so far as it had been made a personal question. The subject was first broached at the Bristol meeting of the British Association, when a discussion arose upon it, and he then remarked, that it was a great experiment which had not yet been attended with any satisfactory result. Unquestionably, he did express a discouraging or unfavourable opinion as far as regarded the probability of ever maintaining an unbroken intercourse by means of steam navigation between Great Britain and New York. But he had been charged with declaring that the transit by steam navigation between Great Britain and New York was a physical impossibility. He never had given expression to such a statement, or to anything equivalent to it; and, as a proof, he read a passage from the article on Steam Navigation, which appeared in the *Edinburgh Review* soon after the Bristol meeting, and which expressed the opinions he then held. He must, however, now acknowledge that the success of the Great Western steam-ship had shaken the opinions he then entertained, and should the same success continue throughout the various seasons of the year, he would be the first to come forward and acknowledge himself completely in error. Dr. Lardner then proceeded to the proper subject before the Section, namely, the duty of marine engines, for ascertaining which a sum of money had been last year granted by the Association. He had been in communication with many steam navigation companies, and found that it would be a hopeless task to attempt to get the men on board the vessels to register with accuracy all the various facts required to be registered. He had consequently considered how this might be done by machinery, and the result was the construction of the instrument before them, and which he termed a steam journal (vide Journal, No. 7, page 167).

On Steam Navigation, by Mr. J. S. Russell.

The object of this communication was to endeavour to point out the means which might be attempted, with the greatest probability of success, for improving steam navigation. It was of importance to consider whether they should look to some new, and as yet untried method, or to improved combinations of the means already in common use. The latter was the better course; and these improvements might be in the vessel itself, in the machinery, or in the nature and application of the fuel. Mr. Russell then adverted to the fallacy of maintaining, as some persons did, that the form of the vessel was alone to be considered, while others held the directly contrary opinion, that an increase of power alone was to be considered. Mr. Russell, however, considered, that in the present state of steam navigation, the opinions of the former were most to be attended to. With reference to these questions, two great experiments had, he said, been made. Two fifty horse power engines had been taken out of a vessel, and two sixty horse power engines put in their place. When the propelling power was two fifties, the velocity of the vessel was ten miles and three quarters per hour. When it was two sixties, the velocity with which the vessel moved was ten miles and six-tenths per hour. Here then was an increase of power, a greater expenditure of fuel, and the increase of the velocity was only three-tenths of a mile. Another experiment was made on two vessels, one of 450 tons, and the other of 500 tons burthen. The larger vessel was propelled by two engines of 300 horse power, and the smaller one by two of 150 horse power. The larger vessel, with the double power, proceeded at the rate of nine miles and a half an hour, whilst the smaller one moved at the rate of nine miles and a quarter an hour. This instance he thought extremely satisfactory; the smaller vessel had the proper form that a vessel should have, and the larger one had not. He was, therefore, of opinion, that the form of the vessel was the direction in which we should look for improvement. Indeed, he thought it probable, that ere long we should have vessels of double the length, for a given breadth, that they at present generally are. The objection to an increased length, from the danger of what is called "breaking the back," might be in a great measure removed by a proper system of diagonal framing. Another important consideration is, that the linear dimensions of a vessel being doubled, the capacity is increased eightfold, but the increase in the resistance need not be more than twofold.

Mr. Russell at a subsequent meeting recalled attention to the following points—that, by doubling the three dimensions of the vessel, eight times the space, at an expense of only double the power, might be obtained—that the form of the vessel must be especially attended to—and that the objections on account of sharpness, which were applicable to sailing vessels, do not apply to steam vessels. He insisted on the propriety of making steamers sharp. Nautical men had great objections to extremely sharp vessels, and preferred full bows. He did not wish to do away with the fulness, but to leave the fulness in its proper part, and add a sharp prow to full bows. By this means, great advantages might be obtained in the proper stowage of the cargo, and proportioning of the load. Breadth and fulness in the centre are absolutely indispensable, and this can only be obtained by lengthening out the extremities. Mr. Russell next proceeded to the subject of power, especially with reference to that of the boilers, which depends on the surface. The points especially to be attended to are, extent of surface, thickness and quality of material, and modes of strengthening. Iron boilers, with copper tubes, possessed considerable advantages; the form of boilers is of little consequence, provided extent of surface be obtained.

On Riveting Boiler Plates by Machinery, by W. Fairbairne.

Mr. Fairbairne described the machinery which he had invented for making boilers. By this machine two men and two boys can fix eight rivets three-quarter inch diameter per minute, or nearly 500 per hour, whereas, by the ordinary operation, with an additional man, not more than forty can be inserted; thus the advantage is as about 120 to one, besides the saving of one man. By this machine an ordinary locomotive boiler, ten feet six inches by one foot diameter, can be riveted, and the plates fitted in *four* hours; whereas the time required, besides extra hands, without this machine, would be *twenty* hours. The work is also much superior. The rivets being hot, the holes are completely filled, and the rivet by its contraction draws the plates so closely together, that the joints are perfect. On testing a high pressure boiler made by this machine to 200lbs. on the square inch, there was no leakage; but in a boiler made by hand, very many of the rivets would be found to leak.

On the Construction of Timber Viaducts, by B. Green.

The timber viaducts constructed by Mr. Green, on several lines of railway, consist of arches on stone piers. These arches consist of three ribs, and every rib is put together with three-inch deck deals, in length of from twenty to forty-five feet, and two of the deals in width. The first course is composed of two whole deals in width, and the next of one whole and two half deals, and so on alternately until the rib is formed. Each rib consists of sixteen deals in height or thickness, their ends making joints, so that no two of the horizontal or radiating joints shall come together. The three ribs are connected together by diagonal braces and iron bolts; the spandrells are strutted in a peculiar manner: the whole of the timber was subjected to Kyan's process, and between every deal is a layer of brown paper dipped in tar. The same principle of constructing arches of iron by laminated plates, has been adopted by Mr. Green. Wrought iron bars from one and a half to four inches square (according to the span of the arch), from fifteen to twenty-five feet long, grooved on the under and tongued on the upper side, are laid one over the other and bent over a centre, until the rib is formed. The iron bars are bound together at intervals of from four to six feet apart, with iron straps and keys round the rib. The spandrells are fitted with iron struts. A considerable saving of expense and great lightness, as compared with stone or ordinary iron bridges, may thus be attained.

On an improved method of Working the Valves of a Locomotive Engine.

Professor Willis described the method recently introduced by Mr. Hawthorn, for working the valves of a locomotive without the usual eccentrics. The motion is derived at once from the connecting rod, by means of a pin placed at the centre of the connecting rod, and giving to a frame a reciprocating

motion in a vertical direction, at every revolution of the crank. To this frame are attached arms, by which motion is communicated to the slides. It is necessary that the slide should be open for the admission of the steam into the cylinder, a little *before* the piston has completed the stroke; this, which is technically termed the *lead* of the slide, must be provided for with great care, so as to correspond with the various speeds of the piston; this arrangement cannot be made where eccentrics are used without considerable difficulty, but this is provided for in Mr. Hawthorn's method, by simply changing the angle at which the frame is set—an operation which can be performed by adjusting a screw.

On Methods of Filtering Water, by J. T. Hawkins.

In this paper the author detailed the various essentials for a durable and simple filter for obtaining pure water. The charcoal must be perfectly well burnt, and kept from exposure to the atmosphere; a test of good charcoal is, that when pulverized it sinks rapidly in water. The charcoal must be supported on an indestructible material, as a plate of burnt clay perforated with holes. The filter may consist of a common gardenpot, or similar vessel with holes at the bottom. The lower part may be filled with round pebbles, then some smaller pebbles, then some coarse sand, and finally a stratum of pounded charcoal, of about three or four inches in thickness. It is a great mistake to put any material, as sand, above the charcoal, with the view of arresting the grosser particles of impurity, as the sand will quickly stop up and be impervious to water. A filter thus prepared will render water perfectly clear and sweet for many years.

On the Effect of Sea and River Water on Iron, by Mr. R. Mallet.

Mr. Mallet stated, that he and Professor E. Davy had, at the request of the Chemical Section, been associated in a series of experiments on the action of sea and river water on iron. They had come to results of great importance to the civil engineer, some of which he would mention. They found that pure oxygen and pure water are both neutral bodies in regard to iron, and only act on it together; that the larger the quantity of uncombined or suspended carbon in cast iron, the more is it acted on by these agents, so much so, that soft Scotch or Irish cast iron may be used to protect grey or chilled cast iron from all corrosion. With respect to the protection of iron by electro-chemical agency, zinc will only protect iron for a time; the oxide of zinc becomes tranferred to the surface of the iron, when all protection is at end. Brass, as proposed by Mr. Hartley, will not protect iron, and he showed some specimens brought from the Liverpool Docks, in which the corrosion had clearly been promoted by the adoption of this method.

The Secretary read the following titles of communications received:—Mr. Reed, *On an improved Safety Hook and Bow for Coal Pits.* Mr. Glynn, *On the Waterworks of Newcastle.* Mr. Wake, *On a new Paddle Wheel.* Sir Charles Monteith, Bart., *On a new Tram-road*; also, *On an improved Kitchen Grate.* Mr. Fourness, *On Coal Mine Ventilation.* Mr. Dobson, *On a method of making Bricks of every required Colour.*

Durham Junction Railway.—The committee attended the procession for opening the railway, on Friday, August 31st. The object of most interest was the "*Victoria Bridge*"—the entire length of which is 270 yards, and its width, within the parapet walls, 21 feet. There is a double line of railway over the bridge, with a flagged causeway for foot passengers. According to the Newcastle Journal, the arch over the river Wear is 160 feet span; from the foundation of the pier to the spring of this arch is 72 feet; from the springing to the crown of the arch the distance is also 72 feet; and from the crown of the arch to the parapet wall, is 13 feet, making in all 157 feet. From this, to obtain the height for the ordinary water level, we must deduct the solid masonry buried beneath the waves, which makes the observable walling 130 feet. This is considerably higher than the celebrated Sunderland Bridge, and (as Mr. Ingham, the chairman at the banquet observed), taken as regards *height* and *span*, is the largest arch in Europe. True it is that the arch of the bridge over the river Dee, near the city of Chester, is wider, and the Spanish bridge at Alcantara, near Lisbon, is more lofty; but, taking into consideration the united difficulties of extent of span, and height from the water level, the "Victoria Bridge" must stand unrivalled.

REVIEWS.

Continued from page 336.

A Series of Lithographic Drawings on the London and Birmingham Railway, by John C. Bourne; *with Topographical and Descriptive Accounts of the Origin, Progress, and general Execution of that great National Work, by* John Britton, F.S.A., &c. Part 1, *with Eight Drawings.*

We have received several specimen-plates of this highly interesting publication, which are executed in the first style of lithographic art. Each drawing portrays the construction of the works on different parts of the railway, and at the same time it shows the manner of executing them, the artist having very happily hit upon each view at the identical moment of greatest interest; for instance, in the sketch of the entrance to the Watford tunnel, the men appear to be engaged in fixing an iron brestsummer of great length over the archway, which we presume is for the purpose of tying in the stone-work, to prevent the superincumbent weight forcing it out. This mode of construction might escape the vigilant eye of the most skilful engineer, if he had not been present at the time of executing the work. Another drawing shows the method of forming embankments from side-cuttings; and another, the construction of the iron bridge over the Regent's Canal, Camden Town. We shall hereafter notice this work more minutely; in the mean time we hope the first part, containing eight drawings, will meet with that encouragement from all parties connected with railways, as to induce the artist to continue his labour on some other similar undertaking.

Plan of Trafalgar Square, and Site of the Ground for the proposed Nelson Monument, measured and drawn by H. Courtney, Surveyor.

This plan is indispensable to every architect and artist who intend to compete for the premium. We very cheerfully recommend it to them, as likely to save both their time and expense. A section of the levels, both longitudinally and transversely across the square, is also given; likewise the height of the portico to the National Gallery.

Suggested Site for the Equestrian Statue of his Grace the Duke of Wellington.

We have received a lithographic drawing of a design for the Wellington Testimonial, by Mr. Wallace, which is fully explained in the description accompanying it, and which we transcribe to our columns for the information of our architectural friends.

It is manifest to most persons of taste and observation, that in the formation of the entrance to St. James's Park from Waterloo Place, an opportunity such as does not often present itself, of producing an effect truly classical and imposing, has been entirely overlooked. With such elements as a flight of steps 70 feet in length, and a rise in level of 15, something very different from the present bald and insipid appearance must have been produced, had not the carrying into effect the afterthought of an entrance here been governed by considerations of utility and economy alone. The situation is admirably adapted for a portal, in the style of the Athenian propylea: and though the erection of the Duke of York's Column has for ever barred the erection of such a feature, much may still be done to ennoble and dignify the place, and render it more worthy of the name it bears, or should bear, "the Waterloo Gate." The public voice seems generally to condemn the idea of placing the equestrian statue of the Duke of Wellington across the arch into the Green Park, as a solecism in taste; and another situation, it is presumed, will be sought for.

The centre of the opening for the Waterloo steps, on the Park side, is one which, from its peculiar nature, is better adapted, perhaps, for a pedestal and statue of heroic dimensions, than any other that could be pointed out. Why should not the proposed "Testimonial" be here? The proximity of the Duke of York's Column on the higher level is any thing but an objection. So far from injuring, the two objects would admirably harmonize with, and assist each other, both with regard to grouping and association, and with the aid of a few suitable accessories, the entire locale would assume a majestic and trophied character, indicative of military glory and achievement.

An attempt has been made to illustrate these ideas in the accompanying lithograph. The cornice or surbase of the pedestal on which the statue of the Duke is placed, being made to range with that of the column on the upper platform, is at the height of fully 30 feet from the ground, which, with the blocking and plinth over, would dictate a height of something like 20 for the statue, and give a total altitude of about 54—dimensions which, colossal as they are, would seem by no means extravagant, taken in relation to the lofty façades of Carlton Terrace, and the open area of the Park.

It is suggested that the pedestal should be of red granite, polished from the top of the base upwards, the front face having a figure of Victory, in basso relievo, and perhaps other emblems or inscriptions, might be sparingly wrought on the remainining faces. Such a pedestal, it is presumed, would in itself be a majestic and noble object, imposing from its simplicity and magnitude, and not unworthy the renown of the illustrious individual whose effigy it would bear. The dark tint upon the statue implies that it should be of the most noble and least perishable of materials—bronze. The removal of a few adjacent trees (required even under present circumstances) would open up a view of the statue from the Horse Guards and Treasury across the Parade, and with especial reference to the Duke's military career, the glory of which acts as a dissolvent of all political and party feeling, no spot, it is confidently submitted, can be selected more appropriate.

LAW PROCEEDINGS.

DIVERSION OF ROADS BY RAILWAYS.

We understand that the question of how far the Grand Junction Railway proprietors are authorised, by their act of Parliament, to divert roads, is likely to be decided, ere long, in a court of justice. It appears that in the neighbourhood of Perry the proprietors, in their usual cool manner, have stopped up a road, and, instead of making another convenient one, either over or under the railway, they have diverted it a considerable distance, by the side of the railway, into the turnpike road, and absolutely obliged the passengers on a bye-road to pass through a turnpike gate. The surveyor of the roads determined to assert his rights, by passing over the railway. For doing this

he was summoned before Captain Devy. Mr. Swift, solicitor to the company, attended, and the magistrate felt bound to convict in the mitigated penalty of 1*l.* The surveyor was not satisfied with the decision of one magistrate, and crossed the railway again. The case was, a second time, heard by Lord Dartmouth and Captain Devy, and the magistrates both held the opinion that they were bound to convict. The consequence of these two decisions will probably be the indictment of the Grand Junction Railway Company for illegally stopping up an ancient highway. It is a question of much importance to the public, as there are many other cases where the railway company have stopped up roads, much to the annoyance of persons residing in their neighbourhood, and, apparently, without any just right so to do.—*Birmingham Advertiser.*

LAND TAX ON RAILWAYS.

On Tuesday, the 4th ultimo, an important appeal came on for hearing at Hoo Green, before the Commissioners of Land Tax for the Bucklow Hundred; present W. T. Egerton, Esq., M.P., Edward Jeremiah Lloyd, and James Heath Leigh, Esqrs. Mr. Swift, solicitor, Liverpool, on behalf of the Grand Junction Railway Company, appealed against the land tax assessed upon the railway, in the townships of Walton, Duddon, Preston, Moore, Keckwick, Aston, and Acton, amounting altogether to 142*l.* per annum. Mr. Thomas Barker, Northwich, and Mr. Nicholson, of Leeds, appeared on behalf of the townships, to support the assessments; and the question to be decided was, the liability, or the non-liability, of the railway to the land tax at its improved value. After a long and patient hearing, and perusal of several acts of Parliament, and opinions of eminent barristers, the chairman delivered the opinion of the court, and declared the railway liable to be assessed to the said land tax at its improved value.—*Macclesfield Courier.*

RAILWAY COMPENSATION.

TARBUCK *v.* THE BLACKWALL RAILWAY COMPANY.

In the Sheriff's Court, on Saturday, 22nd ultimo, a case was tried which involved a point of considerable interest. The plaintiff claimed the sum of 455*l.*, the value of two houses belonging to him, and the sum of 120*l.*, for the anticipated injury that would be done to two other houses belonging to him, and which would be deteriorated by the works of the railway. The defendents offered 320*l.*, in satisfaction of the former claim, and denied the right of the plaintiff to compensation for any prospective damage. On evidence being tendered to prove the latter claim, Mr. Hill, for the defendants, objected to its being received, on the ground that no action could lie for damages that might accrue in future; in furtherance of this opinion he cited several cases in point. Mr. Jones, for the plaintiff, contended that he had a right to compensation now. The under-sheriff decided that the right to call for damages for an anticipated injury did not exist, and that when the injury accrued the plaintiff had his remedy at law. After hearing evidence as to the value of the property, the jury returned a verdict—Damages, 360*l.*

STEAM NAVIGATION.

Brazilian Steam Packet Company.—The launch of the Pernambucana, the fourth vessel for the service of this company, took place on the 6th ultimo, from Mr. Thomas Royden's yard, in Baffin-street, and the fifth and last boat for this undertaking will soon be completed.—*Liverpool Mail.*

The Gorgon Steam Frigate.—Commodore Dacres, arrived here yesterday from the Nore, with a Spanish brig in tow, which had run foul of her on her passage, but without material damage to either vessel. The arrival of this ship has excited much attention, as she is the largest Government steamer, being 1,140 tons. She mounts two 84 pounders bow and stern, on sweep slides, and six 32-pounders, long guns, on the broad side, all on the upper deck; but as on the deck below we find five ports on each side fitted with ring bolts and breeching bolts, we would ask why she has not guns mounted there? Is it that she is deeper in the water than was calculated on? because we have heard as much; and from the fact, that the lower half of the ports in question are caulked in, because they are very near the water, that the copper has been raised a streak, and her lower paddle boards are immersed four feet under the surface. Such would appear to be the case. At present her draught is 15ft. 6in forward, and 15ft. 10in. abaft; her stowage is for 500 tons of coals; but she only took in this voyage 350 tons—barely, we understand, a 10 days' consumption. She has had no coals stowed in her after boxes, and her spare heavy pieces of machinery are stowed forward, instead of the place originally intended. She has a deck below the presumed gun-deck, where 400 troops could be comfortably berthed at a time; her two engines comprise a strength of 320 horse-power, and appear of beautiful construction; her boilers are of copper. She will sail in a few days with a detachment of Marines, and supplies of provisions, for San Sebastian. We would ask any shipwright or seaman the reason why she has such an extraordinary sheer or spring in the fore part of her upper deck, and which it was remarked by visiters, must materially inconvenience the working of the foremost gun.—*Hampshire Telegraph.*

Egypt is fast becoming of moment in the opinion of other nations. Five years ago there was not a single steam-vessel of any nation plying from Egypt; now, those of England, France, Austria, and Egypt, number 18 regular opportunities to and fro every month from Alexandria. When will our government build the "Great Eastern," of 1500 tons. to go direct (both ways) between Plymouth and Alexandria in 15 days, with India mails and passengers, and thus keep the French and Austrian lines from our Indian correspondence. I shall visit Canton *via* Calcutta, and see if sufficient interest and capital cannot be realised there for the extension of Indian steam navigation to China.—*Extract of a Letter from Mr. Waghorn.*

Atlantic Steam Navigation.—A powerful steam-vessel to and from New York is to be placed on the Shannon, whereby facilities can be afforded for crossing the Atlantic, much greater than at, any English port in a given time.—*Limerick Chronicle.*

Dr. Davidge, of Saratoga, has invented a steam-boat for canal navigation, in which flexible floats or paddles, operating beneath the water, are substituted for wheels.

Iron Steamers for the Nile.—The iron steamers destined to ply on the river Nile are at present building at Greenock. The models are of the most approved description, and when ready for plying will draw from 22 to 24 inches of water. A neat handsome steamer, named the Hope, built and fitted out at Greenock, is to sail some of these days from Greenock for the Cape, where she is to run as a constant trader and packet. Almost every quarter of the globe have Clyde-built steamers plying on their rivers.—*Glasgow Chronicle.*

Another enormous Steam Ship.—Messrs. Curling and Young, of Limehouse, the builders of the British Queen, have begun a steam-ship of 2,000 tons; being 400 tons more than the British Queen; she is not to be so long as that vessel, but much wider.—*Mining Journal.*

The Great Western Steam Ship Company are about to build another vessel, of equal size to the Great Western, and she will be called the City of New York. A large cargo of African oak timber has been purchased by the company for this and other ships. The Great Western is to sail from Bristol the 27th of this month, on her fifth voyage to New York.

We understand that Government has decided on establishing a line of steam-packets between this country and Halifax, Nova Scotia, and that the contract will be thrown open for public competition. We need not point out the advantage to commercial communications which will result.

The St. George Steam Packet Company's steam-ship Sirius left London on Saturday, the 1st ultimo, and arrived at St. Petersburgh on Sunday, the 9th, left Cronstadt on Sunday, the 16th, and arrived off the London Docks Sunday afternoon, the 23rd ultimo, having performed the outward voyage in eight, and the homeward in seven days, including considerable detention both ways at the Sound.

The Royal William left Liverpool on the 21st ultimo for her second voyage to New York. She had on board 67 cabin passengers. The amount of fares for passengers, freight, cargo, parcels, and letters, considerably exceeded 3,000*l.* She carries also with her 40 tons of the new scientific and useful invention, for which Mr. C. W. Williams, the able and enterprising manager of the City of Dublin Steam Packet Company, has lately obtained a patent. From the circumstance of each ton of this discovery being able to do the work of three of the common coal, the proprietors of the vessel have been enabled this voyage to take 50 tons of cargo, with the full complement of passengers.

Prevention of Smoke from Steam Ships.—Mr Ivison's apparatus is now being applied to the furnaces of the Royal Adelaide steam-ship, preparatory to her sailing to day for London. The enterprizing proprietors of this vessel, the London, Leith, Edinburgh, and Glasgow Shipping Company, deserve great credit for having been the first to introduce this improvement to steam-ships, and the result of its application on this voyage will be looked forward to with considerable interest, not only as to its effects in entirely consuming the smoke, but in the more important one to the proprietors—the economizing of fuel. During the last ten days great numbers of engineers, manufacturers, and men of science, from different parts of the country, have visited the silk mills to witness the apparatus in full operation, and one and all of them have expressed themselves highly pleased with its efficiency.—*Edinburgh Evening Post.*

OPENING OF THE LONDON AND BIRMINGHAM RAILWAY.

The directors resident in London, attended by a few of their friends and proprietors, together with their principal officers, proceeded by a special train from the Euston station on Monday morning, the 17th ult., at a quarter past 7 o'clock. The distance from London to Birmingham (112½ miles) was accomplished in the short space of 4 hours and 39 minutes, including stoppages. The train, which (as we before observed) left at a quarter past 7 o'clock, arrived at the Harrow station at 27 minutes past seven, a distance of 11¼ miles; at Watford, a distance of 17½ miles, at 39½ minutes past 7; at Boxmoor, 24 miles, 6 minutes before 8; Berkhamstead, 28 miles, 8 o'clock precisely; Tring, 31¾ miles, 9 minutes past 8, and left that station at 25 minutes to 9; Leighton, 40 miles, 10 minutes before 9; Denbigh Hall, 47¾ miles, 5 minutes past 9; Wolverton, 52 miles, 17 minutes past 9; Rugby, 83 miles, 11 o'clock; and after passing through Coventry, arrived at Birmingham at 4 minutes past 12 o'clock.

It will be in the recollection of most of our readers, that the act of Parliament for this work was obtained in 1833, after considerable opposition, occasioned solely by this mode of travelling being then so little known and understood. The works were commenced in June, 1834, and proceeded as expeditiously as the extreme difficulty and nature of them would admit. The whole line had been projected by Mr. R. Stephenson, whose talents as an engineer are too well known to the public to require any further comment on them. The directors having had the greatest confidence in him, immediately placed this important work under his able management, and the result has fully realized their most sanguine expectations. A portion of the line, from London to Denbigh-hall, was opened in the autumn of 1837, and another portion, between Birmingham and Rugby (a distance of 21 miles), was opened in April last. The line between Rugby and Denbigh-hall presented the greatest difficulties of construction—we allude to the deep cutting called the "Blisworth cutting, which, though not the largest work of the description on the line, has, from the character of the material, been by far the most expensive and arduous. The Tring cutting contains a greater cubic content, but this material being entirely chalk, less difficulty was experienced in the execution than in the Blisworth, which consists chiefly of hard blue limestone, belonging chiefly to the volitic series of rocks, and which yielded throughout all seasons large quantities of water, which it was necessary to drain by pumping. The working of the rock in this cutting was rendered more

difficult and tedious than it otherwise would have been by the strata of rock being interstratified by these beds of blue shale, which, being impervious to water, rendered every means of drawing off (except that of pumping) unavailable. The Blisworth excavation contains 1,200,000 cubic yards, averaging 50 feet deep, for two miles in length. About 400,000 have been removed from each end to form adjoining embankments, which reach the height of 45 feet at the highest point. The remaining 400,000 have been raised up the steep side of the excavation, and deposited on the adjoining lands, forming what are termed spoil banks. The cost of this work has been 200,000*l*., and is believed to be the largest excavation of the kind ever executed.

The Kilsby-hill was, if possible, more formidable than the last mentioned work, for while the proceedings were impeded by bad material and enormous quantities of water, the means for overcoming them were confined within the narrow limits of a tunnel. Shortly after the shafts and preliminary works were organized, an extensive quicksand was discovered, which made it apparent that additional means, beyond those already contemplated, were requisite. Extra shafts were sunk, and four powerful pumping engines were erected, which continued to pump from the quicksand for six months, with scarcely a day's intermission, at the rate of 1,800 gallons per minute. By these means the difficulty of tunnelling in the sand was reduced, but still the operation was one of extreme difficulty and danger. The tunnel is 2,400 yards in length, or nearly a mile and a half, 25 feet wide, 28 feet high, and is ventilated by two large shafts, each 60 feet in diameter, one 120 feet deep, the other 90 feet. The means of tunnelling thus employed by Mr. Stephenson afforded greater facilities for ventilation going on more perfectly They appear to have answered their object most effectually, for in a few minutes after an engine and train has passed through, the vapour is carried up the shafts, and the tunnel rendered so clear that the other end may be distinctly seen. It has cost upwards of 300,000*l*.—about three times what it would have done had the casualties and difficulties been of an ordinary character. The line of railway has eight tunnels, which are nearly of similar dimensions, and passed through with impunity and without annoyance. The Wolverton viaduct is one of the most important bridges on the line. It is erected over the Ouse and Tow, near Stony Stratford. It consists of six semi-elliptical arches, each 60 feet span. The roadway is elevated 50 feet above the natural surface of the ground. It is (with the exception of the cornice and coping, which are of stone) composed entirely of brick. The aggregate amount of excavation required on the London and Birmingham Railway is about 15,000,000 of cubic yards, being equal to an average of upwards of 120,000 cubic yards per mile. To form an idea of the rapidity of the execution of this work, we may divide the whole period—say four years—by the number of miles, and we actually find that the average rate of progress has been one mile a fortnight since the first commencement of this undertaking.

The entrance of the London terminus, Euston square, is formed by a propyleum (used by the ancient Greeks as the chief entrance to their cities), consisting of four Greek Doric columns, 8 feet 6 inches in diameter, and 42 feet in height, two in front and two in the rear, with antæ at the angles of the building, surmounted by a Doric entablature and pediment; forming, altogether, a height of 72 feet. On either side of the entrance are four lodges, serving as offices for the establishment. The effect of the entrance is most striking, from its magnitude and simplicity of design. Mr. Philip Hardwick is the architect.

The terminus at Birmingham resembles that of London, only possessing greater accommodations for the directors and officers of the company, as well as refreshment rooms for persons travelling by the railway.

Many parts of the works have not yet assumed the finished character of that portion of the railway which has been hitherto in operation, and the rate of speed of the trains will be regulated accordingly. The time occupied by the directors in going down was, of course, less than will be required for the ordinary travelling, in consequence of their not having to stop at the stations; but, allowing six hours for the extreme time of the "mixed" trains, the change which will be effected in the travelling of the whole of the north of Great Britain and Ireland cannot be estimated.—*Times*.

PROGRESS OF RAILWAYS.

Eastern Counties' Railway.—We are much pleased to see this line progressing. Within these few days we have been along the line which is under contract, as far as Romford, and on the entire distance the utmost activity prevails. From Dog-row, near the Mile-end-road, where the temporary terminus is to be, the ground is cleared of the houses and buildings which have hitherto impeded the operations of the company; but we understand that this part will be commenced and finished forthwith. For a considerable distance on the London side of the Regent's Canal, the embankment to carry the railway is in course of formation. A brick and stone bridge of a substantial and handsome design, is nearly completed over the canal; between which and the river Lea the ground is fenced off; and the road bridges, four in number, in course of execution. From the river Lea to Ilford, the *whole* of the brickwork and masonry is finished, with the exception of (in a few instances) the parapets and coping. The embankment over the Stratford marshes will be shortly completed, the permanent rails being already laid on a portion of it, and for a considerable distance in the cutting by Maryland-point. The company have employed, on this part of the line, two powerful locomotive engines in place of horses for drawing the earth-waggons. In the Stratford marshes they have a contrivance to facilitate the tipping of the earth-waggons, which consists of a moveable stage of about 40 feet in length, on which are laid two lines of rails, corresponding to those on the embankment; one end of the stage rests on the embankment, the other end is supported by frame-work on wheels; on this stage the waggons are run, and the contents tipped with great rapidity. The engineer of this line has adopted a five-feet gauge; the rails are parallel, and laid throughout on transverse sleepers of elm, larch, and fir. The brickwork and masonry is generally to be praised. For a considerable distance on the London side of Ilford (where a station is to be made) the permanent rails are also laid. At Ilford the company are proceeding with great spirit, all the houses and buildings being cleared away, and the excavations proceeding rapidly. The works, as far as Romford, are being carried on with the same activity, so that by the time the earth-work between Stratford and within about a mile of Ilford is finished (which alone remains to be done), the line from Ilford to Romford will be completed, so that within a very few months from the present time, the public will be able to avail themselves of this line as far as Romford; and from the immense traffic on the great eastern road, an immediate and profitable return will be made to the shareholders. We understand that Mr. Burge has concluded with the company for a contract extending to the summit of Brentwood Hill (the heaviest work on the line), which will be commenced immediately. Two-thirds of the line to Chelmsford are now under contract.

Blackwall Railway.—Active operations are to be commenced immediately. The contractors have received instructions to proceed with the building of the viaduct, immediately the houses are cleared away, which is expected to be before the middle of the present month.

Glasgow, Paisley, Kilmarnock, and Ayr Railway.—The contracts from Ayr to Kilwinning, beyond the junction with the Ardrossan Railway, being a distance of about sixteen miles, are let in nine lots to respectable contractors for the sum of 65,637*l*. The first eleven miles to Irvine are to be completed by the 1st July, and the remaining five miles by the 1st October, 1839. The whole line is enclosed on each side by a strong wall, 4½ feet high, likewise included in the contracts, which comprise the two very beautiful bridges over the Garnock and Irvine rivers, designed by Mr. John Miller, the company's engineer, as well as several smaller bridges. The remaining portion of the thorough line—namely, from Kilwinning to Johnstone, about 14 miles, is to be immediately contracted for. The engineers are already engaged on the working plans, so that the contracts may be let, and the works commenced before the win er. The expense of this part of the line is not calculated to be very heavy, as the first sixteen miles from Ayr are executed at about 4,000*l*. per mile. If to this be added the purchase of land and the expense of rails and blocks, which altogether will not exceed the same sum, that part of the railway will be opened at an expense of not more than 8,000*l*. per mile—a circumstance almost unprecedented. The Ferguslie and Elderslie contracts, extending from Johnstone to Paisley, will be speedily commenced. The Paisley Contract, being the commencement of the joint line, consisting of an embankment on arches of masonry, comprising several street and road bridges, as well as the bridge over the river Cart, is let to Messrs. Walter and John King, and D. Lyon. The Arklestone and Ibrox contracts are also let, in one lot, to Mr. T. Brassey, on satisfactory terms. The whole of this part of the line is under the direction of Mr. Joseph Locke, ably and zealously seconded by Mr. J. E. Errington, and is to be completed in the spring of 1840. All these contracts are in active progress. The remaining portion of the joint line to King-street, in Tradeston (Glasgow), will be completed by the same period. The directors have thought it so indispensable in every respect to bring the terminus as near as possible to the Glasgow bridge, that they have decided on having this part contracted for without delay, so as to open with the rest of the line in the summer of 1840, and travellers will thus only require to cross the bridge in order to take their seats in the carriages, without the inconvenience of any intermediate passage by omnibus, so burthensome to the public. The width of the rails has been fixed at four feet eight and a half inches, with a view to insure the connexion by the projected great l nes, with the manufacturing distr.cts of the north of England. Engines are already ordered, that no delay may occur after the works are finished. A pattern carriage of each description is to be furnished by one of the best London makers, which is to serve as a model for others that may be ordered here, in order to insure uniformity of accommodation to the public. The contract for 2,000 tons of wrought-iron rails for the Ayrshire end of the railway, is taken by Messrs. Bailey, Brothers, of Liverpool; and that for 750 tons of cast-iron railway chairs, by the St. Rollox Iron Company, Glasgow.

Glasgow, Paisley, and Greenock Railway.—At the beginning of last month, the directors visited all the works along the line, and expressed themselves much gratified at their progress, notwithstanding the late inclement weather. In upwards of 20 places the ground is now covered with gangs of labourers, amounting already to about 900 men, and as rails and waggons are daily arriving, this number will soon be materially increased.

Glasgow, Paisley, and Greenock Railway.—Last month the foundations of the railway bridge that crosses Gilmour-street, Paisley, were laid, and the building has since been proceeding with spirit. The width of the railway at that point was originally intended to be 27 feet, and to contain two lines of rails; but we learn that the directors have come to the resolution of having their depôt in the spare ground adjacent to the County Buildings, and the road will now be 50 feet at the point where it crosses Gilmour-street, and will contain four lines of rails. The choice of a place for a depôt is well made, as there is no other point in the whole passage of the railway through the town where it could have been planted with such regard to general public convenience. A shaft has been sunk about the middle of the tunnel that is to run below Arklestone Hill, and rock found at the depth of about 20 yards. It is expected that rock will be found nearly the whole length of the tunnel, which is about 2.0 feet, at the depth of 60 feet, and that it would prove highly valuable for various purposes in the formation of the railway. Several houses and sheds have been erected at that point, for the use of smiths, sawyers, &c. At that part there are upwards of two hundred men at work, but they are continually on the increase. As soon as the crops are off the ground, it is expected that above 2,000 will be on the line between this and Glasgow. A strong body of men are digging on the east side of Cart, for the foundation of the bridge that spans the river. Every where a great degree of activity is manifested; and it is evident that, even during the present autumn, great progress will be made. —*Paisley Advertiser*.

Edinburgh and Newcastle Railway.—The Lord Mayor, as Chairman of the York and North Midland Railway Company, has received a most important communication from that experienced engineer, George Stephenson, Esq., who is now engaged in laying out a line of railway from Newcastle to Edinburgh, which must be of the greatest importance to the city of York, as it will preserve us in the direct line between the two great metropolitan towns of London and Edinburgh. There has been an attempt made to carry the line on the west side of the kingdom, through Lancashire, but we believe the attempt to obtain anything like a practicable line has been fruitless. Mr. Stephenson says, that he believes he shall be able to get a line from Newcastle to Edinburgh through almost as favourable a country as the York and North Midland, both with regard to levels and expense of construction; and that he has not the slightest doubt that the great thoroughfare from London to Edinburgh will pass through York, as no other line can be found equal to it.—*York Chronicle*.

Dundee and Arbroath Railway.—The facilities for rapid travelling in this district will shortly be much increased by the opening of the railway between this place and Arbroath. We understand that at a meeting of the Directors, held here on Friday last, it was resolved to open one of the rails between Arbroath and Craigie, for passengers, on the 17th ultimo. There is no hope of the work being in full operation, on both lines, before next spring. In the mean time, omnibuses will ply between Dundee and Craigie, about two miles, for the carriage of passengers and their luggage. It is expected that the locomotive engines will perform the journey in 45 minutes.—*Dundee Courier*.

Maryport and Carlisle Railway.—The workmen on this railway lately fell in with a seam of coal near Crosby. They are also working an excellent stone quarry in the same neighbourhood, which was discovered in forming an extensive cut. The engines are ordered, and are expected to be in full operation next year.

Chester and Birkenhead Railway.—We are glad to perceive that this undertaking, which excites great interest on both sides of the Mersey, is progressing rapidly. The contracts for the whole of the line have been taken on terms considerably under prime cost (?), and upwards of 700 men are now at work. Near the turnpike-road, between Brombro' and Rock Ferry, the progress of the road is already visible; and the completion of the whole line may be expected long before the period originally fixed.—*Liverpool Standard.*

Chester and Crewe Railway.—We feel pleasure in being able to announce that the cuttings have commenced on this line of railway, near the Spittal locks, Boughton. About 200 men have been set to work altogether. Matters went on very well until Tuesday last, when the excavators made their appearance *en masse* in Foregate-street, each shouldering the implements of his craft. The cause of this imposing array was the rate of payment, 3d. per cubic foot; and the workmen stated that it was impossible to earn bread and cheese at it. On that evening the whole gang were paid off; and we have been informed, that in very few instances, indeed, had they earned less than 4s. a day each man. Though the contractor did not accede to their demands, yet we are glad to observe that the cuttings are going on with great activity, on a new under-letting.—*Chester Chronicle.*

The Morecambe Bay Scheme.—We understand that Mr. Hague, who has lately surveyed Morecambe Bay, expresses himself fully satisfied that a railway can be easily carried across, and goes so far as to say that if a company will engage to give him half the land reclaimed, he will do the work at his own risk. Of the practicability of the thing we never doubted, but what we doubt is that an act of Parliament will ever be procured. There lies the difficulty, and our present impression is that it is an insurmountable one.—*Lancaster Gazette.* We see no reason why an act of Parliament may not ultimately be obtained for this line. Under present management we hold it next to impossible that the work will ever advance one step after the publication of Mr. Hague's report; but let not the inhabitants of West Cumberland despair, or suppose because Mr. Hague and his employer fail, that the difficulties our contemporary fancies he has discovered are insurmountable.—*Cumberland Pacquet.*

Preston and Wyre Railway.—A trial of the first locomotive engine which has been placed on the Preston and Wyre Railway was made on Thursday last, by Mr. Stevenson, the contractor, accompanied by a number of the most respectable inhabitants of the town and neighbourhood of Poulton. A very great concourse of persons was in attendance, and much interest was excited. Every precaution was taken to prevent accident, and the speed of the engine was at no time allowed to exceed twenty miles per hour. A number of the gentlemen present, who have been much accustomed to railway travelling, expressed themselves exceedingly gratified at the surprising smoothness and facility with which the engine glided along, which is to be attributed to the admirable manner in which the rails are laid. The distance on which the engine can now travel will speedily be increased, as there is a considerable length of the line now ready for the laying of the permanent rails.—*Preston Pilot,* Sept. 4.

Brandling Junction Railway.—The works of the Brandling Junction Railway are so far advanced, that the directors are enabled to fix the opening of the line from Redheugh to Gateshead for the 15th of October; when passengers and merchandise may be conveyed from the Newcastle and Carlisle Railway, to the company's depot on the east of Gateshead; and coals delivered into vessels at the company's drops and quay, at the east end of Hillgate. Between South Shields and Monkwearmouth, the works are also now proceeding with considerable expedition; and it is calculated that that part of the line will be ready for opening by about the 1st of January next. The deep cutting necessary to form the inclined plane on the west side of Gateshead is now finished, the permanent way laid down, the stationary engine-house nearly built, and all the arches of the viaduct over the town closed; and the wooden bridges are also prepared, and ready for putting up across Oakwellgate and West-street. A considerable portion of the quay is also built.—*Newcastle Journal.*

The Railway Delta in Lancashire.—The completion of the Manchester and Bolton Railway has enclosed a considerable tract of country within a triangular boundary of railway lines; of which the base is formed by the Liverpool and Manchester Railway line from its terminus in this town to the Kenyon junction—being a distance of rather more than ten miles. The left or westerly side of the triangle is formed by the Kenyon and Leigh junction line, of which the terminus at Bolton forms one side of the apex; this line is probably about ten miles in length. The Manchester and Bolton Railway forms the right or easterly side of the triangle, and is somewhat the shortest side; its termini are Salford and Bolton. Besides connecting the towns of Bolton and Leigh with Manchester and Salford, this delta includes the towns of Pendleton, Pendlebury, Monton, Worsley, Little Haughton, Clifton, the three Hultons, Kersley, Farnworth, Great Lever, Shakerley, Atherton, Tildesley, Astley, and Pennington. The Duke of Bridgewater's canal enters it at Patricroft, and quits the delta at Leigh. The delta includes a portion of Chat Moss, probably about four miles in length, and of breadth varying from a mile to a quarter of a mile. The principal stream in this tract is the Glazebrook, and the eastern boundary line is skirted by the Manchester, Bolton, and Bury canal. Perhaps no district in the world, of similar size, is equally favoured in the means of both land and water communication more than this little delta, which, once the scene of the triumphs of a Brindley, and the site of one of the earliest canals in England, is now girt and environed with an iron zone—enabling it, like the fabled belt of the fairy tale, to transport its treasures (mineral, manufacturing, and agricultural) in a space of time hitherto inconceivably rapid, to the most distant parts of the kingdom.—*Manchester Guardian.*

Cheltenham and Great Western Railway.—It has been currently reported here that the directors of this undertaking are pressing on the works at different parts of the line with the utmost vigour. We trust this is the case; it will not only satisfy some who may have doubted their intention so to do, but will, we think, act as a talisman with the proprietary in inducing them to pay up their calls.—*Wilts and Gloucestershire Standard.*

Sheffield, Ashton-under-Lyne, and Manchester Railway.—We have pleasure in informing our readers, that several contracts with landowners have already been completed upon the most favourable terms; and that the directors are in treaty with other parties, with every prospect of a similar result. The engineer has also received instructions to proceed immediately with the drift-way through the summet ridge, and other works connected with the tunnel, and that he has also completed the working drawings for a considerable distance of the line.—*Sheffield Mercury.*

The Manchester and Leeds Railway.—Of the great and important lines of railway communication which a few short years will see radiating from this great metropolis of manufactures, perhaps one of the most valuable and important will be that which connects the capital of the cotton with the capital of the woollen manufacture. The line runs in a direction about N.N.E. from this town to Hebden-bridge, whence its course is E.S.E. till within a few miles of Wakefield, at a point nearly due south of Leeds, and from which it makes a detour by Wakefield to the North Midland line, which carries it in a north-westerly direction to Leeds. The Manchester terminus of the line is to be in Lees-street (St. George's-road), near its junction with Oldham road. The heaviest embankment will occur in crossing the river Irk, near a place called Mills-hill, and about three quarters of a mile east of Middleton. Here a long double culvert is carried over the Irk at a height (the rails above the surface of the water) of 65 feet. The embankment does not extend much further. The railway passes over Oldham-road, Rochdale, near the Rochdale Canal Company's station, on a viaduct of sixteen arches, at a height of about fifteen or sixteen feet. The summit tunnel will, of course, be the heaviest piece of work on the whole line. This tunnel will be about a mile and a half in length, passing completely through the hill at the foot of Blackstone Edge, into the valley of Todmorden. This it does at a singularly low level, being only about 545 feet above the level of the sea, and, consequently, much lower than the level of any of the canals passing through this ridge. After leaving the summit tunnel, the line winds along the course of the valley of Todmorden. The line pursues its way till, about two miles east of Wakefield, it enters the North Midland line at a distance of fifty miles from this town; there the line proper may be said to terminate—the North Midland proceeding thence to Leeds, a distance of about ten miles further. The total distance from the Manchester to the Leeds terminus is 60 miles 50 chains, the length in a right line being about 35 miles. The nature of the country, and the necessity of passing what has been called England's vertebral chain, have caused this circuitous route to be necessary. Not only have the contracts been let for all the heavy works on the line, but in most of them very considerable progress has been made. From this town to the summit tunnel, beyond Littleborough, between 3,000 and 4,000 men are at this moment at work. We believe it is intended to have the whole line completed "in all 1840." The line will form one grand connecting link in the great chain of railway communication which is rapidly bringing Manchester into closer communication—we might almost say contact—with hitherto distant places. Not only does it connect the eastern and western shores of our island at the two great outports of Liverpool and Hull, but it forms a junction with the great eastern line of railway from London northward to Scotland, and by its points of contact with the North Midland, with its extension southwards towards Birmingham, Derby, and the Midland counties; and northward, by the York and North Midland line, to York, Newcastle, and Edinburgh; with the Leeds and Selby line, and its extension to Hull,—it leaves unreached scarcely any important district of the island, hitherto inaccessible by steam-locomotive travelling. When the lines to Leeds, to Birmingham, and the north-western line by Preston and Lancaster to Carlisle, &c., shall be completed, Manchester will then become the great centre of railway communication to all parts of Great Britain.—Abridged from the *Manchester Guardian.*

Manchester and Sheffield Railway.—At the last general meeting, Mr. Vignoles, the engineer, stated, that he considered the Dinting Vale viaduct would be accomplished for 10,000*l.* less than had been estimated. He adverted to the viaduct erected over the river Weir, which had been built of stone, but which, if constructed with timber arches, would probably have reduced the expense to 30,000*l.* The durability of timber would extend to about twenty five years: and if this plan was adopted in the construction of the viaduct at Dinting Vale, as well as in other parts of this line of railway, it would effect a saving of from 50,000*l.* to 100,000*l.* On the Carlisle Railway, to which he begged to direct their attention, there was one cutting, 100 feet deep, which had been most beautifully and efficiently executed at 7d. per cubic yard; the lowest price estimated for on the Sheffield and Manchester Railway was 8d. per yard. Glancing over the whole of the present line of railway, he would not omit to remark, on its advantages arising from the resources of the country, which abounded with the best materials calculated to facilitate the progress of the undertaking. In answer to a question put by a subscriber, Mr. Vignoles observed, that he did not think that any part of this line of railway need occupy a longer period than three years to insure its entire completion. Perhaps, continued Mr. Vignoles, it would not be amiss to state, that the viaduct over the river Weir, on the Grand Junction Railway, cost about 55*l.* per foot, including the deep foundations they had to make. This viaduct was about 300 yards long, and was twenty feet higher than the highest on this line of railway. It consisted of a number of high arches, one of a 160 feet span, another of 140 feet span, others of 100 feet, &c., and the foundations of the water arch were many feet below the river. The cost of the large viaducts with timber arches on the Newcastle and North Shields Railway, averaged from 20*l.* to 25*l.* per foot. In executing this line of Railway, he begged again to impress on their attention the advantages they possessed over most other railways, in the facility of getting materials, in the access and proximity of rocky foundations; no deep rivers to traverse, nor to tunnel through the sides of hills abounding with springs of water and loose strata.

Midland Counties Railway.—Rapid progress is making, between Sawley and Nottingham. In the neighbourhood of Beeston a large quantity of blocks are already laid.

Northampton Railway.—Arrangements are being attempted with the Birmingham Railway Company, by which a branch railway from Blisworth to this town is to be effected. In that case we are informed that the station for Northampton would be at Northampton and not at Blisworth. There would then be no station at Blisworth. It is said that the calculation of cost for such a branch railway would be 80,000*l.*—*Northampton Herald.*

North Union Railway.—A single line of road is completed all through the Ribble contract, extending as far as Farington, with the exception of a short distance at the north and south sides of the Ribble viaduct. With the assistance of a second engine which has arrived from Wigan, the second line of road will be shortly "ballasted."

South-Eastern and Dover Railway.—The extensive works of this national undertaking, at the Shakspeare Cliff and Gallery, are progressing in a manner that must be highly gratifying to their numerous well-wishers in Dover, and the shareholders generally. A few months more, and this classic height will be completely honeycombed by the tunnels; the galleries and shafts are already formed, and the drift ways connecting the shafts have been commenced. Beyond the Shakspeare, the benches on the face of the cliff are finished; and it now only remains to cut out the angular mass between them, when the line will be complete for three miles of the most difficult, though, we think, the least expensive part of this undertaking

Great Western Railway.—The receipts on the line from the London terminus to Maidenhead (only about 26 miles) have in the 88 days, from June to the end of August, amounted to nearly 21,000*l.*—*Reading Mercury.*

The North Union Railway will most probably be opened for the conveyance of passengers on the 1st of October; by which means an uninterrupted railway communication will be opened between Preston and the metropolis, and the distance of 240 miles will be traversed in the short space of 11 hours.

London and Southampton Railway.—The works of the London and Southampton Railway, in the neighbourhood of this city (Winchester), are now bringing to a close. The bridge over the Romsey road is now open to the public, and for some distance a number of labourers are employed preparatory to the permanent rails being laid. We have not heard the precise time of its being open between this city and Southampton, but we should think that by Christmas every thing would be in readiness to run between those places.—*Wiltshire Independent.*

The Bristol and Exeter Railway.—Already has the whole of the works been contracted for from Bristol to Bridgewater, at a cost averaging not more than 7,600*l.* per mile; and, indeed, the works have proceeded beyond Bridgewater. Contracts have been settled for carrying a bridge over the Parrott.

Cheltenham and Great Western Union Railway.—The contracts are let between Cheltenham and Gloucester, very satisfactorily to the directors, and the whole distance between Cirencester and Swindon will be under contract in the course of the present and next month.

South Eastern Railway.—There is now every appearance of the South Eastern Railway being speedily commenced in the Tonbridge district. A contract has been taken, and active operations will be commenced immediately on the eastern side of this town. Several purchases of land have already been made, and a jury will be empannelled on the 2nd of October, to award compensation for land not yet agreed for. As much as 1,200l. has been asked for a little more than an acre and a quarter close by.—*Maidstone Gazette.*

ENGINEERING WORKS.

Proposed Harbour at Hastings.—A numerous and highly respectable meeting was held last month at Hastings to consider the best means for the obtainment of what has long been deemed a great desideratum,—namely, the construction of a safe and commodious harbour of refuge. The mayor presided at the meeting, and Mr. Planta, Dr. M'Cabe, Mr. Richards, Mr. Elphinstone, Colonel Williams, and other gentlemen addressed the meeting on the subject, making an exposition of their several views, both as to the plans desirable to be adopted, and the advantages likely to result from the undertaking. The plan which had been proposed by Mr. Cubitt was resolved to be impracticable, but a resolution for appointing a committee "to take steps to ascertain the possibility of making a harbour, pier, or wharf at Hastings, for the accommodation of steamers, fishing-boats, coasters, and pleasure boats, at an expense not exceeding 60,000*l.*," was adopted, and a committee appointed accordingly.

Improvement of Berwick Harbour.—The projected improvements in Berwick harbour are now likely to be carried into effect with great spirit. Through the exertions of our excellent representatives in Parliament, a loan of 10,000*l.* has been obtained for the purpose from the Exchequer Loan-office. This arrangement will enable the harbour commissioners to proceed with their work without delay. They propose to deepen the river ten feet, all the way from the bridge to the bar; to clear all away to the same depth from the quays to the centre of the stream, so that vessels can lie afloat at low water; and if their means will allow of it, to deepen the bar also, so that vessels of heavy burden can enter the harbour at all times. Great improvements are also to be made on the quays. It is probable that one continuous quay will be made from the bridge to the present extremity of the low ballast quay, removing the patent slip to some other situation; and from the depth of water there will at all times be, the largest steamers, and other vessels, will be enabled to lie conveniently alongside this quay, at any part, and at all periods of the tide. The works will be commenced immediately. The dredging machine for the purpose of deepening the river is nearly ready, and the several lighters required to assist in the process are also in hand. The improvements cannot fail to contribute most materially to the prosperity of the port, and for this the town will stand much indebted both to their representatives, who have so ably assisted in procuring the means for carrying them into effect.—*Berwick Warder.*

Two skilful engineers, by order of the government, are at present making a survey and taking a plan of the river Tees, for the purpose of erecting a battery for the protection of the shipping entering that port, in case of war between this country and any foreign power.—*Leeds Intelligencer.*

NEW CHURCHES.

Ashby-de-la-Zouch New Church.—The ceremony of laying the first stone of the new church at Ashby-de-la-Zouch (which was performed by the Earl Howe), took place on Saturday, 25th August last. The church, which is now in the course of erection, under the direction of Henry J. Stevens, Esq., the architect, is to be of stone, and consists of a nave, 70 feet by 46 feet 6 inches, a recess at the east end 22 feet by 9 feet for the Communion, flanked by a vestry and porch. The principal entrance is under the tower, which is 11 feet square within, and 65 feet high, with double rectangular buttresses terminated by four lofty octangular pinnacles. The side entrances and staircases to the galleries are on the right and left of the tower, and correspond externally with the nave. The style of the church is early English, which is strictly preserved throughout; and it is capable of containing upwards of 900 persons. The contract for the erection does not exceed £2,700, and it is expected to be completed by the latter end of next year. We hear that the liberality of a few individuals has suggested the addition of a spire, for which the design is well adapted, and we sincerely hope that such a truly English termination may not be abandoned for want of sufficient funds.

Christ Church, Old Kent Road.—Thursday morning, September 13, the ceremony of the consecration of this church, lately erected in the Old Kent-road, took place. The church, which is a neat and convenient structure, is situated in the parish of St. Giles, Camberwell. We understand the ground was given by Mr. R. Turner, and the expense of the building, which was about £5,000, defrayed from a sum of money left by a gentleman for the building and endowment of the church. The church contains sitting-room for 1,200 persons, many of which are free and unappropriated.—*Times.*

A new church is being erected in the New North Road, Hoxton, under the direction of Mr. Blore, the architect; Messrs. Webb are the contractors. Amount of tender about 4,000*l.*

Donisthorpe Church.—The church which has lately been erected at Donisthorpe, was consecrated on the 25th August last, by the Lord Bishop of Lincoln. The church is built upon an acre of land, given for the purpose by Chas. Greaves, Esq., and is of the early English style of architecture. It consists of a nave 65 feet long by 35 feet 6 inches wide, a chancel at the east end 19 feet by 6 feet, and a tower, under which is the entrance, 9 feet square within, and 58 feet high, surmounted by four pinnacles. It is externally cased with stone, and the interior is fitted up with wainscot oak, and is capable of containing upwards of 400 persons, without galleries, and we believe the cost does not exceed £1,500. Half the accommodation is free and unappropriated.—*Derby Mercury.*

FOREIGN INTELLIGENCE.

Versailles.—The palace and gardens of Versailles have, since the time of Louis XIII., cost 1,200 millions of francs, or nearly 50 millions sterling; and considering that the value of money a hundred years ago was twice or thrice greater than now, the actual expense in the value of our time is much more.

Berlin.—On the 18th of May the first stone was laid at Berlin of an hospital for old and decayed householders, called, in honour of his Russian Majesty, the Nicholas Burgher Hospital.

Russia.—Among the colossal works now erecting at Odessa, the great emporium on the Black Sea, is a gigantic staircase of white marble of 200 steps, in ten divisions with landing places, which, as they gradually diminish from 350 feet wide at the bottom to 175 feet at the top, present the appearance of a complete pyramid. It is decorated with thirty Corinthian columns, and is on the face of a hill, 100 feet above the level of the sea, uniting the upper town to the harbour and lower town.

First Bridge over the Nile.—The works on this undertaking have at last commenced, and 24,000 men are now employed upon the bed of the river, the construction of dams, &c., besides 340 carts and 500 carpenters from Alexandria. In order to avoid any deficiency of labourers, four regiments of infantry are employed, who have a camp in the neighbourhood. This gigantic bridge is on the south corner of the Delta, 25 miles from Cairo, just at the point where the Nile divides into two branches. It is intended also to cut a sluice to keep up the waters in winter and spring, and canals are to be cut from the river to irrigate the land. A railway eleven miles in length has been commenced, to communicate between the stone quarries of Mokatum and the bridge.

Dock at Cherbourg.—Two thousand four hundred men are now employed in excavating the new dock at Cherbourg, which is on the same scale of grandeur as the other works at that port.

We understand that an English gentleman of science has been associated by his excellency the lieut.-governor with the civil engineer, who had been recommended to his excellency to carry into effect the resolution and vote of the House of Assembly for an exploration, with a view to the removal of the obstructions to the navigation of the river St. John, from Fredericton upwards. This is a very desirable object, and we have little doubt that steam-boats will be enabled to ply as high as the neighbourhood of the Grand Falls, the waters of the river above which might easily be connected in a navigable manner with those below by means of a canal. We have been as high as th eTobique, and the St John to that point keeps its width in a most remarkable manner; while the obstructions to navigation above Woodstock are slight, and it is probable could be easily removed. The undertaking, therefore, is one of great importance, and will doubtless lead to beneficial results.—*Fredericton Sentinel.*

Holland.—The Estates of Holland have declared themselves favourable to the project for draining the lake of Haarlem, and considering the importance of such an undertaking, have granted the sum of 60,000 per annum for ten years, each of the two parts of the province (North and South Holland) to contribute equally.

The church of the Bernhardines, at Posen, in Prussian Poland, was destroyed by fire on the 30th August. The following account of this event is given by a German paper:—"The alarm was given at 7 o'clock. Since the dissolution of the monasteries the church had not been used for divine service, but served latterly as a hay magazine. The cause of the fire is not yet known. Malice is hardly to be imagined, and yet the spontaneous combustion of the hay cannot be assumed, as it was last year's crop. However, the fire was not discovered till the whole church was in flames. An hour had scarcely elapsed when the flames reached the steeple, which soon appeared like a pyramid of fire rising in the dark sky, and thus affording a splendid sight. The whole population hastened to the spot, partly to afford assistance, if possible, partly to observe from the great Bernhardine-square the awfully sublime scene. At length the steeple fell with a tremendous crash, but did no mischief. The church itself burned all the night long, and this morning only some bare walls remain. Happily for the town, the wind, which was rather high, blew in such a direction as to hinder the spreading of the fire. Had it blown in another direction, either one of the finest streets or the convent itself, with the great church and its two magnificent towers, would have fallen a prey to the fury of the flames. Happily no lives were lost."—*Hamburgh paper.*

Belgium.—The opening of the section of the railway from Bruges to Ostend, took place on Tuesday, 28th August, with great ceremony, in presence of their Majesties, and a great number of persons of distinction. On account of the want of locomotives, one journey a day only is made. Between Bruges and Ghent no short trips are allowed, and no passengers for pleasure, only for business. Preparations are already being made to profit by the anticipated increase of traffic; two steam boats, instead of one, are now placed on the station between London and Ostend, by the General Steam Navigation Company, and through the enterprize of some of the English established at Bruges, another steam boat will, by the beginning of October, be placed there, and another is about to be built at Bruges. The English government has long talked about establishing daily mail communication, but it is not yet done.

Belgium.—The Antwerp papers mention that the Belgian Government had just published a royal decree, by which it is determined that the Hainault railway shall pass by the way of Soignies, and that from Namur to Brussels through the valleys of the Orneau. The projected route by Tirlemont has accordingly been abandoned.

Belgian Railways.—There are now six lines open in Belgium; from Mechlin to Brussels, Antwerp, Louvain and Dendermond; from Dendermond to Ghent; Ghent to Bruges, Bruges to Ostend; Louvain to Tirlemont; Tirlemont to Waremmes, and Waremmes to Ans. The total length is 256,000 metres, or 160 miles. The communication from London to Brussels is now in 20 hours.

Alexandria.—The two-mile railway mentioned in my letter of last month, that was to be laid outside the Roetta gates of Alexandria, for the purpose of exhibiting one of the locomotive engines sent out for the railroad across the Suez desert, has been completed, and the engine tried on it. It went full forty miles an hour, and the Pacha and people were highly satisfied and delighted therewith. This portion of railroad has been taken up again, as it was merely laid for the experimental purpose of trying the locomotive engine, and gave, as well as the engine, perfect satisfaction. —*Shipping Gazette.*

Switzerland.—The beautiful village of Heiden, near Appenzell, running a length of nearly half a league, and containing upwards of 100 houses, together with the church, was totally destroyed on the 7th ultimo by fire, originating in an iron foundry established there.

Rome.—The Pope has given orders for the preservation of the mausoleum lately discovered before the Porta Maggiore.

The colossal bronze statue of Marshal Mortier, erected at Cateau, near Cambrai Nord, was inaugurated with great ceremony on the 16th ult. The Prefect of the Department delivered an impressive oration, which was received with repeated cheers of approbation and shouts of *Vive le Roi!* On the face of the pedestal is inscribed—"Au Maréchal Mortier, né au Cateau en 1768, mort assassiné à côté du Roi, le 28 Juillet, 1835." On the opposite side "Mutten-Thal, Hanovre, Dierustein, Ocana, Moscou, Lutzen, furent les principeaux théâtres de sa gloire."

Potsdam Railway.—The first half from Potsdam to Berlin is to be opened in September by the Emperor of Russia. The directors hope to have the remaining section open in the autumn, when the passage can be effected in half an hour; but this part has a pretty long cutting 35 feet deep, with a bridge and afterwards a tunnel, carrying the high road over the railway.

St. Germain Railway.—The number of passengers in the first year, from 26th August, 1837, to 26th August, 1838, has been 1,375,396, and the receipts 1,550,144f. 35c., or 60,000*l.*

The St. Cloud Railway was opened to the public on the 7th ult. A second trial was made of the locomotive engine, the Stephenson, which started with a train of ten waggons soon after 10 o'clock, and arrived in 22 minutes; but on its return only took 19 minutes. The St. Cloud coaches, by the ordinary road, took an hour.

Constantinople.—New buildings are proceeding with great activity; among others are a naval school, lazaretto, steam saw-mill, &c. A theatre for Europeans is in contemplation, the funds to be raised by a company with 500 shares of 1,000 piastres each.

The Versailles and St. Cloud Railway.—The works beyond the latter place are going on with great rapidity. The grand tunnel is nearly cleared, and will require but little being done to it during the winter. The viaduct at Ville d'Avrey having slightly given way in two places, it has to be supported by two buttresses, which will cost as much as the arch itself. The directors have yielded to the remonstrances of the town of Versailles and the authorities of the department, and have determined to form a tunnel under the Avenue de Picardie, instead of the open cut at first intended; this work is begun, as well as that in the park of Clagny. It is expected that this remaining portion of the road will be opened in April, unless the works are impeded by unfavourable weather.

The Leipsic Railway.—Leipsic, Sept. 10.—On the 16th instant the road opens from Leipsic to Dahlen, and from Dresden to Oberau, so that there will be 42 miles in operation. The King went yesterday along the line, and came the whole distance from Dresden to Leipsic (75 miles) in five hours and a half. Up to the 31st of August, 360,508 persons have travelled along the railway in 2,964 journeys, or 122 per voyage.

Amsterdam, Sept. 19.—We learn that his Majesty will lay before the States-General, in the next session, a proposal of law relative to the iron railway to the Rhine, in order to prevent the delays that have taken place with respect to the Haarlem railway. This law seems to have only a special object, and not to interfere with the rights accruing to the government from the imperial line of 1810.

LIST OF PATENTS GRANTED BETWEEN THE 31st OF AUGUST AND THE 27th OF SEPTEMBER, 1838, BOTH INCLUSIVE.

John Keys, of Sutton, in the Parish of Prescot, in the County of Lancaster, Copper Smelter, and William Thompson Clough, of Eccleston, in the parish of Prescot, for "A Method or Process for the Manufacture of Sulphuric Acid from Copper Ore, Copper Regulus, and Sulphuret of Zinc."—31st August; 6 months.

Morton Balmanno, of Queen Street, Cheapside, in the City of London, Merchant, for "A New and improved Method of Making and Manufacturing Paper, Pasteboard, Felt, and Tissues."—6th September; 6 months.

Timothy Burstall, of Leith, in that part of the United Kingdom called Scotland, Engineer, for "Certain Improvements in Steam-Engines, and in Apparatus to be used therewith, or with any other Construction of the Steam-Engine, or other Motive Power, for the more smooth and easy Conveyance of Goods and Passengers on Land and Water, part of which will be applicable to Water Power."—6th September; 6 months.

Henry Gibbs, of Birmingham, in the county of Warwick, Button-manufacturer, for "An Improved Perforated Button."—6th September; 6 months.

John Frederick Bourne, of Manchester, in the County of Lancaster, Engineer, and John Bartley, Jun., of the same place, Engineer, for "Certain Improvements in the Construction of Wheels to be used upon Railways and other Roads, and which Improvements are also applicable to the Construction of Wheels in general."—6th September; 6 months.

Miles Berry, of 66, Chancery Lane, in the County of Middlesex, Patent Agent, for "Certain Improvements applicable to Certain Parts of the Process generally used for the Manufacturing and Refining of Sugar; communicated by a Foreigner residing Abroad."—6th September; 6 months.

Joseph Brown, of the Minories, in the Liberty of the Tower of London, Upholsterer, for "Improvements in Beds, Sofas, Chairs, and other Articles of Furniture, to render them more suitable for travelling and other Purposes."—8th September; 6 months.

James Ulric Vaucher, of Geneva, in Switzerland, but now residing at Manchester, Gentleman, for "Certain Improvements in Fire Engines, Watering Engines, and other Hydraulic Machines, and Apparatus for Raising or Propelling Water and other Fluids, some of which Improvements are also applicable to Steam Engines."—8th September; 6 months.

Henry Dunnington, of Nottingham, Lace Manufacturer, for "Improvements in Machinery employed in making Frame Work, Knitting, or Stocking Fabrics."—10th September; 6 months.

Alexander Southwood Stocker, and Clement Heely, Manufacturers, of Birmingham, in the County of Warwick, for "Improvements in Straps for Wearing Apparel."—10th September; 6 months.

Ambroise Ador, of Leicester-square, in the County of Middlesex, for "Certain Improvements on Lamps, or Apparatus for Producing or Affording Light."—13th September; 6 months.

Thomas Swinburne, Esq., of South Square, Gray's Inn, for "Certain Improvements in Water-Closets, and other Conveniences of the kind."—13th September; 6 months.

Archibald M'Lellan, of the City of Glasgow, Coach Builder, for "Certain Improvements upon the Springs and Braces of Wheel-Carriages, and upon the mode of hanging such Carriages."—13th September; 6 months.

Frederick Le Mesurier, of New Street, Saint Peters Port, in the Island of Guernsey, Gentleman, for "A certain Improvement or certain Improvements in the Construction of Pumps, for raising Water or other Fluids."—13th September; 6 months.

Sir Hugh Pigot, of Foley Place, Marylebone, and County of Middlesex, Knight, "For a certain Engine or Engines, useful as Steam-Engines, Pumps, or Propellers of Vessels or Machinery."—13th September; 6 months

William Day, of Gate Street, in the Parish of Saint Giles-in-the-Fields, in the County of Middlesex, Lithographer, for "An improved Mode or Method of applying and combining Timber and other Materials used in the Construction of Ships or Vessels, Masts, Yards, Beams, Piers, Bridges, and various other Purposes."—20th September; 6 months.

James Nasmyth, of Patricroft, near Manchester, in the County of Lancaster, Engineer, for "Certain Improvements in Machinery, Tools, or Apparatus, for Cutting or Plaining Metals and other Substances, and in securing or fastening the Keys or Cottars used in such Machinery and other Machinery where Keys or Cottars are commonly applied."—20th September; 6 months.

Joseph Hall, of Over, in the County of Chester, Plumber, for "Improvements in the Manufacture of Salt."—13th September; 6 months.

John Chanter, of Earl Street, Blackfriars, in the County of Surrey, Esquire, and John Grantham, of Liverpool, Engineer, for "Improvements in Furnaces for Steam Boilers."—13th September; 6 months.

Edwin Bottomly, of South Crossland, in the Parish of Almondbury, in the County of York, Clothier, for "Certain Improvement or Improvements applicable to Power and Hand Looms."—13th September; 6 months.

Edward Massey, of King Street, Clerkenwell, in the County of Middlesex, Watchmaker, for "Improvements in Watches and Machines for keeping Time."—13th September; 6 months.

James Wapshare, of Bath, in the County of Somerset, Gentleman, for "Certain Improvements in the Application of Heat, for the Purpose of drying Wool, Woollen Yarns, Woollen Cloths, and other Articles, and other Improvements connected with the Use of the Press, in the Process of Dressing or Finishing Woollen Cloths."—13th September; 6 months.

Joseph Wilkinson, of the Quadrant, Regent Street, in the Parish of St. James, in the City of Westminster, Ironmonger and Engineer, for "Certain Improvements in the Construction of Tram or Railways, and in the Carriages to be used thereon."—18th September; 6 months.

Robert William Sievier, of Henrietta Street, Cavendish Square, in the county of Middlesex, Gentleman, for "Certain Improvements in Rigger Pulley Bands, for driving Machinery, and Ropes and Lines for other Purposes."—20th September; 6 months.

John Thomas Betts, of Smithfield Bars, in the City of London, Rectifier, for "Improvements in the Manufacture of Gin, which he intends to denominate Betts' Patent Gin, or Betts' Patent Stomachic Gin. Communicated by a Foreigner residing Abroad."—21st September; 6 months.

James Walton, of Sowerby Bridge, in the Parish of Halifax, in the County of York, Clothdresser and Frizer, for "Certain Improvements in Machinery for Making Wire Cards for Carding Cotton, Wool, Silk, Tow, and other Fibrous Substances of the like Nature."—21st September; 6 months.

John White, of Haddington, North Britain, Ironmonger, for "Certain Improvements in the Construction of Ovens and heated Air Stoves."—27th September; 6 months.

Edmond Henze, of Fenton's Hotel, St. James's Street, Merchant, for "Improvements in the Manufacture of Dextrine."—27th September; 6 months.

John Joseph Charles Sheridan, of Ironmonger Lane, Chemist, for "An Improvement in the Manufacture of Soap."—27th September; 6 months.

John Hughes Rees, Esq., of Penymaes, in the county of Carmarthen, for "Certain Improvements in the Machinery applicable to the raising of Water for propelling Boats, Carriages, and other Machinery."—27th September; 6 months.

Emile Alexis Fanquet Delarue, Jun., of Bacon's Hotel, St. Paul's Churchyard, for "Certain Improvements in Printing, and fixing Red and other Colours in which Red forms a constituent Part upon Cotton, Silk, Woollen, and other Fabrics."—27th September: 6 months.

MISCELLANEA.

Asphalte Experiments.—By the proceedings of the Prussian Association for Promoting the Arts, we see that they have laid down a pavement of nine different compositions, of asphalte, coal tar, oil, sand, lime, chalk, &c. Observations will be made to ascertain the durability and relative properties of the several compositions.

The remains of a Roman villa have recently been found on the estate of Mr. John Henry Shore, at Whatley, near Frome, Somersetshire. Earth to the depth of three feet has been removed, and a fine tessellated pavement uncovered, consisting, as it at present appears, of two rooms connected together; one of them being about 32 feet by 20, and the other 22 feet by 14. The pavement is tolerably perfect, but has suffered damage in one part. The tesseræ is very small and of seven different colours. Some coins, and which are believed to be of the reign of Constantine, Roman pottery, and other curious antiquities, were dug up at the time the excavation was made. It is believed, from the appearance of the surrounding earth, that if the excavations were continued further interesting discoveries would be made.

Fire at the London and Birmingham Railway Station.—On Sunday evening, 22nd ult., an alarm was given at the station at Euston-square, and along the line of road for a considerable distance, that the large warehouses erected at Camden-town for depositing heavy luggage, &c., were on fire. Men were dispatched in all directions to the spot, and found the whole of the straw, with which the flooring of the place was covered, in one mass of blaze, which had reached a tarpauling, covering 20 or 30 tons of luggage, which was also on fire. The luggage consisted partly of articles of a combustible nature, among which, in consequence of the shooting season, there was a great quantity of gunpowder, for which the greatest fears were entertained, but owing to the intrepidity of one of the engineers, it was speedily arrested; he having mounted the pile of luggage, and, at the risk of his life, succeeded in removing the burning tarpauling. A plentiful supply of water was immediately procured, and by the exertions of the men, we are happy to say the injury sustained was very slight; but had it not been discovered in the manner it was, doubtless property to a very considerable amount would have become a sacrifice. The fire originated through the carelessness of one of the porters in leaving a lantern among the straw, whilst he went about something, with the wick so high that it melted the solder of the lantern, and causing it to fall to pieces, exposed the bare light among the straw. The directors have ordered the man's discharge forthwith.

Railway Switch Signal.—We have recently had an opportunity of inspecting a railway signal erected at the Grand Junction station, Birmingham, which, from its great simplicity, and the unerring certainty with which it conveys the requisite information, as to the state of the points, to the drivers of locomotive engines, both by night and day, appears to be an invention highly important, not only to the proprietors of railroads but to the public generally, as it will greatly tend to prevent those accidents which have occasionally occurred in consequence of the points (or switches as they are called) being left in a wrong position. The invention consists of two discs, about two feet in diameter, placed at right angles, surmounted by a lantern showing four lights, but of three distinct colours—viz., two red, one blue, and one white; the discs are painted to correspond. This apparatus is firmly attached to the top of the eccentric shaft employed in moving the points, and consequently turns with it with unerring certainty, and can be seen at a great distance, affording the enginemen or drivers ample time to govern the trains according to circumstances. The signal is the invention of Dr. Church, of Birmingham, and has been patented; and there is no doubt it will soon be adopted by the railway companies generally.—*Midland Counties Herald.*

Captain Norton's Percussion Lead, for exploding Charges of Powder at the Bottom of Harbours and Rivers.—A sea lead is charged at its heavy end with a small iron tube, having a percussion cap at each end, filled with gunpowder; the lead has two eyes or rings on its sides in a straight line, through which a cord is run, one end being attached to the box of powder, at the bottom of the water; the lead is allowed to slide along the cord, and on striking the box, explodes it; a thin piece of sheet lead or copper being fixed to the box, when the percussion primer strikes. Captain Norton successfully tried his percussion lead at the Polytechnic Institution, Regent Street, on the 19th ultimo; he proposes this means as a substitute for the fuzes at present in use, being more simple, less costly, and easy of application.

Meteorology.—The Annals of the Board of Longitude, for 1834, contains an article by M. Arago, on the "Mean temperature of the Globe, and on the heat of summer in the 19th century, in different regions, as compared with periods more remote." This learned astronomer proves, that the general temperature of the earth has not varied the tenth-part of a degree in 2000 years; and that the climate has become neither warmer nor colder in any place in which the physical aspect has not sensibly changed during a long period of ages; thus the palm-tree and vine flourish still at the gates of Jericho and upon the banks of the Jordan, and that no difference in the time of the fruit arriving at maturity has been observed for 33 ages; but during this period, the hand of man has neither cut down the forests nor drained the soil of Palestine. Do the same things exist as regards France?—The most incontestible proofs attest the contrary. A few ages past, good wine was made both in England and in the north of France; now, on account of the coldness of the summers, such a thing would be impossible. The old chronicles inform us, that in England the vine was formerly cultivated in the open air, and that wine was made there. The Emperor Julian, during his stay at Paris, drank the wine of Surêne; the City of Valenciennes was surrounded with vineyards. In 1456, the land between the gardens of the palace of Comté and the walls of this city was called the "Vineyard of La Salles." But a most conclusive fact is furnished by Outranan, in his history of Valenciennes, who, expressing himself in his quaint style, says, "This year (1575) was so abundant in vine, that there are sold in Valenciennes every Saturday, at least 1800 pieces." We read, likewise, in the "Recollections of Douai," by M. Plouvian, that in the 13th and 14th centuries, there was made in that city about 20,000 pots of wine per annum, each equal to two litres, eight catititus; the largest garden for vines being situated upon the ground now occupied by the Arsenal, and in the vicinity of the "Trinitanics." Meteorologists attribute this sensible diminution of summer heat to the thinning of the forests, and to the almost complete disappearance of the peat bogs and stagnant waters, and to the rivers being confined to their proper channels by embankments, which formerly overflowed the country. North America, at the same time, presents us with a like phenomena. During the few years since the various works for draining the country have been carried into effect, it has been remarked that the summers have become colder in that part of the New World. *(Echo de la Frontera.)* It occursto us, from our own observations, that the French editor is wrong in his statements, both in the United States and in Mexico. In proportion as the land is altered, the temperature is known to increase. Robertson, in his "History of America," accounts for the greater degree of cold in the same parallels of latitude in the New World to those in the Old World, by the dense forests intercepting the sun's rays, and thus the earth is kept cool, and also to the exhalations from the marshes, as it is a well known chemical fact, that evaporation produces cold; so that we apprehend that M. Arago is right, when he says, that where no sensible alteration has taken place in the physical features of a country, no alteration will be, as has been observed, in the temperature.—*Editor C. E. and A. Journal.*

Iron Welding.—A practice has for some time prevailed at Keswick, of welding iron and steel with a mineral which is said to be very abundant in that neighbourhood, and is found to answer the purpose much better than sand or borax, inasmuch as it affords a decidedly better protection to the fusing metals. It is used in the same common or simple way as sand, requiring no further care or management. Two, three, or more pieces of cast steel may be welded together, and drawn out, hardened, and broken across the junctures, which cannot be observed; or iron and cast steel can be welded together in the same way, as perfectly and with as much ease as the hardest steel or iron.—*Carlisle Patriot.*

Railway Charges.—Considerable dissatisfaction has been expressed, and very justly, we think, during the past week, by the manufacturers and tradesmen generally in the town, at the sudden increase in the charge of carriage by the directors of the Birmingham and London Railway Company, from 1d. to 1½d. per lb. It is, we think, somewhat early for this company, who has in a measure possessed itself of the only means of transit between the metropolis and the heart of the kingdom, to put the screw on the confiding public. What we would recommend would be, that a public meeting of the inhabitants be immediately called, with the view to coming at once to an understanding with the directors upon the point whether or not the whole country is to be subject to the caprice or cupidity of the railway monopolists.—*Birmingham Advertiser.*

The Thames Water.—Sir Anthony Carlisle, in the branch of his work just published on health and old age, devoted to the medical topography of Lodnon, says, that "the ebb and flow of the tides in the river, and the regurgitation of fresh water, deposit on the exposed banks a large portion of the filth produced in the metropolis, and subject to evaporation along the wide spaces of the borders of the river. As the sea water does not ascend through the town, a large portion of the Thames water charged with filth must pass and repass the town at every tide, and deposit its sediment. The shores of the river, as it ebbs through the town, are largely exposed at low water, and exhibit banks of putrescent mud, which, in the summer season, abounds with the larva of gnats, which live upon, and help to consume the filth; in fact they are invaluable scavengers."

Ancient Edifice.—M. Prosper Merimée, who has recently been on an inspecting tour, states, that the church of Conques is a perfect model of Byzantine architecture, and displays the whole state of architectural knowledge at the beginning of the eleventh century. It is one of the most beautiful edifices of its kind in France, and the town itself possesses a number of relics which are valuable either for their materials, their workmanship, or their antiquity,—for some belong to the time of Charlemagne. Almost all are enriched with engraved stones, and one is ornamented with paintings in enamel. The date of this is 1106, and settles a long-disputed point on the exact period of the Middle Ages when this method of painting was employed.

Mineral Produce of Great Britain.—We give the following estimate of the mineral produce of Great Britain, on an average of years and prices, from the *Mining Review*:—

	Quantity.	Value.
Silver	10,000 lbs. Troy	£80,000
Copper	13,000 tons	1,300,000
Tin	5,500 tons	550,000
Lead	46,000 tons	950,000
Iron	900,000 tons	7,000,000
Coal	25,000,000 tons	10,000,000
Salt, Alum, and other minor produce, more than		1,000,000
Total value probably exceeds		£20,000,00

Geological Discovery.—An interesting geological specimen has just been discovered, at the depth of thirty-seven feet below the surface of the rock, in the new red sandstone at Storton-hill quarries, four miles from Birkenhead, in Cheshire. It is a series of impressions of footsteps, in relief, of an extinct animal, called by Professor Kaup the Cheosotherium, the existence of which in former ages, has been known only from similar marks having been found. The impressions bear a strong resemblance to the human hand. Mr. Tomkinson, the lessee of the quarry, on being made acquainted with the value of the slabs on which these marks appear, has, in the most liberal manner, not only given one up, without charge, to the Natura History Society of this town, but will convey it to its destination at his own expense. He purposes, also, to send another to the London Geological Society. Professor Buckland has given an account, illustrated by engravings, in his "Bridgewater Treatise," of the impressions of footsteps of the same extinct animal discovered in the quarries of Hessberg, in Saxony. The slab of sandstone is in the British Museum.—*Liverpool Albion.*

Projectile Experiments.—A large concourse of people assembled at the Pier-head on Thursday June 21st, to witness a variety of experiments made on a new projection to afford assistance to distressed vessels at sea. The improvement, we understand, cosists in the use of rockets to propel a rope to any object at sea, instead of a mortar, as hitherto used with Captain Manby's apparatus. The advantage, as shown by the experiment on Thursday, is evident; as in the first place the ascension of the rocket is more even than that of a shell projected from a mortar; and in the second, a great increase of power is gained. The result of the experiments was perfectly satisfactory, a rope being several times thrown to a boat moored about 260 feet at sea, as well as 200 feet beyond, without the failure hitherto so frequently experienced with the mortar, which detached itself from the rope by the violence of its exit. The manner also of directing the rocket, which is done by a case mounted on a swivel, is simple and effectual. Afterwards the qualities of a new life-boat were tested, by upsetting it near the pier, with the anticipation that it would right itself. This, however, did not prove the case in every instance, probably from the utter placidity of the sea, which was undisturbed even by a ruffle.—*Brighton paper.*

Raising of her Majesty's Ship Pincher.—The wreck of the ill-fated schooner Pincher, which sank off Bognor some time since, was raised on June 19th by two government lighters, after some delay, caused by waiting for tide, fine weather, &c. The tackling broke in the first instance, but the second attempt was attended with success. A government steamer, which was in readiness, took the Pincher and the two lighters in tow, and brought them into Portsmouth harbour the same evening. —*Sussex Express.*

NOTICES TO CORRESPONDENTS.

We shall feel obliged to the Profession for accounts of Works in Progress, New Inventions, and Discoveries; it would be doing us a great service if our Country Subscribers will forward us any Newspaper containing information connected with the objects of our Journal.

Subscribers are particularly requested to make up their sets of the Journal, as the First Volume will be completed with the December number, which will contain an index, title page, and introduction. In consequence of this additional matter, the December number will be charged sixpence *extra*.

Books for Review should be sent early in the Month—Communications on or before the 20th—and Advertisements on or before the 25th instant.

PROSPECTUS.

1. The Plan now submitted to the Public is for the establishment, within the confines of London, of an Institution, with extensive Botanic Gardens, Library, Museum, Studio, Hot-houses, Conservatories, &c.

2. The Ground selected for the Gardens is admirably adapted for the purpose, both as regards its form and situation, being the space included in the inner circle of the Regent's Park. It contains eighteen acres, which will be appropriated for the reception of the plants indigenous to the several divisions of the globe. The Ground will be disposed in imitation of the Gardens of different countries, and the architectural ornaments will also be in unison with the peculiar features of the respective regions.

3. Conservatories, which are so essential in this country, will be erected upon a scale commensurate with this Undertaking. Extensive Lawns, Terraces, and Promenades, interspersed with Parterres, Fountains, Statues, Vases, and other works of art, will be introduced.

4. There will also be a Lake of sufficient magnitude for the growth of aquatic plants, and likewise Artificial Rocks for the disposition of mountainous productions.

5. The plants will be arranged according to the two great systems of classification—the Artificial and the Natural.

6. An important appendage contemplated, is the formation of a Medico-botanical Garden.

7. A new and valuable feature of the present project, will be a collection of all the plants applicable to the arts and manufactures, of whatever country they may be natives, with a view to extend the cultivation of those which may prove most useful. By this means many products which are now obtained with great labour and expense, may be supplied in our own climate.

8. A well-selected Botanic Library and Museum will be attached to the Institution;* and also a Studio, which will be set apart for those who may be desirous of copying the productions of Nature; and able Professors of Botany and Drawing will be appointed to give Instructions and Lectures during a considerable portion of the year.

9. Public Botanical Exhibitions, which may lead to the improvement of the Science, will be encouraged, and every facility will be given to professional Florists and Nurserymen, to obtain specimens of rare and valuable plants, and to display those of their own growth.

10. Thus, for the study of their respective pursuits, ample opportunities will be afforded to the Botanist, the Medical Student, the Artist, the Gardener, the Manufacturer, and to all those who wish to apply the study of botanical productions to the improvement and embellishment of their respective departments in the Arts and Sciences.

11. The Constitution of this Society is founded upon laws similar to those which regulate other scientific bodies; its Government consisting of a President and Council, with a Society of Fellows and Members, which is intended to be incorporated by Royal Charter.

Possession has been obtained of the Ground, and active operations commenced.

Donations paid into the Bankers' hands before the 1st of January, 1839, will entitle the Donors to the following privileges, and exempt them from Annual Subscriptions:—

A payment of 10 guineas will entitle the Donor to a Free Admission for Life.
20 guineas will entitle the Donor to become a Fellow of this Society for Life, and to the introduction of Two Friends to the Gardens.
30 guineas, ditto, ditto, and to the possession of One Ivory Transferable Ticket, admitting Two Persons.
50 guineas, ditto, ditto, and Two Ivory Transferable Tickets, each admitting Two Persons.
100 guineas, ditto, ditto, and Three Ivory Transferable Tickets, each admitting Two Persons.

The qualification to become a Fellow by *Annual Subscription*, will be the payment of an Entrance Fee of Five Guineas, and an Annual Subscription of Two Guineas, commencing on the first day of January next.

Books for Donations and Subscriptions are opened at the following Bankers:—

MESSRS. COUTTS AND CO.
MESSRS. BARCLAY AND CO.
MESSRS. BOSANQUET AND CO.
MESSRS. DRUMMOND AND CO.
MESSRS. MASTERMAN PETERS, AND CO.
MESSRS. TWININGS.
MESSRS. DIXON, BROOKS, AND DIXON.
SIR JOHN LUBBOCK, BART.. FORSTER AND CO.
SIR CLAUDE SCOTT, BART. AND CO.

And at the Offices of the Society, No. 11, Parliament Street, and at the Gardens.

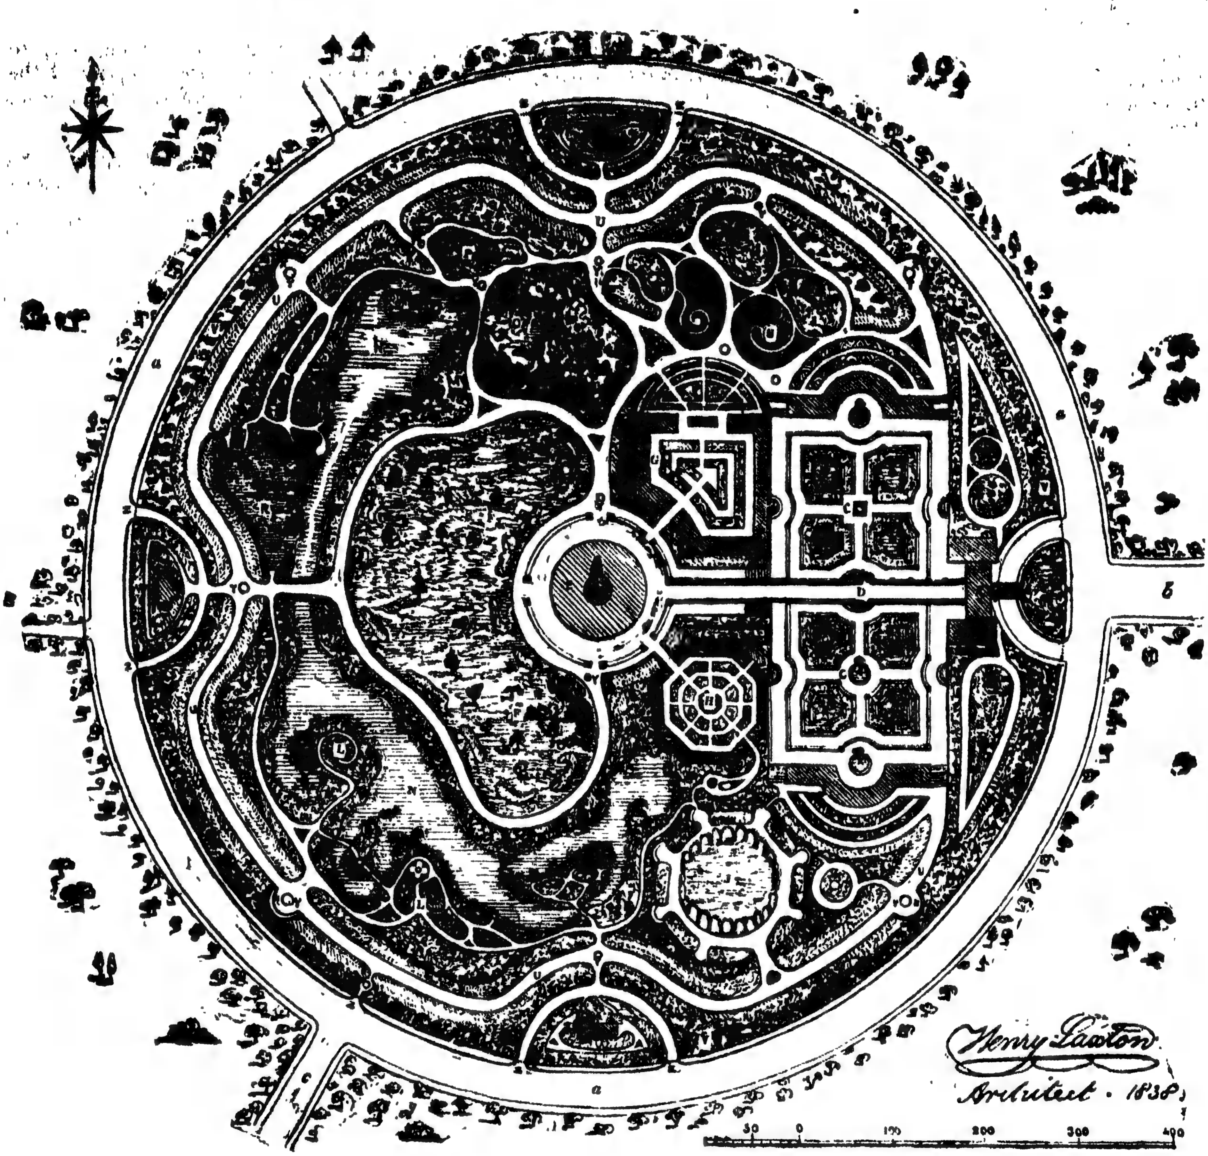
JAMES DE CARLE SOWERBY, F.L.S.
PHILIP EDWARD BARNES,
} Secretaries.

Temporary Offices, No. 11, Parliament Street.

* The Provisional Committee avail themselves of this opportunity to return thanks for several valuable Contributions already received.

THE GARDENS OF THE ROYAL BOTANIC SOCIETY,

INNER CIRCLE REGENT'S PARK.



DESCRIPTION OF THE PLAN.

A.—Principal Building, approached by a semi-circular drive, containing the Botanical Museum and Library, Reading, Drawing, and Lecture-rooms, and offices for the general business of the Institution.

B. B.—Gardens attached to the Establishment.

C. C.—Italian Garden with raised terraces, fountains, and *parterres*, ornamented by ballustrading vases, figures, and other works of art; with Conservatory at one end, and Casino at the other.

D.—Grand Promenade formed upon a viaduct, and protected on each side by ballustrading, enriched by vases and figures.

E.—Extensive domed Conservatory for large specimens of the exotics and creeping plants.

F.—English Garden—a lawn embellished with *parterres*, ornamental trees, and shrubs.

G.—Medico-Botanic Garden, with extensive range of Conservatories, Stoves, and Hot-houses.

H.—Dutch Garden formed geometrically, with canal around, and fountain in the centre.

J.—Rosarium—a level lawn, with arched trellis work, and borders for every kind of rose.

K.—Swiss cottage and garden upon an island.

L.—Oriental garden, with Persian and Chinese kiosks, pagodas, bridges, &c.

M.—American garden.

N.—Lake for aquatic plants, and small islands for the willow, and other plants requiring moist localities.

O.—Artificial rock work, for the growth of rock plants, with reservoir at the top and cascade.

P.—Hermitage.

Q.—Arboretum and shrubbery.

R.—Lawn, with drooping ash trees.

S.—Mound, with prospect tower.

T.—Memento mori—Lawn surrounded by foliage, for busts of celebrated botanists and scientific men.

U.—Grand walk, with wide borders on each side, for the scientific arrangement of the plants.

V.—Belt of trees and shrubs surrounding the gardens.

W. W. W.—Ornamental residences for the officers of the establishment.

X. X. X.—Covered seats.

Y.—Statues, vases, sun dials, and other works of art.

Z.—Exit town gate.

a.—Road round the gardens, called the Inner Drive, or Circle.

b.—Road to Colosseum, &c.

c.—Road over the bridge to Marylebone Church, &c.

*** The several ornamental buildings will be devoted to study, refreshment, and amusement.

CONTRACTS.

GLASGOW and PAISLEY JOINT RAILWAY.—Contracts for Blocks and Rails.—The Committee of Management of the above line will meet at their office, 13, Gordon Street, on Thursday, October 4th, to receive TENDERS for 10,000 STONE BLOCKS, a description of which may be seen at the office, or will be sent to parties applying for it. Also, for 500 tons of MALLEABLE IRON RAILS, and 200 tons of Cast-Iron Chairs, agreeably to specifications, which may be seen at the office, or will be sent to parties applying for it. The Directors do not bind themselves to accept the lowest offer.

By order, (Signed) MARK HUISH, J. H. HUMPHREYS, } Secretaries.

Railway Office, 13, Gordon Street, Glasgow, Sept. 20.

LONDON and BRIGHTON RAILWAY.—Wood Sleepers and Stone Blocks Wanted.—The Directors of the London and Brighton Railway Company will receive TENDERS, up to the 11th of October, for a supply of Oak, Elm, Beech, Dantzic, Memel, or Riga Sawn Sleepers, nine feet long, ten inches wide, by five inches thick; also for Sleepers formed by a cut down a round piece of Beech, Larch, or Scotch Fir, nine feet long, averaging eleven inches diameter, but not less than ten inches diameter at the smallest end, free from bark.

The Directors will also receive Tenders up to the 11th of October next, for a supply of Stone Blocks, of Bramley Fall, Heddon, Whitehouse, or Roach Portland Stone, or Guernsey Granite, each block to be two feet square and one foot thick.

No Tender will be received for less than 1,000 Wood Sleepers or 5,000 Stone Blocks. Tenders to be addressed to the Directors of the London and Brighton Railway Company, 10, Angel Court, Throgmorton Street, London. Further particulars may be obtained on application to John U. Rastrick, Civil Engineer, 451, Charing Cross East, London.

JOHN HARMAN, Chairman.

London, Sept. 13.

CHELTENHAM and GREAT WESTERN UNION RAILWAY COMPANY.—CONTRACT for WORKS.—Notice is hereby given, That the Directors will meet at their Office, in Cirencester, on Tuesday, the 16th of October, at Twelve o'Clock, to receive Tenders for the following works:—

CONTRACT No. 1, Cirencester Division.—The excavation and formation of all the earthwork, and the construction of all bridges, culverts, and other masonry, and the entire completion (except the laying of the permanent rails) of that portion of the Cirencester branch extending from a point within a field marked 29 in the Parliamentary plan, in the parish of Cirencester, to the road No. 7, near the Windmill, in the parish of Kemble, being a distance of about three miles and seventy chains.

CONTRACT No. 2, Cirencester Division.—The excavation and formation of all the earthwork, and the construction of all bridges, culverts, and other brickwork and masonry, and the entire completion (except the laying of the permanent rails) of that portion of the main line, extending from a point at or near to the proposed junction with the Cirencester branch, in a field marked No. 2, in the parish of Kemble, to a point in the field marked No. 38, in the parish of Minety, being a distance of about four miles and ten chains.

Plans and Specifications of the above works may now be seen, and printed forms of Tender obtained, at the Railway Office at Cirencester.

The Directors do not consider themselves bound to accept the lowest Tender, and they expect the parties to attend at the Office, at One o'Clock, on Tuesday, the 16th of October.

A. MERRICK, Secretary.

Cirencester, 11th September, 1838.

CAST IRON WORK.

SEWERS'-OFFICE, Guildhall, 11th of September, 1838.—To Ironfounders and others.—The Commissioners of Sewers of the city of London and liberties thereof hereby give notice, that they will meet in the Guildhall of the said city, on Tuesday, the 9th day of October next, at 11 o'clock in the forenoon, to receive TENDERS for SUPPLYING the said Commissioners with CAST-IRON WORK for the term of three years, to commence on the 31st day of December, 1838, and to terminate on the 31st day of December, 1841. A specification may be seen on application at this office. The Commissioners do not engage to accept the lowest tender. Security will be required for the due performance of the contract. No tender will be received after 12 o'clock on the day of treaty.

JOSEPH DAW, jun., Principal Clerk.

TO ARCHITECTS, BUILDERS, PLUMBERS, and the PUBLIC.—WETTERSTEDT'S PATENT METAL.—This metal having been proved by extensive experience the best and most economical covering yet discovered for every description of roofing, the Patentees now offer it with increased confidence to the public. Manufactured only and sold wholesale by Young, Dowson, and Co., at their copper and metal works, Limehouse, from whom orders will receive immediate attention. Every sheet bears the stamp of "Baron Wetterstedt's Patent Marine Metal—Young, Dowson, and Co., Limehouse, sole manufacturers." A liberal allowance to exporters, plumbers, and all large consumers.

Just published in royal 8vo., Price £1 1s.

AN ATTEMPT TO DEVELOPE THE LAW OF STORMS, by means of Facts, arranged according to place and time; and hence to point out a Cause for the VARIABLE WINDS, with the view to practical use in Navigation. Illustrated by Charts and Wood Cuts.

By Lieut.-Colonel W. REID, C.B. (of the Royal Engineers).

Published by JOHN WEALE, 59, High Holborn.

This day is published, price 3s. 6d., small folio. No 1 of

DESIGNS for SEPULCHRAL MONUMENTS by CARL TOTTIE Esq., Architect; containing a Series of highly finished Engravings on Copper, with descriptive Letter Press, for the use of those engaged in the erection of Monuments, or concerned in the improvement of Cemeteries. To be continued regularly on the 1st of every Month. A few Copies may be had on India paper, price 7s.

J. W. Rumsey, No. 6, Wellington St. Strand.

NELSON'S MONUMENT.

TO ARCHITECTS, SCULPTORS, &c. Just published, A CORRECT DETAILED PLAN OF TRAFALGAR SQUARE, with Sections, shewing the various levels of the ground, also the heights of the portico of the National Gallery, and the diameters of the various columns to the buildings composing the Square, accurately laid down from measurements, as an assistance to competitors in proportioning their designs agreeably to that site.

To be had of the Author, H. Courtney, 69, Coleshill Street, Eaton Square; Mr. Cheffin, 9, Southampton Buildings, Chancery Lane; and Mr. Weale, 59, High Holborn.

Price Five Shillings.

A SERIES OF LITHOGRAPHIC DRAWINGS, comprising Landscapes, Scenes, and Portraits, illustrative of the Native Inhabitants and Islands of NEW ZEALAND, consisting of ten plates, price 1*l.* 5s. coloured, and 18s. plain. Lithographed and Published by R. MARTIN, 26, Long Acre.

R. MARTIN'S LITHOGRAPHED FAC-SIMILE of HOLLAR'S FOUR SHEET VIEW of LONDON in 1647. Size, 7 feet 8 inches, by 1 foot 6 inches. Price 10s. And,

R. MARTIN'S SPECIMEN of LITHOGRAPHY; designed to illustrate the Capabilities of the Art. On Imperial Quarto, price 2s. 6d. May be obtained at the office, 26, Long Acre, where Drawings, Maps, Plans, Circulars, &c., are executed with expedition.

A VIEW of THE WHARNCLIFFE VIADUCT, near Hanwell, Middlesex. And

A VIEW of THE AVON BRIDGE, near the City of Bristol, both on the Line of THE GREAT WESTERN RAILWAY, are ready for delivery to subscribers, price 5s. each. Lithographed from the designs of J. K. Brunel, Esq., by R. Martin, 26, Long Acre.

LITHOGRAPHIC GERMAN STONES, of the best quality, from post 8vo. size to that of double elephant, supplied at Martin's Lithographic Establishment, 26, Long Acre. Price 4d. per lb.; 1*l.* 12s. 6d. per cwt.; or 28*l.* per ton.

LITHOGRAPHIC PRESSES, and every material used in the art, supplied, and warranted of the best description.

THE REPERTORY of PATENT INVENTIONS, No. 58, for October, price 3s., contains Specifications of the following Patents, with Engravings, viz.:—

Filton and Collier's, for power looms.
Elliot's, for the manufacture of covered buttons.
Cottam's, for wheels for railway and other carriages.
Garton's, for presses.
Losh's, for decomposing muriate of soda.
Bynner's, for lamps.
Ward's, for drums.
Greenwood and Keene's, for the manufacture of cement, and the application to the producing ornamental surfaces.
Stole's, for making sugar from sugar-cane.
List of New Patents.

London: J. S. Hodson, 112, Fleet Street.

THE MINING JOURNAL AND COMMERCIAL GAZETTE is the only Newspaper exclusively devoted to Geology, Mineralogy, and Metallurgy; combining therewith Reports of the Proceedings of Public Companies, Correspondence from the English and Foreign Mining Districts, Sales and Purchases of Ores, Prices of Shares in Mines, Railways, Joint-Stock Banks, Canals, &c., with Parliamentary Summary, London Gazette, and much original and interesting Scientific Intelligence, &c.; forming an invaluable record of every occurrence relating to

MINES, RAILWAYS, JOINT-STOCK BANKS, &c.

To which is now added (gratis) monthly,

THE MINING REVIEW,

AS A SUPPLEMENT,

containing, as heretofore, Original Articles, Reviews of Scientific Works, Foreign Extracts, Proceedings of Scientific Bodies, and Miscellaneous Intelligence.

The MINING REVIEW is also published monthly, price Sixpence, in a wrapper.

*The MINING JOURNAL is published at Two o'clock every Saturday afternoon, at the office, 12, Gough-square, Fleet-street, London, price Sixpence, and may be had of all booksellers and newsvenders in town and country.

BENNETT'S SCIENTIFIC AND MECHANICAL WORKS.

I. Bennett's Pocket Director for Millwrights and Engineers. Price 3s. 6d.

II. Bennett's Pocket Director for Carpenters, Builders, and Joiners. 4s.

III. Bennett's Pocket Director for Bricklayers, Masons, and Plasterers. 3s.

IV. Bennett's Pocket Director for Painters, Plumbers, and Glaziers. 3s. 6d.

"Four useful works."—Loudon's Architectural Mag.

V. Bennett's Arcanum of Practicable Geometry, 8vo., with 166 engraved Problems. 16s.

VI. Bennett's Artificers' Lexicon. Second Edition, 8vo. 15s.

VII. Bennett's Original Geometrical Illustrations. 4to., with 55 Plates. 21s.

VIII. Bennett's Labour Prices for Builders, &c., 8vo. 4s.

"The public are highly indebted to Mr. Bennett for his many valuable works."—Mechanic.

"The Artificers' Lexicon is likely to prove of extensive utility."—Mechanics' Magazine.

"Geometrical Illustrations well deserves a place in the library of every mechanic."—Architectural Magazine.

All by JOHN BENNETT, Engineer, &c.

Published at No. 4, Three Tun-passage, 25-26, Newgate-street; Simpkin and Co.; Whittaker and Co.; Sherwood and Co.; and Mr. Weale, Architectural Library; and all booksellers.

Of whom may be had,

Billington's Architectural Director. Second Edition, with 80 fine Engravings, 8vo., 28s.; or in 11 Parts, at 2s. 6d. each.

"A work of standard reputation."—Mechanic's Mag.

☞ Bennett's Catalogue of nearly 6,000 old and new Book is also ready.

TO NOBLEMEN, GENTLEMEN, HORTICULTURALISTS, &c.

Just published, in 8vo., price 2s. 6d., illustrated with 26 Engravings,

A PRACTICAL TREATISE on the MATERIALS used in the Construction of Hothouses, Conservatories, and other Horticultural Buildings; and on the various modes of heating such erections, made during 15 years' experience in her Majesty's Royal Botanic Garden, Kew, &c., and as head gardener to the Duke of Northumberland, at Syon House.

By J. THOMSON,

Landscape Gardener, and Hothouse Designer, and Inventor of the Improved Oval Wrought-iron Boiler for heating Conservatories, Hothouses, Churches, and all other Buildings.

Address, J. Thompson, Nurseryman and Landscape Gardener, Croydon, Surrey.

London: Richard Groombridge, No. 6, Panyer-alley, Paternoster Row.

LAXTON'S IMPROVED BUILDERS' PRICE BOOK for 1839, price 4s.; containing upwards of 8,000 Prices and 2,000 Memorandums.—A new Edition, corrected and revised throughout, will be published in November next. A great variety of new and important Tables and Memoranda connected with Building will be added.

The Author will feel obliged for any suggestions for the improvement of the forthcoming Edition; also for the price and particulars of any new inventions connected with Building.—Advertisements will be inserted at the end of the work.

11, Parliament-street, Westminster.

Office, 26, Lombard Street, London.
Manufactory, Upper Road, Deptford, Kent.

TO ARTISTS, ARCHITECTS, SURVEYORS, and ENGINEERS. WILLIAM DAY, of No. 12, Middle Row, Holborn, begs to invite the attention of the public, and of professional gentlemen in particular, to his SUPERFINE DRAWING PENCILS, which he can with confidence recommend, as being superior to most and inferior to none that have hitherto been offered for sale. Particular care has been taken in selecting the finest Cumberland Lead, and in tempering it to the various degrees of hardness, so as to suit the Pencils to the multiplied purposes for which they are required in the present advanced state of pencil drawing.

Also his SUPERFINE WATER COLOURS, in whole, half, and quarter cakes, at very reduced prices; these are manufactured of the choicest materials, are exquisitely ground, and the Colours are warranted pure and durable.

The Colours have the impress, W. Day, Holborn; the Pencils, W. Day, 12, Middle Row, Holborn, without which none are genuine.

IRON HURDLES and IMPROVED BAR and WIRE FENCES.—The strongest and cheapest description of WROUGHT-IRON PARK and FIELD FENCE, may be seen, fixed in the ground, at J. PORTER'S MANUFACTORY, 82, Upper Thames Street, between London and Southwark Bridges, and nearly opposite Dowgate-hill, leading from the Mansion-house. The superiority of the Improved Bar Fence to hurdles is acknowledged by many gentlemen in the neighbourhood of London, to whom reference can be given.—Gates, Strained Wire Fence, Hare and Rabbit Proof Fence, Garden Bordering, Flower Stands, Trainers and Arches for Garden Walls, Doorways, Seats, &c., of various sorts and patterns.—Fire-proof Doors, Safes, Chests, Cash and Deed Boxes, &c.; Iron Bedsteads for Home purposes and for Exportation.

, The Trade supplied.

GARDENS OF THE ROYAL BOTANIC SOCIETY IN THE REGENT'S PARK,

With a Plan.

Notwithstanding the manifest importance of a proper acquaintance with the productions of the vegetable kingdom, there is not, to this day, in the metropolis of the commercial world, a public establishment devoted to their general study; and while foreign countries possess such institutions, and there are forty in our own empire, we are the last to avail ourselves of their advantages. The benefits to be derived from a properly-directed botanic garden are so apparent that it argues an inconceivable deficiency in our local administration that they should be so long neglected. The only way in which the study of botany has received attention has been for medical purposes; and it is to be regretted that that knowledge should be considered as restricted to one profession, which is capable of still farther developement. The chemical properties of plants are not confined to their medical uses, but exercise important functions in manufactures; and indeed, when it is considered how little advanced is our acquaintance with their analysis, they should acquire a greater importance in our eyes, from their susceptibility of extended application in a more advanced state of science. The use of dye plants is but one of many chemical preparations; and the manufacture of sugar is a series of chemical processes. The employment of vegetable productions in textile fabrics makes them an object of commercial importance, and renders them deserving of scientific investigation; and the manufacturing properties of plants are so various as at once to open a wide field for observation and inculcate the necessity of it.

But if the study of the raw material have met with so little attention at our hands, there is another application of it to manufactures which has necessarily suffered still more in the general neglect. This is the application of the study of the external form of plants to the improvement of our arts and manufactures; and we need not be surprised if the effect of such neglect has been to leave them in a state of barbarism, as compared with the rest of Europe, unworthy of our position in the commercial world. Few points could be selected more strongly to show the intimate connexion which exists between all departments of the arts and sciences, and the ill effects which proceed from the non-cultivation of any of the series. In this case a complicated neglect is involved; and we find an equal want of attention to botany, the fine arts, and our true commercial interests. The consequence is, not only are we deprived of foreign markets, but we are unable to preserve our own from the inroads of strangers, and are subjected to the stigma of barbarism in the eyes of those to whose taste we are made captive by our own ignorance. The extent of this economical injury is twofold; first, as we are subjected to a positive loss by the importation of silks, cottons, velvets, papers, and jewellery, from France; clocks from Switzerland; bronzes from Italy; and Berlin ware from Prussia; but we contingently lose by our exclusion from foreign markets, which our other advantages would enable us to supply. The United States would undoubtedly prove a large customer for articles of taste, were we able to supply them with such productions, for which the congeniality of associations between the two nations would obtain a preference over any foreign rivals.

The adaptation of botanical subjects is the principal source of patterns for textile and imitative goods, and a facility for studying such objects is consequently the desideratum for the improvement of our manufac- tures. This has been recognised by every public body by which it has been investigated; and the evidence before the Select Committee of the House of Commons, on the State of Arts and Manufactures, affords abundant testimony of the necessity of this study.

Sir Charles Cockerell, the architect of the Bank, says—"As regards porcelain, foreigners are superior to the English in flower painting and ornamental scroll work."

Mr. George Rennie, the sculptor, attributes the excellence of the French artists to their superior facilities for studying design, and particularly recommends instruction in botanical drawing.

Mr. Crabb, an eminent fancy designer, says—"The French papers are superior in design, both in the original idea and the detail of the drawing; for in England we have no school to obtain such instruction. The foliage is beautiful and the flower borders are exceedingly well executed, while in the English patterns the leaves are not those of the flower, an inaccuracy which we never find in the French. This facility of adapting the forms and colours most gratifying to the eye, must be the result of early and continued acquaintance with flowers and plants. A botanical garden would be of the highest value, for there is scarcely anything where, in some form, botany is not introduced, and the more extensively we are acquainted with it the better; we get more beautiful lines, more original effects, and finer forms than we do by any other means; we find no colouring equal to that of nature."

Mr. Donaldson, the architect, says that the manufacturing artists require instruction, "in botany, as connected with construction, in order to give a workman an insight into the nature and properties of vegetable substances, and a more accurate knowledge of their forms when he wishes to delineate or model them; all which may be very much derived from the study of their growth and formation. I should also recommend, that such a general idea of chemistry, as connected with construction, should be given, as would enable a workman very usefully to apply that knowledge in respect to dry rot, and other similar circumstances, such as the various properties of colours, both mineral and vegetable, and their greater or less durability."

Mr. D. R. Hay, of Edinburgh, an able writer on the subject, gives testimony to the following effect:—"The vegetable kingdom presents the best examples for study, and a taste for ornamental design is not only to be acquired from the rare productions of the botanic garden, but both grace and elegance of form are to be found in the common dock, the thistle, the fern, or even in a stalk of barley. When students come to examine the ornamental remains of Athens and Rome, they will find themselves familiar with the source from which such designs were derived, for the ancients undoubtedly owed their excellence in ornamental art to the study of nature. Dr. Ure attributes the excellence of the French to the pursuit of art through the medium of nature."

The Chancellor of the Exchequer recently expressed himself in the House of Commons to the following effect:—"He thought it a disgrace to this country, possessing, as it did, so many colonies, and such vast means of collecting botanical specimens from all parts of the earth, that it should be without an extensive botanical garden, for the benefit of medical students and other scientific persons."

While the importance of botanical study is such in the lower walks of art, it is not of less necessity in its higher and more unequivocal branches. The delineation of the flower has in all countries afforded many fine paintings, a branch in which ladies have been particularly successful, and in which it was the pride of Rubens to excel equally as in the other departments of art. In all that relates to decoration, however, its application is of primary importance. Foliage is the basis of the arabesques of Pompei, and those of Giulio Romano; and, while an increasing inclination is exhibited for these styles among the patrons of art, the only true source of their power should not be neglected. The details of architecture have, even in the severest nations, derived their origin from this source, and the palm leaf of the Temple, and the lotus of Egypt, were not less favourite with their respective admirers than the variegated foliaged ornaments of the Greeks. These latter, in the acanthus and the honeysuckle, found a harmony and beauty which they made productive of the greatest effect, while the Gothic architects, in the profusion of their architectural enrichments, displayed even greater variety and research.

Although we, who are the most important commercial nation of the world, have been thus negligent in our metropolis, foreign nations, to whom botany is of far less pecuniary interest, have not been unmindful of encouraging its study. Whether for medical purposes, or for those purely scientific, or on a more extended scale, there is scarcely a town in Europe without its botanic garden, and the extent of these establishments, and the efficiency of some of them, is enough to cast shame on the negligence we have hitherto displayed. The garden at Padua appears to have been the first established in Europe, and was founded in the early part of the sixteenth century, and shortly after others were formed at Pisa, Florence, and Bologna. Since that period the progress has been such, that there is hardly a city in Italy without its botanic garden, although considerable difficulty is felt there on account of the necessity of supplying water by expensive irrigation. The Dutch early cultivated this department, and from the garden of Amsterdam sup-

plied the coffee plant, from which all those in the French colonies have been propagated. In France, the first establishment of this kind was formed at Montpelier in 1597; but, by far the best known, and the most important in Europe, is that of the Jardin des Plantes at Paris, founded in 1610. This institution merits particular notice, especially as it is a central one, and has long enjoyed the benefit of a regular administration. Its objects are twofold: first, to collect useful or remarkable plants from every part of the world, and to distribute them, as far as practicable, to every part of France, and to other countries; and, secondly, to form a school of botany and vegetable culture. Plants are brought to the garden from all countries by a universal correspondence; by particular naturalists, sent out at the expense of the nation; and by the general protection of the government, which allows entrance, free of duty, and generally carriage, free of expense, to all plants brought for the use of the garden, by whatever kind of vessel. Plants received in Paris are propagated without loss of time, and distributed to all the botanic gardens in France, and to such of the colonies where they may be useful; and, lastly, they are sent to foreign correspondents in return for similar favours. The provincial botanic gardens, of which there is at least one in every department, distribute them again among the eminent proprietors and cultivators in their neighbourhood. Instruction is given by lectures, to which the public are admitted, and by practical demonstrations. In Germany, botanic gardens are attached to every university, and in Austria the science has met with the greatest encouragement from the enlightened munificence of the sovereigns, who have neglected no opportunity of sending exploratory expeditions to collect plants. The garden at Berlin is esteemed the first in Germany. Those at Munich displays equal taste with the other foundations of the king of Bavaria. In Saxony and Wirtemberg are admired gardens; and this latter country possesses a private society of subscribers, of £1 each, for sending out travellers to collect plants in every part of Europe. In Switzerland there is a botanic garden in every canton. In Sweden, the establishment at Upsal is celebrated as having been under the direction of Linnæus. In Russia, the botanic garden of St. Petersburgh, containing sixty acres, is one of the largest in Europe, and is maintained with a munificence worthy of the scientific patronage of that empire. A considerable part of it is devoted to the cultivation of medicinal plants for the hospitals; and it is a central establishment for the use of the empire. In Spain, among others, is that of Madrid, containing forty-two acres, which, like the great garden of St. Petersburgh, cultivates medicinal plants. There are numerous other gardens in different parts of the world, as will be seen by reference to the statistical table annexed.

In our colonies the foundation of botanical gardens has been an object of government solicitude; nor has private enterprise been neglectful in promoting them in our own country. The two universities, Oxford and Cambridge, have botanical gardens; so also have Birmingham, Liverpool, Sheffield, Manchester, Leeds, Hull, Bury St. Edmunds, and Colchester; and they have been recently established at Cheltenham and Newcastle-upon-Tyne. In Scotland there are gardens at Edinburgh and Glasgow. In Ireland, at Dublin, is one belonging to Trinity College, and the splendid establishment at Glasnevin, of the Dublin Society; there are others at Cork and Belfast.

Having referred to the progress on the continent, and in our provinces, we shall in examining what has been done in the neighbourhood of the metropolis, find that there is sufficient encouragement to induce us to supply the deficiency. At Chelsea is a small garden of three acres, founded in the 17th century, and given in 1721, by Sir Hans Sloane, to the Apothecaries' Company, and devoted by them to the study of medicine, and of which they now contemplate the abandonment, if they can obtain a more suitable locality. Those at Kew have obtained considerable reputation, but are at too great a distance to be available to the great mass of the metropolitan population, while their system of management is far from being adequate to the requisites of a national institution.

That the public mind is prepared to support a botanic garden is evident by the progress of botany in every department. The number of scientific societies and floricultural exhibitions are proofs in themselves of the tendency of popular taste, while a greater developement is daily given to the culture of this science in the Zoological and public gardens, and cemeteries. As cultivators of the picturesque beauties of plants we stand in the highest position; and the English style in the decoration of gardens is that which is most prevalent on the continent, and most approved, while we stand in an eminent position with regard to the scientific study of botany by our authors and expeditions of discovery.

With such acknowledged advantages to be derived from the establishment of a botanic garden, and with such a tendency of public taste, it would appear surprising that such an object should have hitherto been neglected. This deficiency is now, however, to be supplied, and in such a manner as, it is to be hoped, will satisfy every votary of science. Although previous abortive attempts had been made to effect this object, the merit of it rests with several members of the Linnæan Society, whose success confers equal honor on the society by which it was promoted and on their enlightened exertions. On the suggestion of this undertaking, it was immediately supported by many nobleman and gentlemen, of every shade of politics, promoters of science, arts and manufactures, and they concurred in the propriety of requesting the assistance of Government. The inner circle of the Regent's Park being about to be vacated, they signed a memorial to her Majesty's Commissioners of Woods and Forests, requesting them to appropriate this site for such a laudable object. It confers the highest honour on this Administration, and on the members of her Majesty's Government, and is a high proof of their desire to encourage science, that they instantly acquiesced in the propriety of devoting the ground for these purposes to a public society, instead of making it the object of individual speculation. On this concession, a farther application was made for the patronage of Her Majesty and the Duchess of Kent; and, it is needless to say, that it was given with a generosity worthy of the illustrious personages and of the great public object concerned.

The names of the supporters of this society are a strong guarantee of its proper management, and we are happy to say that their expressed intentions are a good augury of the success of the institution. Its scientific objects are intended to be carried on in a manner commensurate with the dignity of the country, while it devotes an express attention to the encouragement of cultivation, arts, and manufactures. Public utility is the best guarantee of its success, and its promoters may feel assured, that keeping this object in view will always ensure it support. Even if a taste for such an institution did not exist, it is always the effect of well-directed efforts to create it; and how far these may be successful, we see in the impulse which is given to mechanical science by the Royal Gallery of Science and the Polytechnic Institution, which are absolutely creations of the last ten years, within which period botanical studies have acquired a still greater impulse.

The society will be constituted similarly to other scientific societies, and will be under the management of a president and council, and composed of fellows and members. It will, doubtless, be incorporated by Royal Charter, and its importance can hardly fail to obtain for it great influence; while the manner in which it is regarded by the Linnæan, Horticultural, and Botanical Societies, does honour to their enlightened liberality, and to the cause of science.

The site chosen is the inner circle of the Regent's Park, now occupied as Jenkins' nursery ground; its extent exceeds eighteen acres. That its position is eligible is best proved by referring to the neighbouring grounds of the Zoological Society, while its size is fully competent for the purposes intended. Many eminent gardens contain only three acres, while few exceed twenty, and where they do they are employed either in the cultivation of medicinal plants for the hospitals, or in the growth of fruit for the market. Its appropriation will be no encroachment on public enjoyments, while, if properly directed, it cannot fail to confer great advantage on the whole empire.

The artistical details of the plan, as shown in the accompanying drawing, are formed upon an observance of the most enlightened principles, and it has been the endeavour, in this department and in others, to make science and art equally conducive to the improvement of popular taste. This portion of the subject is deserving of particular attention, as it is by what is presented to the public eye that they will be induced to judge of the merits of the remainder. However interesting a mere planted surface might prove to the man of science, something more is requisite to the mere discursive visitant, and particularly to by far the greater proportion of its supporters, those who seek recreation rather than instruction. In fact, a due attention to objects of taste is imperative in an institution which must derive its chief support from the ladies, who are some of the most munificent patrons of this branch of science. We are but too apt to depreciate the moral effect of the pleasures of sight, although, it must be averred, most unphilosophically; for if it be allowed generally that that organ produces the most powerful impressions on the mind by its representations, so the influence exerted by it is susceptible of modifications, according to the nature of the objects presented to it. If the parks and gardens be the lungs

of the metropolis, their functions are but inadequately employed if they supply only pure air, without affording a means of exercise, for the sick man will die in the healthful shades of Montpelier or Madeira as easily as in the densest miasma; but the true means of securing the health of our population is by promoting the moral as well as the physical influence of exercise. The more interesting the garden be made, the more will its moral capabilities be augmented, and the effect of a well arranged establishment cannot fail to be of importance in restoring the tone of mind to the worn out senator, languid beauty, or over-worked citizen; for the mind requires its sustenance as well as the body, and there are as few maladies to be cured by abstinence from mental food as there are from corporeal. Such an effect cannot fail to be accompanied with an appreciation of the scientific advantages, and the attractions of such an institution might be made productive of the happiest results, in creating in the infant mind a taste for scientific pursuits.

The arrangement of this portion of the objects of the society has been confided to an architect possessing considerable taste and judgment in laying out ornamental grounds; and it is needless to say that he has complied with the utmost expectations of the enlightened promoters of the society. The geographical and physical distribution of plants is to be preserved as much as possible, and a necessary accessary is the application of national architecture in the buildings devoted to the production of individual countries. Other artistical decorations, as statues and vases, will also be employed as far as possible; and it is saying much in praise of the objects of the society, that only in this department, without going into any unnecessary expense, they may powerfully contribute to the cultivation of public taste. While the several ornamental edifices will present a synopsis of the various styles of architecture, a proper selection of statues and vases would afford all the benefit of a gallery or museum. This would give the public an opportunity of becoming acquainted with the best production of the several schools, and the elucidation of this object should be by no means omitted in the catalogue of the gardens. The selections might include casts of the several styles of Egyptian art, and of the finest ancient and modern specimens of the several Greek, Italian, French, and English schools. Whether these are classed in the general catalogue, or formed into a separate volume, the descriptions should contain sufficient information of the works and their artists, and the base of every figure should have inscribed the name of the artist, and date and style of the work.

The plants are to be arranged according to the two great systems of classification, the artificial and the natural; and will likewise be disposed in such a manner as may be useful to every class of botanist. The artificial system, or that of Linnæus, founded on the visible organs of plants, while it presents great facilities of reference, is too loose for any strict classification, and resembles the old method of animal arrangement, which in its definition of quadrupeds included in the same class of animals reptiles, and excluded cetaceæ. The natural system, formed by Jussieu, is founded upon the constitutional differences of plants, and establishes as clear a distinction between the several classes, as in animal tribes the distinction between warm and cold-blooded. The adoption of this latter system is of almost universal preference in all continental gardens founded upon improved principles, and is well calculated, by its introduction here to impress the student with the importance of studying the organic constitution of plants.

The circle is proposed to be distributed into compartments, for the reception of the several plants indigenous to Europe, Asia, Africa, America, Australia, and the Polar Regions. These again are proposed to be subdivided into gardens, in illustration of the style of ornamental gardens of the several countries of the great divisions.

At the entrance of the grounds from the grand drive leading from the Colosseum a building will be erected, devoted to the general business of the Society, and containing a library, museum, and rooms for study. The library will consist of botanical works and periodicals, and to it will be annexed a reading-room for the use of fellows and members. The museum will contain dried specimens, drawings, and engravings of recent plants, and specimens of fossils, and it would augment the value of these latter if they were accompanied by such recent plants as are identical to them, or have the nearest relation. It will farther contain illustrations of the application of vegetable productions to manufactures, as, for instance, specimens of cotton from the raw material up to its formation into cloth. The rooms for instruction will afford facilities for students to draw plants from the living objects, and it will include a convenient lecture hall, in which courses will be given similar to those which are so popular at the Jardin des Plantes at Paris, and the Royal Dublin Society's gardens at Glasnevin. From this edifice a raised viaduct promenade, overlooking a considerable portion of the gardens, will lead to a domed conservatory in the centre of the gardens. This conservatory will be on a very large scale, so as to emulate some of the foreign houses, and to give every facility for the growth of the more magnificent tropical plants. Descending from the conservatory to the right of the grand promenade, we [illegible] a garden laid out in the Dutch style, with a fountain in the centre, and canals. Beyond this will be a rosary, consisting of a circular lawn, surrounded by arched trellis-work and borders, for the growth of every variety of this queen of flowers. From this we enter the Italian garden, laid out with statues, fountains, and raised terraces, at one end of which will be a conservatory and at the other a casino. Having passed under the promenade, we reach the medico-botanical garden, adjoining the central conservatory, and surrounded by hothouses, stoves, &c. We are now at the head of the lake, which will extend for about a quarter of a mile, interspersed with islands and winding amid varied scenery. Here will be cultivated aquatic plants, and there will also be provided a salt-water basin for marine algæ. At the head of the lake will be an artificial rock for the cultivation of rock-plants, and which will contain a large reservoir to supply the several fountains and hydraulic works. The borders of the lake will, if possible, be so arranged as to display representations of natural geological sections, which may be made equally productive of interest and delight. A few of these sections would illustrate all the strata, from the primary upwards, and some of them, as the Alum Bay coast, with its variegated sands glittering in the sun, form highly beautiful objects. Mr. Niven, the superintendent of the Dublin gardens, proposed the exhibition of strata, with their appropriate plants growing on them; and this, where practicable, would certainly be of considerable interest. Around the shores of this lake will be arranged every variety of architecture, and on its borders will be seen the pointed arch of the Spanish Moor, and its kindred styles, the Turkish and the Persian kiosk, while by the side of these latter may be exhibited models of those interesting monuments, the Persepolitan remains. Farther on, the style of the Hindoo will again claim affinity with the pointed works of the Moor and the Goth, and the better known style of the Chinese will appear with its many-roofed pagoda. Between the lake and the central conservatory will be an extensive lawn, upon which ornamental shrubs and parterres of flowers will be displayed in the modern English style. In its special department will be a garden devoted, like that at Glasgow, to the cultivation of plants used in manufactures; and the dyer may here see the material of his tints, or the weaver the cotton from which his cloth is spun. In proper situations will be the American or bog-earth grounds; a fungi ground, shaded by trees, and containing stumps and roots of trees for the preservation of fungi; and tunnels and caves for the growth of mosses, ferns, fungi, and other vasculares. Around the whole ground is to be a walk with wide borders for the arrangement of plants in scientific order. By the sides of the walks raised receptacles may be placed, so as to bring some of the more delicate bog-earth plants nearer the eye.

An experimental garden may be rendered an important and interesting object, whether devoted to agriculture or manufactures. Professor Daubeny has devoted a portion of the limited space of the garden at Oxford to a series of experiments on the powers of agricultural plants, by which he endeavours to ascertain how long a plant will continue in constant cultivation before it exhausts the soil, and when one plant has exhausted the soil, what other will grow in its place. The rotation of crops, the subject of this examination, is one of the most important principles of modern agriculture, and one which greatly demands enlightened study.

By these several departments every facility will be given for the study of botany to whatever class of student may be desirous of availing himself of it; and one of the most important objects, the application of botanical productions to arts and manufactures, is particularly provided for. As far as means will permit, exertions will be made to promote the cultivation of such plants as may be most useful for these purposes, and to extend them in our own country and our colonies; and even if the society should do nothing locally, they have it in their power to further these objects, by giving prizes, as is done by the Society of Arts. To give every inducement for its local study, public botanical exhibitions will be opened periodically, in which an important feature will be introduced, by giving prizes for any new application of plants to manufactures, and for the best delineation of them, or combination in a pattern. It is gratifying to perceive that it is the intention of the society to act like the institutions at Paris and St. Petersburgh, as a central establishment, to form a union with provincial societies, and to afford every assistance to them and to individuals in the propagation of new plants.

The most effective way to render the gardens of advantage to the public is to devote great attention to everything that can promote its utility, and the simpler and more effective all its arrangements are made the more it will effect this end. A very important object is the placing the names of the plants near them in a conspicuous position, and such description should contain their scientific and common names, their country, and what are their economical uses. The catalogue should be as extensive and cheap as possible, and contain, in addition to the history of the plant and its particular uses, a chemical analysis of its several constituents; to this work should be prefixed a short explanation of botanical terms and the rudiments of the systems. Another necessary feature should be always, as far as possible, to accompany the description and the catalogue by analysis of the several soils in which the plants are placed, as this would call public attention to a department of science which is highly important, and in which, notwithstanding the efforts of Kirwan and Davy, we are still greatly deficient.

Having thus exhibited the general features of this plan, it is hardly necessary to augur its success, as that cannot fail to attend an object of such great interest and utility. We have sufficient evidence in the taste for floriculture, and the increasing cultivation of zoological and botanical science, that the public mind is sufficiently prepared for such an institution, and is perfectly capable of appreciating and supporting it; and if we wanted an instance of popular discrimination on this subject, we have a most admirable instance in the case at Dublin. The gardens of the Royal Dublin Society having been much neglected, gradually declined in public estimation; but, in 1834, no sooner was an improved system adopted, than the lectures were crowded, and the number of visitors increased, in four years, from 7,000 to 20,000. That no improvement is lost on the public mind, we see again in the effect produced by the new regulations in the national collections in London, where every change for the better has produced a corresponding increase in the number of visitants.

In conclusion, the managers have but to follow in the course they have commenced, and the success of their institution will reflect equal lustre on themselves and advantage on their country, and redeem the honour of the giant metropolis from the deficiency of such an important embellishment. Its promoters may rest assured that it is only by enlightened management that these objects are to be obtained, while through it the enjoyments of their fellow-countrymen may be promoted, and the greatest advantages conferred on the arts, sciences, commerce, and manufactures of their native land.

We have annexed a statistical account of all the principal botanic gardens in the United Kingdom and throughout the world, to show their relative size, number of species cultivated in them, their system of classification, and to what purposes they are adapted.

STATISTICS OF VARIOUS FOREIGN AND COLONIAL BOTANIC GARDENS.

NAME.	Date of Foundation.	Size in Acres.	No. of Species.	System of Classification.	Purposes.
Leyden (A)	1557	7	8,000	—	Sc. M.
Brussels	—	—	2,000	N.	Sc.
Ghent	1800	3	7,000	A.	M.
Paris (B)	1610	—	7,000	N.	Sc. M. C.
Montpelier	1597		4,000	N.	—
Rouen	—	2	—	N.	—
Spire (C)	—	—	5,000	—	—
Ratisbon	—	1	Few.	A.	M.
Carlsruhe	1715	—	7,000	—	—
Munich (D)	—	—	3,000	A.	—
Cologne (E)	—	—	4,000	—	—
Copenhagen (F)	1600	5	8,000	A.	M.
Upsal	1657	8	8,000	A.	M.
Lund	1740	2½	2,300	A.	M.
Christiana (G)	1812	7½	—	A.	—
St. Petersburgh (H)	1824	60	11,000	N. & G.	Sc. M. C.
Dorpat	—	—	14,535	—	M.
Warsaw	—	15	10,000	N.	—
Madrid (I)	1755	42	6,000	—	Sc. M. C.
Cadiz	—	3	Few.	—	M.
	—	2	—	—	C.
Valencia	1790	27	—	—	—
Barcelona (J)	1790	30	—	A.	C.
Muchamiel	—	—	2,000	—	—
Penacerrada	1818	—	2,500	—	—
Lisbon	—	2	—	—	—
Cape of Good Hope (K)	1700	19	—	G.	C.
Bourbon	—	14	5,000	N.	C.
Calcutta	—	—	3,500	—	C.
New York (L)	1800	20	4,000	—	C.
Rio Janeiro	1809	50	—	None.	C.

(A) Four acres are devoted to a medical garden.
(B) The Paris garden is also devoted to zoology, and the annual outlay is 12,000*l.*
(C) The number of plants at Spire is 24,000.
(D) At Munich is another garden.
(E) At Vienna are several botanic gardens.
(F) The income at Copenhagen is 685*l.* per annum, and at Lund 50*l.*
(G) At Stockholm there are two gardens, one of which is attached to the Veterinary College.
(H) The cost of the St. Petersburgh garden has been 50,000*l.*, the income 10,000*l.* per annum, and the number of plants 80,000.
(I) The income is 1,900*l.* per annum.
(J) At Barcelona are two.
(K) At the Cape is another belonging to the South African Institution.
(L) The cost of the gardens at Charleston was 15,000*l.*

The columns show the name, date of foundation, size in acres, number of species cultivated, system of classification, and the purposes to which devoted. If arranged entirely according to the artificial or Linnæan system, it is expressed by the letter A; if partially, according to the natural or Jussieuan (N); if geographically (G). The purposes to which devoted express whether scientific (Sc), medical (M), horticultural (H), or for the cultivation of plants used in commerce and manufactures (C). The greater portion of the gardens in Russia and Spain is used to grow drugs for the hospitals, and those in Spain also cultivate fruit for sale. This accounts for the large size.

It will be seen by the above that the size for a general botanical garden is from 15 to 20 acres, and for a medico-botanical garden two to three acres. In most of the preceding, professors are attached and lectures are delivered.

BOTANIC GARDENS IN THE UNITED KINGDOM.

NAME.	Date.	Size.	No. of Species.	System.	Purpose.	Income.
Chelsea (A)	1650	3	—	A.	M.	
Horticultural, Chiswick (B)	—	33	—		H.	£6,500
Kew (C)	1760	—	10,000	—	Sc. H.	
Oxford (D)	1632	5	3,000	N.	Sc. M.	
Cambridge	1761	3½	9,000	—	Sc. M.	
Liverpool (E)	1801	6	6,000	—	Sc.	
Bury	1820	9	—	A.	Sc. H.	£350
Manchester (F)	1830	17	—	A.	Sc. H.	£1,443
Birmingham (G)	1831	16½	3,000	A.	Sc. H.	
Sheffield	1836	17½	—	N.	Sc. H.	£1,900
Edinburgh (H)	1680	16	5,000	A.	Sc.	
Glasgow	1817	8	9,000	N.	Sc. M. C.	
Dublin	1786	3½	5,000	N.	M.	
Do., Glasnevin	1796	16	5,000	N.	Sc. C.	£1,020

(A) Chelsea belongs to the Apothecaries' Company; it is proposed to be given up.
(B) The cost of Chiswick is 17,000*l.*
(C) Kew is supported by a government grant.
(D) Oxford and Cambridge are both endowed.
(E, F, G) Liverpool, Manchester, and Birmingham have each 500 annual subscribers. Liverpool cost 13,300*l.*, Birmingham 13,000*l.*, and Sheffield 18,562*l.*
(H) At Edinburgh are also the gardens of the Caledonian Horticultural Society, founded in 1809.
(I) The whole extent of the grounds at Glasnevin are 30 acres; they are thrown open to the public, and the lectures are also gratuitous.

The other botanical gardens are—Hull, founded in 1802; York, in 1822; Colchester; Leeds, which cost 10,000*l.*; Cheltenham, in 1837; Cork and Belfast, 1830.

Lectures are delivered at Chelsea, Oxford, Cambridge, Edinburgh, Glasgow, Dublin, Glasnevin, Cork, and Belfast.

The general outlay in establishing a botanic garden is from 15,000*l.* to 20,000*l.* The number of annual subscribers in a population of 200,000 is about 500.

Besides these 22 botanic gardens there are as many more in the other parts of the English empire, most of which are splendid establishments, supported by the colonial authorities. There are, one in America, three in the West Indies, four in Africa, eight in the East Indies, and two in Australia.

The following is an account of the collections attached to some botanical institutions. The herbarium of the British Museum is the second in the world:—

Name.	No. of Plants in Herbarium.	No. of vols. in Library.
Paris	50,000	—
Madrid	30,000	2,000
Cadiz	—	1,000
British Museum	45,000	—
Oxford	25,000	2,000
Liverpool	—	300

REVIEWS.

Papers on subjects connected with the Corps of Royal Engineers. Vol. II. 1838.

In our second number we reviewed the first volume of these Transactions, and we felt it to be our duty to express how little we thought that it was worthy of the scientific attainments of the members of that distinguished corps; our military brethren, however, have now come into the field with the second volume of their Transactions, and we are happy to bear testimony to the merits of their exertions, which keep pace with the spirit of enlightenment which prompted the work. It is evident that the march of improvement is abroad in this quarter as well as in others; and the interest taken by the engineers in the advancement of their branch of study, cannot fail to operate upon the other departments of the army. The preface to the work gives some able remarks on the importance of engineering knowledge to every officer; a fact which, we believe, is recognised in all services but in this. With our extensive sea coasts, and detached territories, it would appear to a cursory observer, of the first importance that an officer in command should be able as fully to avail himself of the physical means under his controul, as of the human or mechanical force. The editor observes very truly, that the study of fortification is not so abstruse as is believed by the generality of the profession, and that the acquisition of it may be obtained with comparatively little exertion. This is perfectly true, for to obtain a competent knowledge how to erect field works, by no means requires the extensive studies which are necessary in laying out a strong place; we believe, however, that this erroneous impression has been created very much by the engineers themselves, who by their disputes about Vauban and Belidor, the perpendicular or the circular systems, frighten the novice from a study which seems to have as many systems as writers, and to be in a more unsettled state than even cosmogony. Sound judgment has more to do with fortification than all the books that have ever been written, which, were they ten thousand, would fail in affording plans for every variety of nature. We think that a knowledge of fortification might be extended farther than to the military profession generally; for we consider that it might very advantageously form an adjunct to the studies of the civil engineer. Such a practice would greatly increase the military capabilities of the nation at large; and its advantage will be fully evident by recurring to such periods as the threatened invasion in the last French war. The efficiency of the civil engineers would in any such event be very great, as their local knowledge of the country, and their practice of dealing with it, would be equally available with their experience in the construction of works. It has been the practice of governments to deprecate military knowledge in the people; but we are far from being persuaded that in this instance it would be wise to deprive the country of such auxiliaries so important on an emergency.

Among the papers there is necessarily much that is merely military, while some are exclusively philosophic; but still the subjects which are of practical bearing on our own department are so numerous, that we can only regret that it is not in our power to avail ourselves fully of all that we should desire to lay before our readers. In the papers on mines and breaches there is much interesting matter on the destructive power of gun-powder, and particularly in that on the demolition of the Glaciere Bastion at Quebec. The memoir on the fortifications of Western Germany shows a research which is of the most laudable nature, but of which, not being in our own department, we cannot avail ourselves. A long article on contoured plans and defilades, by Lieut. Harness, is not confined in its interest to the military reader, but may be read with advantage by many others; it treats on the delineation of the surface of a country on paper, and contains many good points. The reports on the South Union and the Brighton Railways are too well known to need repetition.

The paper on the dams of the Rideau Canal, by Captain Alderson, details the different modes used, and gives an account of their failures. This paper shows that, in Canada, the government authorities have been led into the danger of following a bad American practice. Instead of the works being as in Europe planned by the Engineer, and executed from his drawings, the contractor offers a plan and estimate, according to which he proposes to do the work, and in the event of his failure, he loses his contract and money expended. It need scarcely be observed, that the effect of such arrangements is to cause repeated failures, and the least inconveniences sustained are protracted delays, and unnecessary outlay. It is well known that nothing is more dangerous than for a man to unite two trades; in fact, it is contrary to the principle of the subdivision of labour; and if, in this country, such attempts fail, we need not wonder at the inconvenience they cause in Canada. If such a system is adopted by the government, from misconceived notions of economy, we can only recommend them to look to the results, and they will find that, however a half-witted speculator may be willing to tamper with his delusions, the consequences to the authorities must be vexation, delay and disgrace.

Captain Sandham, gives some useful information respecting the formation of jetties, in a communication on the coast defences of Holland; he also advocates the advantage of building scarp walls with a curvilinear batter to sustain the action of the sea.

In a memorandum on the repair of the Brighton Chain-pier, Major Piper makes the following remarks on the lateral pressure of the wind:—

The lateral pressure on the side elevations of the bays (the vertical one being always consequent upon it) is the worst that can be received from the course of the wind; and as it appears to have been a principal cause, if not the only one, of all the hazardous movements of the superstructure, should another equally severe gale of wind take place before other checks than those which have been added be applied, it is very possible a repetition of the disaster will take place, against which every precaution should be taken. As a limit should be given to this description of dangerous motion (flexibility being necessary only to the extent of preserving the work from fracture by any sudden strain, from whatever direction), it seems therefore advisable, that every bridge or arch built upon the suspension principle, should be furnished with guide or check-chains, to counteract the effect of the pressure of the wind in a lateral direction, which should there be applied, in addition to the chain intended, to check the motion in a vertical direction.

On the 17th October (present year), the repairs having been completed, a heavy rolling (spring tide) sea,* impelled by a tremendous gale of wind from the westward, came pitching on to the shore with the flow, at the rate of nearly 16 knots; and as many of the waves, previous to their discharge, lifted to an average height of 13 feet over and above the usual high-water mark, breaking violently at intervals over the whole length of roadway, the binding chains and segments may be said not only to have had a fair trial, but to have answered their purpose; yet the constant tugging and pressure, from the effects of the wind, along the whole communication, was so great as to throw the section into a complete state of winding, giving it the appearance of being in distress; wherefore, if the pressure of the wind, in so unfavourable a direction, be taken into consideration (supposing the same to be from the flow of the scud, at a moderate calculation, about 4lb. the square foot, which it must have been,) a fair inference may be drawn as to what a work of this nature has to contend with; and as every season must also tend to weaken its foundation, as well as loosen the pile work, it is evident accidents will happen, and it is only matter of surprise they have not occurred more frequently.

Lieut.-Col. Reid contributes further observations on the moving of the shingle of the beach along the coast, and describes the nature of a great part of the coast on the British Channel. The following observation is an answer to the mistaken ideas which prevail as to the supposed great height to which waves rise:—

The observations on the effect of the waves in this paper apply to breakers on the coast, and not to undulations in deep water, for the water in them is said to have no progressive movement, but only a vertical one.

In ordinary gales of wind at Brighton, in the winter of 1836, the undulations of the waves measured twelve feet high; and they proceeded towards the shore at the rate of twelve miles an hour.

In the winter of 1837, Captain Alderson observed them, in gales rather more severe than the year before; and the waves measured 12½ feet high, and the undulations proceeded at the rate of eighteen miles an hour.

We differ in opinion from the Colonel, respecting the stopping of the progress of the shingle, as we expressed in our notice of Lieut. Worthington's work on Dover Harbour. The Colonel observes, with regard to this latter plan,—

The direction of the line of coast, with reference to the prevailing gales, seems to determine where the shingle will accumulate, or where the sea will be most likely to encroach upon the land; and seems to be one of the most important points to study, as regards the subject of opening bar-harbours.

It well deserves consideration, whether embankments (on the south coast of England) run out on the eastward of bar-harbours, in a line parallel to the line formed by nature on the east side of Portsmouth Harbour, would not lead to a similar effect as that produced there in keeping open one principal channel. By a proper system of groins on the west side of such harbours, shingle coming from the westward would be stopped, and much of the materials which now form the bars might be arrested in their course.

The slope of the beach is flatter after a southerly gale, and its average slope is about 1 foot in 9.

If groins are not carried far enough in-land, the sea in south-west storms

* The time between the rising, reach, and dispersion of each wave, was averaged by a stop-watch at 10 seconds, and the distance passed over 250 feet, giving a velocity of 17 miles per hour. Desultory waves broke heavily and with effect at 15 and 16 feet, threatening to tear up the platforms of the towers; and had the wind shifted to the south or west, with the increased send which would then have been given to the swell, the scene of last year would most likely have been repeated.

(on the south coast) will break round and insulate them. If they are not high enough at high-water mark, the gravel will be carried over them to the eastward; and if they are too short, it will pass round the outer end of them.

During southerly gales, it is frequently said, that the gravel is "carried into the sea," because the receding waves draw it down; but it is again driven back, and if the wind be south-west it is set to the eastward.

Lieut.-Col. Reid also contributes an elaborate article on hurricanes. The articles on the construction of barracks in the West Indies, are well worthy of the attention of those who devote attention to architectural hygiene. Colonel Pasley considers another department of internal economy in an examination into the modes proposed for curing smoky chimneys. He observes on Captain Sandham's plan:—

Fig. 1 represents this arrangement, and so far as the plan alone of the fire place is concerned, it does not appear to differ much from Count Rumford's system; but in fig. 2, which is the elevation, and in fig. 3, which is the section of the same, it will be observed, that not only the sides, but the upper part of the back of the fire-place also, are coved on Captain Sandham's system. Below this top coving is the mouth of the chimney, as it may be termed, being a rectangular opening, 9 inches wide and 6 inches high, above the level of the hobs of the grate, into which the smoke from the fire first enters as it rises, in a direction almost horizontal, and then changing its course, ascends vertically by the throat of the chimney into the flue. The appearance of this aperture, viewed from the room, is shown in figure 1. In some other fire places its width has been reduced to 8 inches.

Fig. 1. Plan.

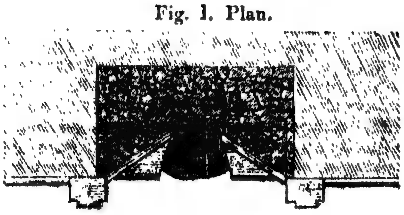


Fig. 2. Elevation.

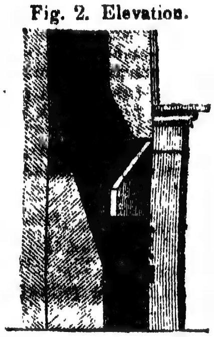

Fig. 3. Section.

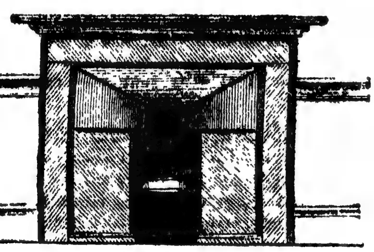

The smoke ascending through the mouth and throat of the chimney, may be compared to water flowing through a strait, leading suddenly into a sort of gulf or much larger channel; for in this fire-place, after raising the sides and back, within and behind the side covings and grate, a little higher than the mouth of the chimney, the filling in behind the side covings, as well as behind the position of the back of the grate, terminated abruptly, without being rounded off; thus, whilst the side covings were not quite so deeply recessed, at Count Rumford's, every thing else agreed with his rules, excepting that the Count had no top coving.

In Sandhamizing our fire-places in Brompton barracks, we formed our covings with paving-tiles a foot square, cut to the required splays; and one of these tiles over the centre of the throat of the chimney was made to take out, having been placed dry, and the joints towards the room not flushed, but only pointed with cement, so that it is moveable when the chimney requires sweeping.

I have already given one instance of the importance of Count Rumford's rule, "that after reducing the throat of a chimney the work should terminate abruptly a little above that level." Several other proofs of the necessity of this maxim occurred in the course of our alterations; for the bricklayers in two or three instances thought proper, of their own accord, to slope up both the back and sides, above the throats of our Sandhamized fire-places, in order to make a neater finish, and also from a natural desire to make it stronger; and thus they produced that sort of trumpet-mouth above the throat of the chimney which the Count reprobated; in consequence of which all those fire-places still continued to smoke a little; but on altering them once more, by removing all the extra filling in, so as to restore abruptly the large rectangular opening of the original brick-work, forming a sort of gulf immediately above the throat of the chimney, this evil was remedied; and none of these chimneys now smoke, even in the most violent gales of unfavourable wind, excepting by emitting small puffs occasionally on lighting the fire, which cease when it burns clear.

Of all the fire-places that have been Sandhamized properly, with due attention to the position of the grate and to the above maxim, only one still smokes in westerly winds, which is that of a servant's room in the attic story, over my office; and as the office itself has been completely cured, the difference must be ascribed to the flue in the attic story being much shorter, which always causes a tendency to smoke,

As compared with Count Rumford's system, I conceive that the top coving of Captain Sandham's improved fire-place is a great advantage, inasmuch as it brings the throat of the chimney nearer to the fire, without the inconvenience of allowing too much of the heated air to pass up the flue; instead of which it throws out much more heat into the room than when the back is upright, as every one acknowledges, who has been in the same rooms, before and after the fire-places were Sandhamized.

In relation to the improved chimneys in the Anchorsmiths' shops at Chatham, the Colonel remarks—

Captain Sandham has not yet tried his system for curing the chimneys of smoky kitchens, to which, from the space required for the cooking apparatus, it may be more difficult to apply it; but the remarkable improvement in the fire-place of the anchorsmiths' shop in her Majesty's dock-yard at Chatham, which was effected many years ago by the late Mr. Perkins, then master builder, nearly on the same principle recently adopted by Captain Sandham, gives reason to hope that it may do good even in kitchens. The large rectangular hearths, on which the anchorsmiths made the fires for heating their irons, were formerly entirely covered with very large hoods, into which the smoke was expected to rise vertically, and be discharged at the top of the flues or chimney-shafts, of which these hoods formed the bottom, instead of which the greater part of the smoke spread over and filled that large room. The improvement made by Mr. Perkins consisted in removing these hoods entirely; instead of which he built flues at the back of the several hearths, each having a rectangular opening into it a little higher than the hearth, to which it bears the same relation as the opening in the back of Captain Sandham's fire-place does to the grate. For the larger fires required for the heaviest work, these openings are about 18 inches high, and about 4 feet 6 inches wide, whilst the depth of the flue, measured from front to rear, is 2 feet in the clear; and there is only one flue of this sort in each chimney shaft. For the smaller fires, suited to light work, there are two flues to every shaft, the entrance into which measures about 15 inches high and about 2 feet broad, the depth of the flue at this part being 13 or 14 inches. The fires in the anchorsmiths' shop, made upon the several hearths, are all by this arrangement placed entirely in front of, and not under, any part of their respective flues; and yet the smoke, instead of rising vertically, and filling the whole of this spacious workshop, rushes apparently out of its natural direction into the openings at the bottom of the flue. This ingenious alteration proved so extremely beneficial, by diminishing the quantity of smoke, that the anchorsmiths addressed a letter of thanks to Mr. Perkins, signed by the whole of them, in which they declared, that they were convinced that it might be the means of prolonging their lives.

The concluding observation affords a full reply to many triflers, who would be rather inclined to treat such a subject as a matter of ridicule, than to recognise the importance of any thing which affects human health. At the end of the volume, Lieutenant Denison, the Editor, contributes an account of experiments, which he modestly styles "Notes on Concrete," to which we intend to refer on a subsequent occasion. Captain Alderson supplies a memorandum on paving stables, which is highly deserving of attention, and it would be productive of much benefit if his brother officers were to communicate in the same manner the different modes of construction which fall under their notice.

Having given such an extensive view of the work, it [illegible] unnecessary for us to dilate upon its merits; we leave it to our readers to speak for itself, and can only say that it reflects equal credit upon the spirit and intelligence of its supporters.

Guide Pittoresque de Paris à Saint Germain par le Chemin de Fer. With Maps and Plates. Paris, 1837: Didot. 8vo., 20 pp., price 5d.

Notice Historique sur St. Germain en Laye, Itineraire par le Chemin de Fer. Paris, 1838: Bocquet. 24mo., 140 pp., price 6d.

We have thought proper to notice these works, as some people like to know how they do these things in France. The St. Germain railway created a greater sensation at Paris than our Greenwich line did here; and a proof of the interest taken in it is afforded by the circumstance that one of the first booksellers in France thought it worth his while to publish a work on the subject.

Both these works are necessarily on a small scale, and are cheap. They contain the usual quantity of topographical matter, and give a history of railway communication elsewhere. The first is preferable for the care with which it is got up, while the second work is a genuine French production, full of magniloquence, and the joint essay of two literators.

From them we learn that the St. Germain line was sanctioned by the legislature on the 9th July, 1835, and was opened on the 25th August, 1837; that it is eleven miles and three-quarters long, and conveys 3,000 passengers on week days, and 18,000 on Sundays.

A Dictionary of Arts, Manufactures, and Mines. By ANDREW URE, M.D. London: Longman, 1838. Part II.

We have now to lay before our readers our observations on the Second Number of this valuable compilation. A considerable part of it is occupied with the articles on bleaching, dyeing, and printing, which give a great deal of useful English and foreign information on the subject; it strikes us, however, that more details could have been given as to the French black dyes.

After giving an account of the several economical applications of bitumen or asphalte, and of its several localities, to which might have been added Neufchatel, the following detail is given :—

Bituminous mastic, or cement, has been of late extensively employed in France for covering roofs and terraces, and lining water cisterns. The mineral bitumen used for the composition of this mastic is procured chiefly from the Obsann (Bas-Rhin) [query, Lobsan], from the Parc (department de l'Ain), and from the Puy-de-la-Poix (department of Puy-de-Dome). But boiled coal-tar answers equally well. In the neighbourhood of these localities there is a limestone impregnated with bitumen, which suits for giving consistence to the cement. This is well-dried, ground to powder, sifted, and stirred while hot in about one-fifth its weight of melted asphaltum, contained in a cast-iron boiler. Dry chalk or bricks, ground and sifted, will suit equally well. As soon as this paste is made quite homogeneous, it is lifted out with an iron shovel or spoon, and spread in rectangular moulds, secured with pegs at the joints, fastened to a kind of platform of smoothed planks, covered with strong sheet-iron. The sides of these moulds should be previously smeared over with a thin coat of loam paste, to prevent their adhesion to the mastic. Whenever the cake is cold, the frame is taken asunder, and it is removed from the iron plate by an oblong shovel, or strong spatula of iron. These cakes or bricks are usually 18 inches long, 12 broad, and 4 thick, and weigh about 70lbs.

The article on blocks is highly interesting, as it describes the several processes adopted in the manufacture by Brunel's automatic machinery in Portsmouth dockyard.

The article devoted to bones, will be found deserving of the attention of our chemical friends, as it points out a strong case of the mechanical operations of chemistry in the difference between bone black and vegetable charcoal, the former, although equally a carbonate, possessing greater purifying power from its property of taking lime in solution. There are also some good remarks in it on substitutes for charcoal.

The interesting account of bookbinding does not range itself among our class of subjects, but we can recommend to the notice of our readers the articles on brass and bronze; under the latter head the following processes are communicated :—

Statues, vases, bas-reliefs, and other objects made of gypsum, may be durably bronzed, and bear exposure to the weather better than after the ordinary oil varnish, by the following process :—Prepare a soap from linseed oil, boiled with caustic soda lye, to which add a solution of common salt, and concentrate it by boiling, till it becomes somewhat granular on the surface. It is then thrown upon a piece of linen cloth, and strained with moderate pressure. What passes through is to be diluted with boiling water, and again filtered. On the other hand, four parts of blue vitriol and one part of copperas are to be dissolved separately in hot water. This solution is to be poured slowly into the solution of soap, as long as it occasions any precipitate. This flocculent matter is a mixture of cupreous soap and ferruginous soap, that is, a combination of the oxides of copper and iron with the margaric acid of the soda soap. The copper soap is green, the iron soap is reddish brown, and both together resemble that green rust which is characteristic of the antique bronzes. When the precipitate is completely separated, a fresh portion of the vitriol solution is to be poured upon it in a copper pan, and is made to boil, in order to wash it. After some time the liquid part must be decanted, and replaced by warm water for the purpose of washing the metallic soaps. They are finally treated with cold water, pressed in a linen bag, drained and dried. In this state the compound is ready for use in the following way :—

Three pounds of pure linseed oil are to be boiled with twelve ounces of finely-powdered litharge, then strained through a coarse canvas cloth, and allowed to stand in a warm place till the soap turns clear. Fifteen ounces of this soap-varnish, mixed with 12 ounces of the above metallic soaps, and five ounces of fine white wax, are to be melted together at a gentle heat in a porcelain basin, by means of a water bath. The mixture must be kept for some time in a melted state, to expel any moisture which it may contain. It must be then applied, by means of a painter's brush, to the surface of the gypsum previously heated to the temperature of about 200 deg. F. By skilful management of the heat, the colour may be evenly and smoothly laid on without filling up the minute lineaments of the busts. When, after remaining in the cool air for a few days, the smell of the pigment has gone off, the surface is to be rubbed with cotton wool, or a fine linen rag, and variegated with a few streaks of metal powder or shell gold. Small objects may be dipped in the melted mixture, and then exposed to the heat of a fire till they are thoroughly penetrated and evenly coated with it.

In the long and valuable treatise on bread, we are surprised that no notice is given of the *grano duro* or other wheats of Sicily, which possess superior qualities, and are so extensively employed in the manufacture of macaroni and ot[illegible] productions.

Under the head of Bricks, although there is a pretty long account of the subject, we notice the omission of several late improvements—as those of the Marquis of Tweedale, Smart, and others. It strikes us, too, that there must be some error in the statement of the French brickmakers moulding 9 or 10,000 bricks in a day, and a discrepancy as to two or three inches of breeze being laid between each layer of bricks to be burned in the clamps.

The account of the button manufacture we find approved even in Birmingham; but although it relates several ingenious mechanical processes, it does not lie exactly within our domain.

There is a valuable article on chain cables, from which we wish we could extract at greater length. We must observe that, in stating the invention of Captain Brown, it should be noticed, that although he was then in the merchant service, he is also a commander in the Royal Navy.

Strength of iron cables compared with hemp cables :—

Iron Cables. Diameter of Iron Rod.	Hemp Cables. Circumference of Rope.	Resistance.
Inches.	*Inches.*	*Tons.*
$0\frac{7}{8}$	9	12
1	10	18
$1\frac{1}{8}$	11	26
$1\frac{1}{4}$	12	32
$1\frac{5}{16}$	13	35
$1\frac{3}{8}$	14 to 15	38
$1\frac{1}{2}$	16	44
$1\frac{5}{8}$	17	52
$1\frac{3}{4}$	18	60
$1\frac{7}{8}$	20	70
2	22 to 24	80

It would be imprudent to put hemp cables to severer strains than those indicated in the preceding table, drawn up from Brunton's experiments; but the iron cables of the above sizes will support a double strain without breaking. They ought never, in common cases, however, to be exposed to a greater stress. A cable destined for ships of a certain tonnage, should not be employed in those of greater burden. Thus treated it may be always trusted to do its duty, and will last longer than the ship to which it belongs. A considerable part of this decided superiority which iron cables have over hemp ones, is undoubtedly due to the admirable form contrived by Brunton. Repeated experiments have proved that his cables possess double the strength of the iron rods with which they are made—a fact which demonstrates that no stronger form can be devised or is in fact possible.

Vessels furnished with such cables have been saved by them from the most imminent peril. The Henry, sent out with army stores during the Peninsular war, was caught on the northern coast of Spain in a furious storm. She ran for shelter into the Bay of Biscay among the rocks, where she was exposed for three days to the hurricane. She possessed fortunately one of Brunton's 70 fathom chain cables, which held good all the time, but it was found afterwards to have had the links of its lower portion polished bright by attrition against the rocky bottom. A hemp cable would have been speedily torn to pieces in such a predicament.

In the contracts of the Admiralty for chain cables for the British navy, it is stipulated that "the iron shall have been manufactured in the best manner from pig iron, smelted from iron-stone only, and selected of the best quality for the purpose, and shall not have received in any process whatever subsequent to the smelting, the admixture of either the cinder or oxides produced in the manufacture of iron; and shall also have been puddled in the best manner upon iron bottoms, and at least three times sufficiently drawn out at three distinct welding heats, and at least twice properly fagotted."

The following is a table of the breaking proof of chain cables, and of the iron for the purpose of making them, also of the proofs required by her Majesty's navy for chains :—

Size of Bolt.	Proof of Bolt.		Proof of Chain.		Navy Proof of Chain.
Inches.	*Tons.*	*Cwt.*	*Tons.*	*Cwt.*	*Tons.*
$\frac{1}{2}$	5	7	8	11	$4\frac{1}{2}$
$\frac{5}{8}$	8	7	13	4	$5\frac{1}{2}$
$\frac{3}{4}$	12	1	19	5	$10\frac{7}{8}$
$\frac{7}{8}$	16	4	26	5	$13\frac{3}{4}$
1	21	8	34	5	18
$1\frac{1}{8}$	27	2	48	15	$22\frac{3}{4}$
$1\frac{1}{4}$	[illegible]	10	53	11	$28\frac{1}{8}$
$1\frac{3}{8}$	40	10	65	0	34
$1\frac{1}{2}$	48	4	77	0	$40\frac{1}{2}$
$1\frac{5}{8}$	56	11	90	10	$47\frac{1}{2}$
$1\frac{3}{4}$	65	12	105	0	$55\frac{1}{8}$
$1\frac{7}{8}$	75	6	120	10	$63\frac{1}{4}$
2	85	14	137	0	72
$2\frac{1}{8}$	96	15	155	0	$81\frac{1}{4}$

In Brunton's cable the matter in the link is thrown very much into one plane; the link being of an oval form, and provided with a stay. As there are emergencies in which the cable must be severed, this is accomplished in those of iron by means of a bolt and sheckle (shackle), at every fathom or two fathoms; so that by striking out this bolt or pin, this cable is parted with more ease than a hempen one can be cut.

The [illegible] will [illegible] the [illegible] view of the Second

Number, that the work still maintains its interest, and promises to preserve throughout the valuable character which we have felt happy to acknowledge.

A Practical Treatise on the Construction of Stoves, and other Horticultural Buildings, and on the Principles of Heat, as applied to Hothouses, Conservatories, and other Horticultural Erections. By J. W. Thompson, Nurseryman, &c., 8vo., with wood engravings. London: Groombridge.

We took occasion last month to give a general view of this work, but on account of the press of matter had not time to get the wood cuts prepared, illustrative of some extracts we proposed to make, and consequently deferred them until the present occasion.

The subjoined account of the works at the Duke of Northumberland's, cannot fail to prove interesting to our practical readers; and those who wish to refer to Mr. Thompson's comparison of the merits of wood and iron roofs, will find it given at p. 24 of the Journal, in a communication to us:—

Notwithstanding, however, that the result of my observations and calculations are unfavourable to iron roofs, I am willing to admit that for lightness and neatness of appearance in the structure, iron has and always will have the advantage; in fact, it would be almost impossible without iron to erect such magnificent conservatories as those of the Duke of Northumberland at Syon House.

Fig. 1.—Elevation of Syon Conservatory.

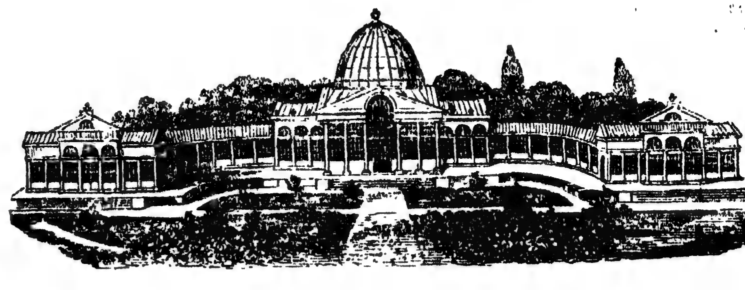

Fig. 2.—Ground Plan of the Conservatory at Syon House, showing the arrangement of the Steam Boilers, Pipes, &c.

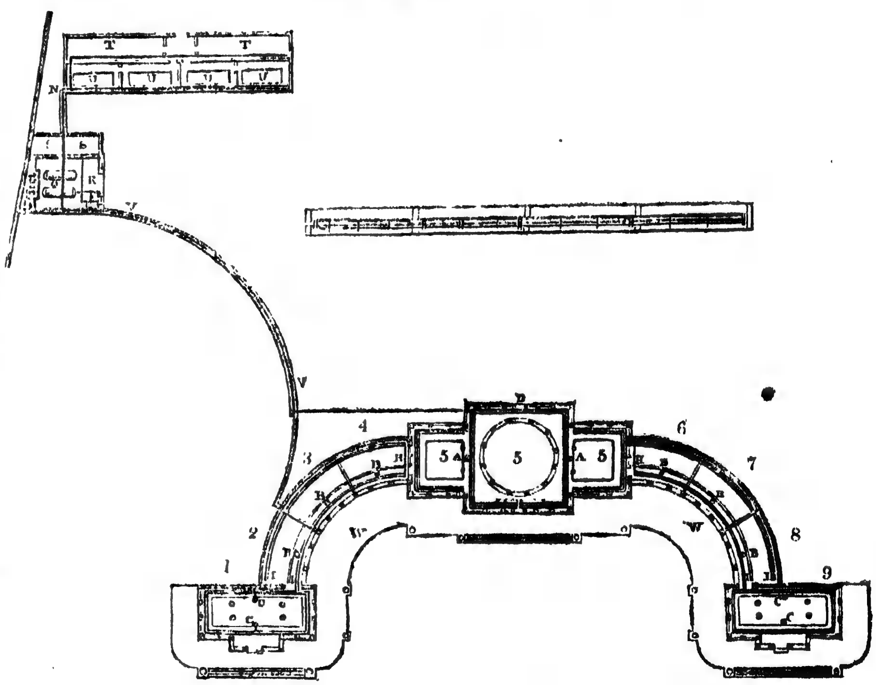

Fig. 1 and 2. Elevation and plan of the conservatory, showing the arrangement of the plant houses, the boiler house, the steam boilers, and pipes for heating the various erections designed and executed by C. Fowler, Esq. The interior arrangement of the houses for the culture of the various genera and species of plants, was planned by his Grace as well as the design for the tasteful flower garden in front of the conservatory, and were executed from his Grace's own drawings. The entire length of the range of houses is nearly 600 feet; the centre represented by a glass dome, see fig. 1., is about 65 feet high, divided as follows:—

1. Camelia house. 2. Geraniums, and other plants of similar habit. 3. New Holland, and other hardwooded species. 4. Delicate stove plants grown in pots, and plunged in bark beds. 5.5.5. Is a stove a hundred feet long for the growth of large trees, such as cocoa nuts, and other lofty fastgrowing tropical plants, which are planted out in beds of properly prepared earth, and some of them are now nearly forty feet high, particularly the Flate palm, presented to his Grace by Lord Tankerville, about six years ago. 6. Delicate stove plants grown in pots, and plunged in bark beds. 7. A choice collection of heaths, and other hardwooded Cape plants. 8. Miscellaneous collection. 9. The Orange house. A.A Vapour valve. for steaming the houses. BB. CC. Similar, but smaller valves, for the same purpose; the centre division has seventeen four-inch cast iron pipes below the paths, all round the four sides of the division. The steam enters from the main at D, and the condensed water passes off at E. The two square divisions adjoining the central one have fourteen four-inch pipes round three sides each. The steam enters at F.F., and the condensed water passes off at G.G. The first curved division on either side of the centre has six pipes each at the front, and six at the back. The steam at the main pipe enters at H.H. The other curved divisions have five pipes in the front and four at the back of each division; the condensed water escapes at I.I.I.I., the end divisions forming the extreme wings of the range, have eight pipes, all round, branching each way from the end of the main at K.K., and deliver the condensed water at L.L. M. Pipe for warming the back sheds. N. Main entering propagating pipes; condensed water passes off at O. P. Chimney divided into four, these to cut the column of smoke. Q. The two steam boilers for heating the houses. R. The boiler house. S. Coal sheds. T. Potting sheds. U. Four propagating or nursing pits. V. The main steam pipe from the boilers enveloped in saw dust, a non-conductor of heat; while passing along a hollow wall into the culvert, and entering the range at the centre or domed house. W. Terrace walk.

At the end of the middle walk of the botanic garden, as shown in the annexed perspective view of the range of houses, is placed a large ornamental basin and fountain, supplied from a pure spring, which rises about a mile and a half from the garden. At the back of the propagating house, as shown in the ground plan, fig. 1., is a row of sheds, the entire length of the propagating edifices, which are heated by a steam pipe, and used for holding plants in pots during the cold winter and spring months.

Mr. Thompson afterwards communicates an interesting account of the elegant conservatory of Lord Ashburton, at the Grange, in Hampshire.

The dimensions of this conservatory are eighty feet in length, forty-six feet wide, and twenty-one feet high, and it was designed and executed by Sir Charles R. Cockerell. The situation of this spacious area is adjoining to the ladies' apartments, the windows of which are directed towards the conservatory. This building is complete both with regard to architectural and horticultural proportions, two important points in similar structures, but seldom attended to, or not with a due regard to the various bearings of situation and circumstances. It is, in my opinion, one of the best buildings of the kind that I have seen either in this country, or on the continent.

Fig. 1.—Elevation of Conservatory at the Grange, Hampshire.

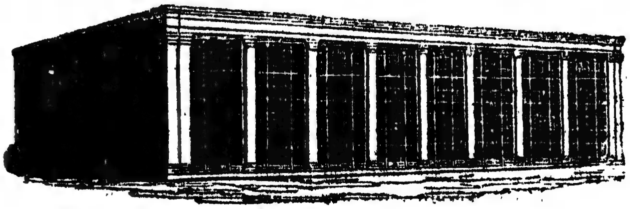

Fig. 2.—Interior View.

Fig. 3.—Section of Conservatory.

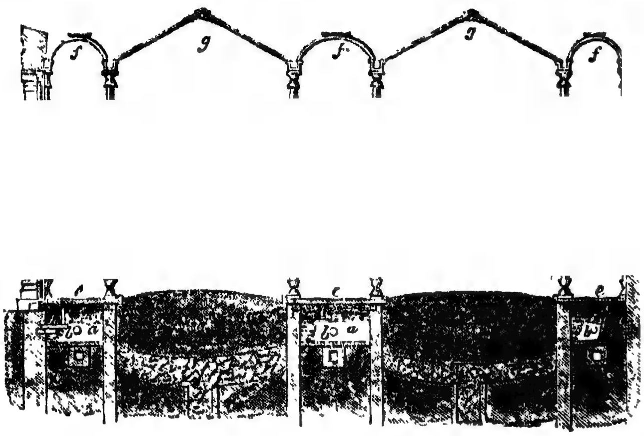

Fig. 4.—Parts of Column at Large.

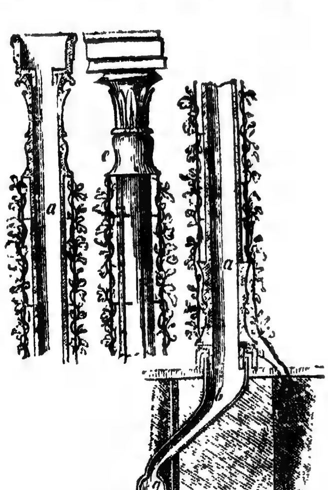

A glance at the annexed diagram, which represents a section, will at once show how easy it would be, where expense is a secondary consideration, to vary the plan of a greenhouse or conservatory according to the extent of ground, and to have an exotic garden in which perpetual spring could be maintained. The roof, which in this example is double, and which might be continued to any extent, is supported by cast iron hollow columns, *a a*, which also carry off the water that falls on the roof, into drains, properly placed for its reception, as at *g*, and which, after supplying an immense reservoir under ground for the supply of the house, as well as for use in the event of fire, or any other scarcity of water, discharge the remainder beyond the limits of the building. These columns are ornamented with mouldings, and have wires fastened to them, for the purpose of training creeping plants. The side walks *e e*, are four feet nine inches broad, and the centre and principal one *c*, six feet and a half. These walks are covered with an arched roof, formed of double plates of rolled iron *f f f*, between which is left a space of two inches, confining a stratum of air, to prevent the escape of heat, or the admission of cold. Over these plates are placed an iron grating for a safe walk, to enable the operatives to repair the glass, give air, &c. This house was heated by Mr. Sylvester, with steam, the pipes being placed under the walks, as at *b b b*, and the cavity *a a*, served as a reservoir for containing heated air, which was admitted into the house as required.

The two steam boilers were removed, about seven years ago, in consequence of the great quantity of fuel consumed to generate sufficient steam to heat the conservatory, which is now done with hot water.

Iron is indispensable in such extensive erections as those at Sion House and the Grange, Bretton Hall, Yorkshire, the seat of T. W. Beaumont, Esq., or the splendid structures for plants at Alton Towers, the princely residence of the Earl of Shrewsbury, now only eclipsed by Sion: and that now erecting by the Duke of Devonshire at Chatsworth, which, when finished, will surpass every thing of the kind. In such stupendous structures, without the introduction of iron for rafters, columns, and other supporters, the depth and thickness of wood rafters, &c., necessary in such buildings would give them a very dark, gloomy, and heavy appearance; but then much of that evil which I complain of as arising from iron, might be obviated by having the sides of the lights made of wood, and the sash bars of copper, with small rollers affixed to the underside of the lights to make them run easily, but under no pretence should iron be used for forcing houses in pits, nor for small greenhouses or conservatories. I may, indeed, repeat that the use of cast iron for horticultural buildings can only be justified in such extreme cases as in those to which I have alluded. I feel fully confident that if proper attention were paid to the construction of hot houses, and to the materials used in their erection, that the appearance of a wood-roofed house would not be altogether objectionable. For the assistance of persons building houses for horticultural purposes, who may have had less practical experience than myself, I will proceed here to give a brief description of such materials, and modes of construction as I think will combine the whole of the desired objects.

The first thing to be attended to is, to give the roof a proper pitch or inclination, so as effectually to carry off the water and prevent the drip in the house, which is highly injurious to plants grown in pots. Secondly, to form the roof in the following manner: the rafters to be of wood, varying according to the length of the roof from five to eleven inches deep, the section of it to be wedge-shaped from three to four inches in the upper, and about half an inch wide on the under side, the ends and sides of the lights to be made of wood, the top from four to five inches, the sides two inches and a quarter, and the bottom from six to seven inches wide. The sash bars to prevent as much as possible the obstruction of the sun's rays should be of copper, which will give the house a light and neat appearance, and yet not subject the plants to the injurious extremes of temperature, as the small quantity of metal in the thin sash bars, which need not be more than half an inch wide and about the same depth, will cause but very little variation in the temperature by radiation, and suffer little from expansion and contraction. Neither would it increase the expense of the light in any great degree over one made of wood; for as copper of those dimensions would not weigh more than six or eight ounces to the lineal or running foot, I should suppose it could be bought for about 1s. 6d. per lb., the expense, therefore, would be trifling when compared with the advantages; indeed, the extra expense would be repaid in a few years by the saving of wood in repairing the lights, as glaziers cannot hack out old putty without destroying the sash bars, and this being frequently done, when lights are kept constantly in use, very soon lessens the substance.

I therefore recommend all persons when erecting forcing and other houses to have them constructed of the above materials, particularly if they are desirous of excelling in the culture of fruits and plants, as by the use of copper sash bars, they obtain all the desired objects—namely, lightness of appearance, and economy of fuel, glass, and labour. I should further suggest that every gentleman before erecting, or deciding on any particular plan or dimensions for a house or houses for horticultural purposes, should consult his own gardener, or some other practical man acquainted with the subject, as it is impossible for any architect or surveyor, unless directed by, and in conjunction with, the experienced gardener, to know the proper dimensions and elevations of a hot house to answer all the purposes to which it is appropriated so well as the gardener.

We again take the opportunity of expressing our satisfaction with Mr. Thompson's work, and of recommending it to the notice of our readers.

The History and Description of the London and Birmingham Railway. Part III. By Thomas Roscoe, assisted in the Historical Information by Peter Lecount, Esq., F.R.A.S. (Civil Engineer). London: Charles Tilt. Birmingham: Wrightson and Webb.

The third part of this interesting work contains three beautiful engravings—one, the entrance to the railway at Birmingham; the second, a view of the Sherborne Viaduct; and the third, a view of Harrow-on-the-Hill. The letter-press proceeds with a description of the works from the Harrow Station to the Linslade Tunnel, interspersed with an historial account of the towns and villages on each side of the line. The works near Watford show the vast extent of the cuttings and embankments, also the difficulties that are encountered in the formation of railway.

Here the first appearance of the chalk formation is seen, and being mixed with flint and gravel was found highly advantageous in forming the road. This soil was conveyed to and partly formed the embankment which passes by the town of Watford, and carries the railway across the Colne valley. It took nearly one million cubic yards of earth to make this embankment, which is in some places above forty feet in height, and is the largest throughout the whole line. Soon after entering upon it the railway goes over the London road, by a brick viaduct of five arches, of forty-three feet span each; they are composed of ellipses, having voussoirs at the intrados; the centre arch is of an oblique form, in order that the course of the road should be preserved as heretofore. This may be thought a bad feature in a design of this kind, but it was unavoidable, the trustees having compulsory clauses in the Act of Parliament to compel the Company to adopt this form of arch. The manner in which the engineer has overcome the defect in the design is admirable, and it is scarcely perceptible to the observer: it is a very massive structure, and cost in its erection £9,700. The other arches are square with the line of railway; and at either end are retaining walls built into the embankment, making the total length of the viaduct three hundred and seventy feet.

The next bridge conveys the railway over the river Colne. It consists of five semicircular brick arches, of thirty feet span each, with side walls, and having a stone cornice its whole length, the total length of the parapet walls being 312 feet. It has a light appearance; and viewed from the meadows appears very lofty, being fifty feet high. The construction of this bridge was a work of considerable skill and labour, the foundations being of the loosest material possible; in fact, it may almost be called a floating bridge—for it rests entirely on platforms of wood, having sheet piling to protect them. The cost of its construction was little less than £10,000. The whole of the land near this spot is most precarious in stability; and the effects are clearly visible in the amazing "slips" which have taken place in the embankment across the valley. Oftentimes, in a very few hours, the level of the newly formed ground has sunk several feet, while the base of the embankment has widened out to an enormous extent, causing infinite labour to bring the level of the railway back again to its original state, and to make it solid enough for the passage of the trains, this has caused many a sleepless night to the workmen and engineers. The length of this embankment is about a mile and a half, and is composed entirely of the finest materials for such a purpose—chalk and gravel.

Near the station at Box Moor there are some bridges well worthy the notice and study of the engineer.

Within a few yards of the Station, the Railway crosses by a bridge of one arch over the London road, at an angle of thirty two degrees. This bridge will amply repay the engineer, or man of science, for the trouble of a personal inspection; and we will endeavour to describe it to such of our readers as are unable to visit it.

The science of bridge building has, of late years, made rapid strides towards perfection, and there are many instances where arches of immense span have been erected; but we believe no example exists of such an oblique arch executed in brick work as that now under notice. The square span across the road is twenty one feet; but the obliquity causes the span on the face of the arch to be lengthened to more than thirty nine feet: its facial form is that of a flat segment of a circle; and the acute angle of the quoins is chamfered off until it reaches the obtuse angle, where it vanishes. This gives the bridge the appearance of having one voussoir more than it really has; and also obviates the defects which generally attend the construction of skew bridges, by the acute angles of the quoins being broken off or injured, either by settlement or accidental blows. The idea of cutting off the acute angles of such arches emanated, we believe, from Mr. George Buck, the resident engineer of the line from London to Tring. The perfect manner in which the whole of the stone work, and the spiral courses of the bricks, are executed, reflects great credit upon the builders, Messrs. Cubitt, of London.

Holebrook's Patent Propelling Machinery.

A pamphlet detailing the specification of this patent has been sent to us. The first method is a mere imitation and evident piracy of the principle of Morgan's wheel, and decidedly a worse combination; the second is a mode of shrouding the paddles of a wheel, the floats of which radiate from the centre. However valuable a good method of shrouding the paddle wheel may be, that pointed out by the patentee is decidedly the worst that could be devised. The screws and cogs of the pinions and wheels would be torn to atoms, on account of the corrosion by the sea water, if it were attempted to adjust the floats as proposed, after the wheel had been exposed 24 hours to its action.

Designs for Sepulchral Monuments. By Carl Tottie. London: Rumsey, 1838. With Plates, engraved by E. Ravenscroft (Parts 1 and 2).

These designs are, we believe, by a German architect, and represent monuments erected by him here and abroad. They do great credit to his taste, and are characterised by a chaste simplicity and elegance, appropriate to the subject proposed. The first and second, however, one Greek and the other Gothic, have rather a German scantiness: but the third is exceedingly elegant, although we a[illegible] tion the strict Hellenism of the urn. It is appropriately devoted to a young lady.

In the second part, the designs are generally of greater purity; but the application of them seems to us to be rather inappropriate. We should have felt disposed to have devoted the graver to the elderly lady, and the more ornamented to the literary gentleman. The fourth and sixth are pyramidal, which, although we consider rather of an Egyptian than of a Greek character, still are simple and elegant, without that vacancy which we characterised in the previous number. The proportions of the fifth design are almost perfect, except perhaps too great breadth in the base; but the urn and its twining foliage are unexceptionable.

We feel happy to welcome these productions, as they are calculated to do good at a time when, by the extension of cemeteries, a demand has been created for this class of external sepulchral monuments. The cemetery at Kensal Green, and that at Highgate, are fine ornaments to the metropolis, and we find that in the former a considerable demand has been created for a more elevated class of memorials of the dead. Many of the designs there are from the British Museum; but we cannot say that we equally admire the log or coffin-shaped tombs that are spread about in such abundance. Medicine seems to have erected her standard there; and the temple of Hygeia to St. John Long, and a large family tomb to puff a living hygeist, form two of the most remarkable features there.

Architektonische Mittheilungen, Von C. T. Ottmer; *Braunschweig*, C. W. Ramdohr, 1838 (*Architectural Communications* of C. T. Ottmer, Ducal Architect, Brunswick).

This work excites considerable attention in Germany, and induces us to make some remarks upon it. The author is C. T. Ottmer, who has obtained considerable reputation in Germany by his success in building the new palace at Brunswick. The work contains copperplates with letter-press, describing the new theatre at Wolfenbuttle, and giving designs for country houses.

Herr Ottmer has recently completed under the direction of the Duke of Brunswick, a theatre in the Gothic style, in the palace at Wolfenbuttle, and it is principally to the description of this, that his volume is devoted. This edifice is considered in Germany as almost the commencement of a new era, for with their rage for the classic, they had little contemplated the restoration of the Gothic, and least of all its adaptation to the temples of the muses. We believe this is the only instance of a theatre in Europe in the Gothic style, but at any rate it is the most important, and it will naturally be regarded by many of our architectural readers with considerable interest.

The architect has so far felt himself successful in the execution of his task, that, in the height of his zeal for the promotion of his newly adopted style, he adds to his work plans for country houses and residences in Gothic.

On the Construction of Walls. By S. Romberg. Vienna, 1838. (German.) 4to., with Plates.

The preceding work is a fair criterion of the attention shown by the Austrian architects to diffuse professional information. When the general low ebb of knowledge in Austria is considered, it reflects considerable credit that they should exhibit such proficiency in this art. The interest attached to the acquisition of the best foreign intelligence, by both architects and engineers, is fully shown in the architectural periodicals of Vienna, which borrow, not unfrequently, from our Journal and other English works.

M. Romberg's work is exceedingly well got up, and he has availed himself fully of the latest French and English materials. The whole is accompanied by a number of engravings, illustrative of the text.

LITERARY NOTICES.

The second part of the new edition of "Treadgold's work on the Steam Engine" (completing the work) is just published; the plates are beautifully engraved, particularly those of Stephenson's patent locomotive engines; they alone are worth the whole amount that is charged for the work. We shall not fail to notice this work in our next number.

The first part of a "Practical Treatise on the art of Bridge Building," a work much wanted, will be published by the end of the month, it will contain the drawings of several bridges erected by Rennie and other eminent engineers. The work is edited by Mr. Cresy and Mr. M'Neil, both names well known to the profession.

Mr. Foulston's work containing numerous drawings of the public buildings, erected by him in the west of England, will be published in course of the month.

ORIGINAL PAPERS, COMMUNICATIONS, &c.

ON CIVIL ENGINEERING EDUCATION, AND REWARDS.

There is nothing gives us so much pleasure as to find professional subjects the topics of public discussion, for however ignorantly they may be treated, the profession will still gain by any attention which is afforded to them. We are induced to take up the subject in consequence of a somewhat long article in the *Times*, entitled, "Civil Engineering Schools, and State of Things in England." The drift of this article is the favourite echo of the sentimental journey—they do these things better in France; and the writer, having the subject all his own way, has had no difficulty in coming to the wished-for conclusion. Now, whatever opinions we may entertain of Civil Engineering *per se*, and however much we might desire its amendment, we are prepared to maintain its relative merit; and we feel ourselves the more called upon to do it, as this lucubration gave rise to others of similar tendency in the *Athenæum* and other journals.

As it did not occur to the writer in the *Times* to look to reasons, but as he rather prefers to state matters as they appeared to him, we shall, before entering into an examination of the subject, briefly consider the statements put forth. He asserts, first of all, that in England it is boldly said that boys must be sent, if sent at all, to get their scientific education before they are fifteen years of age, because they must go into engineers' offices very shortly after. Now we must beg to inform him, that either he or his pseudo antagonists must be strangely ignorant of the subject which they are discussing, if they are not aware that in no College, where there is a class for Civil Engineering, is any one allowed to matriculate under fourteen or fifteen years of age, unless he had contemplated the enlightened Universities of Oxford and Cambridge, where, however, we believe there have been no boy bachelors since Wolsey. Having set out with this false postulate, it is no difficulty for our worthy critic to knock down the giants he himself had created; and then showing that sixteen years is the age required for entry in France, he proceeds to argue upon the absurdity of English parents and engineers requiring impossibilities, and thinking that mere children can be taught what is hard work for young men.

From this the writer gives a very minute and detailed account of all the various items of preliminary examination; but with all his care he has omitted one indispensable point, to which we beg permission to call the attention of a gentleman so critical, for it is doubtless a necessary qualification of an engineer in the eyes of our Gallic neighbours. Next he describes the severe extent of seven hours daily study during ten months of the year, before which the labours of the idle English clerk are to be considered as nought. Without giving any statement of the subjects of study, he concludes, in a style of much flippancy, by eulogising the French, and reprobating the folly of the poor English.

To have placed the subject fully before the public, it would have been well to have afforded some information as to what has been done in other places, so as to have enabled us to form a judgment upon the propriety of the course proposed to be pursued here. But the writer was probably one of that not uncommon class of English cognoscenti, who, after measuring the continent from Boulogne, and ascertaining the state of society at a provincial table *d'hôte*, are enabled dictatorially to assert the superiority of every thing that is foreign, and the insignificance of all that is English, although their ignorance upon both sides may be pretty much upon a par. He might have informed us, that the Polytechnic School is not a mere school of engineering, but educates students for the artillery, marines, army and navy, military engineering, manufactories of gunpowder and saltpetre, and for all the public situations which require an extensive knowledge of the physical and mathematical sciences. As to the preliminary examination, we will guarantee to find plenty of English boys of sixteen who will go through it with ease, however arduous it may appear in France. The subjects of study are analysis, mechanics, geodesy and topography, statistics, physics, chemistry and manipulations, architecture, French composition, and German and English. No, it would not have suited the critic to supply these facts, for he must have added to them, *proh pudor*, that this complete and unique education lasts two years—a goodly railway speed for manufacturing French civil engineers.

As we are desirous, in some degree, to supply the defect, we shall shortly describe other similar institutions. The Gewerb Institute, at Berlin, is more strictly limited to arts and manufactures; and the studies, which include those of the Polytechnic School, also embrace practical and theoretical instruction in the manufacture of machinery. At Geneva is a school principally devoted to the staple mechanical trades of the city, in which there is a good practical course of three years' study. At Stockholm also is a Technological School.

All this in the eyes of the penny-wise superficial philosophers shows the immense pre-eminence of continental nations, and our glaring inferiority. To the thinking, however, it offers an inducement to investigate the results of these different systems of management. The quantum of education is not always proportionate to the number of schools, nor is instruction solely dependent on public establishments. We should be in a low state, indeed, if our knowledge were to be measured by the system of the two great universities, where no public lectures are given, and nothing is taught but Latin and Greek. What a contrast this forms with a French or German University, or even with one in Scotland, and yet, strange to say, were lectures to be delivered at Oxford or Cambridge to-morrow, none would attend them. The English students do not turn out worse proficients than their foreign neighbours, for although they attend no public lectures, they conduct their education in another way, obtaining that by private study in books, which foreigners receive by the oral instruction of their professors. Here the enigma is solved, and we need not inquire as to who is likely to acquire the soundest information, and have the best organized mind; the one who labours for himself, or he who depends on the studies of another. Were we to compare the subjects of foreign studies with those of an English youth, we could not fail to be struck by the extent of the former and relative paucity of the latter; but the results are far different from those which are at first sight necessarily consequent on such a diversity. There is such a thing as exercising the memory at the expense of the judgment, and it is the difference between these two terms which constitutes the distinction between a foreigner and an Englishman. Whoever has witnessed the encyclopædic examination of a German or French college must have appreciated this, and seen how the student sinks when separated from the corks, which may bear him well so long as he has them at hand, but without which he cannot meet an emergency. This is particularly the case with German education, which of all others asserts the highest claim in the eyes of its votaries to be considered as a system particularly calculated to develope the mind. It is true that they furnish the mind with abundance of materials upon which to operate, but they never afford it means to exert its powers; and the system pursued may be as well expected to augment the reasoning powers, as to weigh down an infant with a heavy musket would be calculated to prepare him as a soldier. This cultivation of the judgment is the essential distinction of English education, and however faulty it may appear to some, it will be found, on investigation, that it has not rendered us worse than our neighbours, while, on the contrary, it has enabled us in most cases to be their equals, and in many instances to be their superiors.

If genius were to be taught in universities, and if science were only to be gained from the dictates of professors, we should indeed be in a miserable state of mental degradation. What, however, is our relative position? Our poetry is not only equal to that of any other nation, but we have produced the only epic poet in the sublime. Our drama has overturned the French school, and is paramount in Europe; and our literature has either been the parent of that of new nations, or supplanted the literature already existing. In the fine arts, however far we may be behind the ancients, we are certainly on a par with the moderns; while we have schools of architecture and painting which may lay claim to a superiority over those of the Continent, in the departments of copper-plate and wood engraving we are confessedly supreme. In every thing we have gone beyond the rude lessons of our masters, and there is no branch of science to which we have not contributed more than our quota; in metaphysics, in philosophy, in mathematics, in astronomy, chemistry, and geology, we can justly claim a considerable share in their progress, and in many instances we have wrought out the pure metal where we had received only the raw ore, or the refuse dross. Talk not of going to France or the Continent for instruction, but rather search through western Europe for the monuments of our mental power; from the constitution of the state, down to the very fuel on the hearth, how few things are there which have not an English origin?

Having thus considered how far national constitution must necessarily operate in causing a modification in the process of instruction, and how far the course pursued in England has contributed to the satisfaction of the objects required, let us now examine how far we shall be justified, in the particular case of civil engineering, in remodelling our present course, by the example of our French neighbours. To whatever department we direct our search it will not be very easy to find any symptoms of inferiority in the working of our present system. The French roads, independently of their wretched construction, have been for years rendered worse for want of repairs, and they are so deficient in extent that the mere outlay necessary is so considerable as to render any attempt at improvement an object of financial terror. We have not the Alps in England, but it would not

be difficult to find a parallel for the roads over Mount Cenis, and the Simplon. Canals are so rare, that commerce derives scarcely any benefit from them; and as to their engineering merits, we believe they are bounded to their being the only works of the kind in France. We are not aware that the French docks and basins are of more excellence than our's in the detail of their construction, but we know well that they are neither equal in number, extent, grandeur, or genius. The principal work as a harbour is Cherbourg, and that may look up, on the opposite coast and find many rivals. As to bridges we will willingly pit the bridges of London against those of all France, and we are not afraid of the contest when the French engineers have yet to equal the Roman remains in their own country. There are more bogs drained in Ireland than there have been in all France, and they have no embankments of land which it is necessary to put in rivalry with those of the Wash. It would be hard, perhaps, to put railways into the scale, were not the assumptions of superiority such as to render it necessary to ask what instruction we are to derive from France in that department? Why, we can tell those who think so lowly of their country, that what we have to be taught is, that the French are learning from us.

The Normal school may supply France with very excellent engineers, chemists, manufacturers, and mechanists; but we must beg leave respectfully to doubt whether this admirable system is calculated for either English or Americans, or whether we should be justified in rejecting one by which we have already gained a superiority. It is a pity, if our foreign friends do really possess such pre-eminence, that they do not come over here, for they know well that the English people are ever ready munificently to reward merit, and that they have never been swayed by any local prejudices to withhold their patronage from any one of any nation. They have not hitherto done this, and the only foreigners who have come among us have, under the highest auspices, only failed in quackery and nonsense, in cases where Englishmen had already succeeded. No, no; there is no occasion to come to England to teach us this lesson; let them go and look at the Stephenson locomotive on the St. Cloud railway, at our engines navigating their waters, and at their mines and factories, conducted by Englishmen under the shade of their high scientific attainments.

> Tityre, tu patulæ recubans sub tegmine fagi
> Sylvestrem tenui musam meditaris avenâ:
> Nos patriæ fines, et dulcia linquimus arva.

The English mechanic has no Encyclopedia of Trades to consult, no Ecole Royale to frequent, and no Conservatoire des Arts et Metiers, in which to exhibit his performances; but he can study in his own house, has his own periodicals, can learn from his brother workmen, and frequent a Mechanics' Institute in every town, while he has the free-born spirit of the English race to direct him, and the statue of Watt to remind him how his fellow-countrymen can appreciate his labours.

In repudiating the absurd assumptions of foreigners, and vindicating the merits of our own countrymen, we are far from wishing it to be understood that we are opposed to the introduction of any improvement, or wish that the profession should remain stationary. On the contrary, none can be more fully persuaded that the great source of our superiority lies in the readiness to adopt whatever is new and useful, and in carefully discarding whatever is antiquated or absurd; we cannot, however, coincide in thinking that the French university system is in the least degree suitable to the habits or exigencies of our own nation, or our brethren in the United States. We are fully disposed to hail with approbation the course proposed by the English colleges, and we think that the practice of the students attending philosophical lectures will prove an important help to their professional education, while, on the other hand, we should absolutely deprecate the idea of any attempt totally to educate them, whether in an English academy or the Ecole Polytechnique itself, which might perhaps turn out a very good surveyor's hack, but would not be very likely to produce a Smeaton, a Brindley, or a Watt.

Among other improvements which we should earnestly desire to see effected, would be a more equal distribution of loaves and fishes, as we see no reason why civil engineers should be the only unrewarded class of her Majesty's intellectual subjects. It is not that we think that yards of riband are absolutely essential to the prosperity of the profession, but because we feel that in the universal shower, mitres might be found to fit other heads than those to which they have hitherto been restricted. After the foreigner has ended his special tour to our great engineering monuments, which are the great attraction to continental visitants, he need not take very much trouble to ascertain the quantum of gratitude and honour which has fallen to the lot of the praiseworthy engineers. He may, perhaps, from the contemplation of other professions, have had his expectations raised, and he might very justly anticipate that at least something would be done for the well-deserving of their country. No *a priori* comparative calculation will, however, enable him to form anything like an estimate, for without speaking of the legal profession, he will find eight or nine artist knights—painters, sculptors, and architects; and as many baronets and a score of knights among the physicians and surgeons, besides G.C.H. and scientific honours superfluous. The architects build in brick, and therefore they are not neglected; but the engineer, because he works in earth, is to get nothing for his labour. The only knight was made so, more for a bridge, more as an architect, than an engineer. Captain Brown got his foreign cross of Hanover, partly because he had a naval title; and with the crosses of Leopold, held by the two Stephensons, ends the muster-roll of professional honours. We may perhaps consider as a dawning of a better system, that the President of the Institution of Civil Engineers has been appointed a member of the Council of the Metropolitan University; but we should desire that, if the golden shower is to be scattered, that it may come before those who have deserved it have passed from this life, or attained a period when they no longer care even for the fame of their own labours.

This neglect is certainly not of to-day, but it is one to which it is high time that a remedy should be applied. Labouring against obstacles to which no other profession is subjected, we certainly cannot think that their hard-earned pecuniary gains are anything more than a compensation for the abuse of the vulgar mob, or the bear-baiting of Parliamentary counsel; and although an Englishman's spirit will make him do his work without reward, we do not think that the dignity of the nation allows the obligations solely to lie on one side. While the living are without honour, the dead are without remembrance, and the neglect which obscures the present engineer has forgotten to commemorate his predecessor, for with the single exception of Watt, who has obtained statues more as a mechanist and a Scotchman, there is not one person connected with the profession of whom an artist has made a record, or that has a marble sculptured with his name. That the profession has not been wanting in men deserving, we appeal to Brindley and to Smeaton, who from the glories of their works may despise all other monuments, and call on their admirers to look around.

ON DESIGN.

"It is very possible that men may lose rather than gain by these; may lessen the force of their own genius by forming it upon that of others; may have less knowledge of their own, for contenting themselves with that of those before them."—ESSAY ON THE ANCIENTS AND MODERNS, by Sir W. Temple.

The little originality which is observable in the architectural constructions of the present day would almost induce one to suppose that the talent of design existed only among the ancients, and that the moderns are mere imitators. There appears to me to be too much attention paid in this age to classical models. What are our buildings in general but ill-adapted semblances of antique beauty? In what consists their originality? The Pyramids of Egypt we admire for their grandeur, the Parthenon for its elegant simplicity, and St. Peter's at Rome for its unaffected sublimity; even the Gothic cathedrals of our forefathers, confused as they appear in construction, and as diversified in ornament, delight us in their magnificence, and excite our admiration at the bold originality of their conception. There is nothing of this primitive character observable in modern buildings: a portico, minutely copied from the antique, or an Italian façade, engrosses our highest efforts in the art. Beyond these exertions of our imitative faculties we seldom rise. Our architecture, like our literature at an earlier period of our history, abounds with Latin translations and Greek roots. We slavishly adhere to the instructions of the ancients, and too frequently differ from them only to show the poverty of our intellect and the barrenness of our imaginations. It is true that by a well-directed study of classic models we may derive considerable benefit; our ideas may be enlarged and taste refined: the ignorant alone disregard knowledge which they cannot comprehend; the self-sufficient despise the efforts of their predecessors. But conceding thus much to the ancients, I must think that we err in following them too closely. Should we not rather, receiving their suggestions and duly respecting their instructions, strike out for ourselves new and better-adapted designs? At what eminence can we arrive by mere imitation? It may suit the torpidity of our inactive genius, but what glory can it achieve for us in the eyes of posterity?

If indeed we are incapable of conceiving designs ourselves, or rising over the genius of the ancients, it were well for us rather to adhere to their models than to erect our own. So far as those may guide us, they serve as standards of taste, but no farther. Too close

an attention to their beauties begets a lassitude of intellect; we admire them as Telemaque would have admired Calypso, forgetful of his own glory; we dwell upon their beauties with a slavish admiration, which weakens the power of our minds and subjugates our capacities to their tyrannous authority.

This is the age of trifling; instead of those manly and vigorous efforts of a refined natural genius, we see little but the puny exertions of a meagre and acquired taste. Architects, with few exceptions, seem fearful of putting forward the abilities with which Heaven has endowed them; sheltering their talents under the power of ancient and approved rules, they incautiously become mere copyists—"imitatores servorum pecus," and enslave their minds to the domination of antiquity.

By the study of ancient models we observe much that may reasonably be adapted to present uses. The proportion of their columns is admitted to be just and symmetrical; their mouldings in general are appropriate and elegant, their ornaments beautiful and suitable to their purpose, and the *tout en semble* of many of their buildings, as the Temple of the Ilissus, the Parthenon, and the Pantheon, fills us with admiration at the inventive genius of the noble-minded people who possessed the desire and ability to erect monuments so grand and celebrated. On the other hand, the style of their buildings cannot be wholly consistent with our country; the difference in climate, in habits, and in situation, necessarily calls for an alteration in design: what was appropriate as a mode in Greece might be ridiculous in Italy, and must be somewhat *outré* in England. The more I reflect upon our local and moral distinctions, and upon our present plagiarisms in architecture, the more I deprecate the system and lament our want of originality of thought.

Let me hope that these observations may meet the eye of those who have the genius and power of thinking and acting for themselves. Shaking from their brains "the dust of the schools," let them dare to be original in design: the ancients let them regard with the admiration due to their genius and the respect due to their authority, but not with the humility of a slave or the submission of a child.

While I behold so splendid an effort of thought as Barry's design for the new houses of Parliament, I cannot think that we want inventive genius, but must attribute its non-appearance to inactivity of mind. Architects, in the present day, "swarm like locusts on the banks of Nile," or architects in name; but how few of these undistinguished column rearers are worthy of the honours attached to the profession. To these I do not address myself, but to such only as are architects in character; them I would instigate to arouse themselves from the apathy of imitation; them, upon whose exertions much of the glory of our country depends: and if these remarks shall only excite among them the desire of originality, I shall not have written in vain. H. G.

COMPETITION DESIGNS.

"The better please, the worse displease; I aske no more."—Spencer.

We have endeavoured, in a few preceding papers, to place before our readers opinions on various architectural compositions, and the train of reasoning upon which those opinions have been formed. The criticism being under an assumed initial, our observations will be taken only for what they are worth; no great name consecrates an abuse, no insignificant one detracts from a just observation; valued only by their propriety, they can be appreciated only as they embody a true perception of the subject. Anonymous criticism on the fine arts seems, indeed, and especially in referring to very modern works, extremely desirable; for as there is no appointed judge in these matters, no Attorney-General to apply to, no Lord Chancellor to confirm a decision, a general feeling only can direct the public mind.

Even thus sheltered, it is not possible to escape personality; and although endeavouring to frame our remarks with the most scrupulous fairness, and in no case offering an opinion without citing our reasons or our authority, we have some who will cry, with the Israelites in the desert, "Who made you a judge over us?" The latter character we utterly repudiate. We are, as far as in us lies, advocates for what we think true principles, and opposers of those who violate them.

Nor are we, while condemning these violations of established rules and ancient examples, at all aware that we are therefore to be considered as upholding a system of servile imitation; nor can such a charge be borne out by any observation we have yet made. When, to avoid servile imitation, an artist starts into an absurdity,—when that his building may NOT look like a Greek one (a most desirable attempt), he deviates into increased expense and positive deformity, we would fairly ask the judgment of the few who have studied the art, and of the many who are ignorant of it, whether such deviations can be desirable.

Indeed, we find a difficulty in defining servile imitation. No medical practitioner exhibits a new medicine merely to avoid the repetition of what is established as good; no divine starts a new doctrine instead of the old and true one, merely to avoid what is old and true. If a public body has decided upon a large building, and determined to confide to their architect the erection of such a monument, giving him a parallelogram, and only requiring that it have a noble portico at one end, we can conceive no possible reason for any deviation from the form of an antique temple.

If the ground were *not* of such a form, if it were hemmed in by adjoining houses, if the purposes for which it were to be applied necessarily divided the building into several floors, then would the endeavour to make such a building a copy of an antique temple be an absurdity, and the attempt a failure. But even here the servile imitation should not be forgotten. It may be that some covering should protect the entrance, and that for that purpose a portico should be applied to it; where, even in that small portion of the building, can *better* than Greek proportions be applied to the columns, to the entablature, to the intercolumniations? To avoid such servile imitation is again to dash into extravagant heaviness or meagre weakness. To parody an observation of the late Brinsley Sheridan, who is reported, speaking of London, to have said, that "assuredly it was the best place to live in for nine months of the year, and he did not know a better for the other three;" so we say, that nine times out of twelve the Greek proportion is the best, and we don't know a better for the other three.

The judgment to make the true application of this principle, and to bring to the service of modern architecture the established rules of the great masters of the art, may certainly be acquired without an apprenticeship to the craft, nor can such a test ever be applied to its professors. Under it Michael Angelo, the author of the dome of St. Peter's at Rome, Perrault, the designer of the facade of the Louvre at Paris, Sir Christopher Wren himself, and indeed many professors who are at present practising with the greatest success, would not be found upon the roll.

Our business is, however, rather with the unprofessional than the professional, and with the right to judge of architecture which every one assumes, much in the style of the old distich, of which we do not just now recollect either the author or the occasion.

> I do not like thee, Dr. Fell,
> The reason why I cannot tell;
> But this I *do* know very well,
> I do not like thee, Dr. Fell.

This doggrel embodies the whole principle of criticism usually applied by unprofessional persons to architecture; while upon the arts of painting and sculpture no such general observations are made. The picture intended to represent a given subject, either conveys the story or not, either exhibits in natural and characteristic attitudes and expression the sentiments of the scene, or, if it fails therein, the spectator can easily detect the cause of that failure. He remarks that the passion is exaggerated, that the principal action of the scene is not sufficiently prominent, or, descending to minutiæ, he can observe that the proportions of the figures are incorrect, that the heads or the extremities are too large or too small; and he is enabled thus particularly to criticise the work before him, not from any education as applied to the arts of painting or sculpture, but simply from the contemplation of those natural objects that always surround him. The unprofessional critic upon architecture, having no such natural guide, blames or praises without knowing why; and, in the same breath with which he deals out his dislike or his admiration, acknowledges his ignorance of any principle by which his decisions are guided.

But we think that one, and a very essential object of the Architect's Journal, should be to afford some certain data by which not the professors (for they are supposed to have studied it), but men educated to the highest classical and mathematical learning in our universities, should be enabled to discriminate between right and wrong, as concerns the exterior of architecture, its application to its several uses, and the proportions which time has sanctioned. It is surely not enough that they should say "I like it, but I don't know why;" they should see a reason for their likes and their dislikes. By such means incongruities would be avoided, and buildings upon which thousands of the public money have been expended would not remain for ages a mockery and a disgrace to the times in which they were erected. The ordinary course of a series of lectures upon architecture of the present day is the arrangement of dates, a history of the progress of the science, from the hut of the savage to the temple of the gods. But it is surely scarcely worth while to settle with the accuracy of a lawyer, when wood gave way to stone, or thatch to slates, when the pointed arch superseded the round one, or the Greek proportions obtained over the Roman; the point to be settled is, *what is the most beautiful, and in what that beauty consists?*

And now that the profession seems likely to be ever placed under that incubus, competition, which, however, in the case of the houses of Parliament, it in a great measure sought, and which, from the experience of its baneful effects, we most sincerely wish the government had resisted, by asserting their right to the appointment, it will be the more necessary that the public should receive some knowledge of the leading principles of the art. Our objections to the system of competition, which has lately grown up, are—*its frequent injustice to individuals—the utter hopelessness of a competent tribunal* (as regards extensive and complicated buildings)—*its apparent fairness, but masked duplicity.*

In the first instance, by its operation the steady labours and useful attention to the business of public bodies, frequently during a long period, of upholding crazy and antique buildings, is set aside on the plea, that as so large a sum is to be expended, it is right to try, by a general competition, to obtain the best designs. In the next place, as in the case recorded in the last number of this journal of the building at Rugby, is it not lamentable to learn that more than sixty persons should have been induced to give their time to the bare chance of so moderate a remuneration, and submit the decision of the merits of the design to the judgment of a country attorney. Now Mr. Wrat-is-law may be a very good authority for What-is-law, but that very proficiency is the guarantee of his ignorance of another equally difficult science, and he takes or rejects without knowing why or wherefore—an unlearned, if an impartial judge. In the third instance, an opposition (and such will always exist in some quarter) is made to intrusting the new work to their own long employed architect, and in order to carry that opposition into effect the liberal cry of a competition is started. It is impossible to resist it. The party who has probably been engaged for months in endeavouring to please all parties by making his designs square to all opinions, and who thought the business on the eve of commencement, is requested to attend the board. The chairman then informs him that the board are highly satisfied with his zeal and attention to their business, and with the promptitude with which he has forwarded their wishes with regard to the new buildings; they have, however, a *public duty* to perform, and, as a large outlay is to be made, they have thought that the most satisfactory mode would be by public competition. They have little doubt but that the talent he has always shown will on this occasion be successfully exerted. The architect conceals his disappointment under the show of great respect, and retires. The board breaks up. In the lobby he meets the chairman, who takes him into a corner, and says, "My dear fellow, that obstinate fool, Jinks, who has always opposed our building scheme, could only be propitiated by allowing the affair to go to a competition. However, as it has been determined upon, make your designs, and we will take good care that you have it." Now there is a story illustrative of this which we will repeat, because we have heard it from good authority. In a late competition it was *somehow or other known* in the committee that the device of the to-be-favoured one was an anchor. They met, and at the close of the day's sitting, after turning over nearly eighty sets of designs, they found a second anchor. What was to be done? THE Anchor was the object, and that object was to be sought. Accordingly the committee adjourned for a week, got a further clue to their friend's design, and then moored themselves on the right anchor.

In some instances these trials have brought forward talent that it is wonderful the parties were not previously acquainted with. In the case of the Reading drawings, the committee, after seeking by competition the best talent of the whole country, found the designs of a very young man, the son of one of their own directors, superior to all others; and in the Licensed Victuallers' School competition, the design of their own surveyor excelled those of the seventy competitors. This was very satisfactory to the first parties, but it was very unfortunate that the directors could not appreciate such talent without putting so many persons to considerable expense and anxiety, to prove the superior abilities of the party with whom they were so immediately connected.

We therefore condemn general competitions as prejudicial to the quiet working and legitimate rights of the profession, as unsatisfactory in its results, and as (much too frequently) the covering of a concealed fraud.

It will be difficult to persuade the profession generally to acknowledge this opinion, however much the most thinking among them may admit it. We know that the sexagenarin, whose motto is "Dum spiro spero," will not: the experience of forty years has not convinced him that the figure he sees floating above him is the personification of delusion, not of hope. Nor will the bolder professor, whose motto, "Fiat Justitia," would command attention and assumes somewhat of a threat: nor will the youth who takes the motto "Forward." To the two first we have nothing to say, but upon the last we would impress this truth—that he would do himself more good by working out carefully, with all its details, one Roman palace, than by a hundred sets of competition drawings. From their nature he can seek no advice from his seniors, and he is afraid of his equals; for he has always a notion that he has some arrangements that might be filched, and he therefore labours on in the dark from his own inexperienced store. The main plea upon which he is induced thus to exert himself, for which he rises early and goes to bed late, sleeping over his legitimate employers' drawings, that he may be wide awake to his own, is that it is PRACTICE; but it is a practice he had better discontinue, and he will find his account in studies more legitimate, because more congenial to his age. We know no one who will be injured by the abandonment of this bad system, but the picturesque draftsman. Passing from house to house, he daily performs as great a miracle as Joshua, for he makes the sun to shine from every quarter of the heavens, and illuminates the east and the west, the north and the south aspect of his building with the same brilliant light. How many porticos are spread along the eastern and northern fronts of this great city, adding gloom to natural darkness, which, we will venture to assert, when submitted on paper to the persons who were to decide upon their adoption, were glowing with sunshine. Had the parties recollected that, in the eastern front, no such effect could exist after ten o'clock in the day, and that, in the northern, it would at no time be so illuminated, would they not have hesitated so mischievously to expend their funds in perpetuating gloom without shelter, and heaviness without relief.

But seeing the utter impossibility of obtaining a sufficiently informed tribunal, through any but professional assistance, and feeling the extreme difficulty of prevailing upon parties to surrender their judgments in such matters, we fear it can neither be checked nor directed by any thing but a better education and enlightenment to the principles and philosophy of the art. The ignorant cry, "Am I not to be pleased with what I pay for?" should be deprecated and denied; for no one has a right to inflict on posterity his whims, caprices, or tastes, in opposition to the approved opinions of professional education. If he will wear the cap and bells, he is at full liberty to do so in his own person, but he has no right to perpetuate them in marble or stone upon his descendants.

If it be, however, advisable to sanction a so generally suspicious proceeding at all, we should say that the system of nomination as adopted by the committee of the Reform Club was the best. The remuneration to the unsuccessful parties was very inadequate, and we believe was not claimed, but it should have been more equal to their trouble, and the drawings should in that case have become the property of the club, with liberty to engraft on the most approved design any parts of them the committee might think advisable.

Herein is a positive and considerable expense, but there is in return positive and considerable advantage—namely, the satisfaction of knowing that although you have not swept all England, from John-o'-Groat's to the Land's End, for ideas, you have obtained the opinion of the most experienced, and selected from the most eminent of the profession. Our remarks do not, however, bear upon the competitions for the Nelson and Wellington Memorials. We are fully convinced that a committe of noblemen and gentlemen are as equal to determine whether they shall be embodied by a column, an obelisk, a group, or single figure, as any body of artists can be; but we deny the competency of such parties to understand a set of complicated drawings for an extensive building, and the relative bearing of the plans, sections, and elevations, upon each other. They will be guided to their decision by that most imperfect organ of our senses—the eye, and the result will often be an almost utter abandonment of the plan itself, from some impossibility of construction, and of the most leading features of the design that captivated their understanding, from its utter uselessness. And this is one of the most serious objections to which general competition is subject, both as regards the architect and his employers. Careless of pleasing himself, his object is to hit the taste or mystify the judgment of a committee; instead of graceful movements, he substitutes pirouettes that shall astonish, and sacrificing his own studies and feelings to the necessity imposed upon him, shelters himself, as he places his enchantments upon paper, behind the authority of Dryden—

> "He's bound to please, not to write well, and knows
> There is a mode in plays, as well as clothes;"

upon which lines the poet's annotator, Landsdowne, has this remark: "Who writes to live, must unavoidably comply with their taste by whose approbation they subsist; some generous prince or prime minister, like Richelieu, can only find a remedy."

We may probably wait a long time for the happy advent, but when the reign of good sense shall arrive, the architect will be allowed to

embody his own designs, and be no more controlled by his employer, than the physician in the composition of his prescription, or the lawyer in the phraseology or terms of his settlements.

"The better please, the worse displease, I aske no more."

J. H.

REMARKS ON AN ANTI-PYRETIC COMPOUND,

FOR RENDERING TIMBER FOR HOUSES, SHIPS, AS WELL AS FURNITURE, NON-COMBUSTIBLE, OR NOT LIABLE TO TAKE FIRE; AND ALSO FOR PREVENTING THE DRY-ROT AND DECAY.

By John Hancock, M.D.

The following remarks have originated from experiments made long since; but, owing to other engagements, they have hitherto lain neglected.

Considering the immense destruction of property annually caused by fires throughout the British Empire, and their ruinous consequences, especially in so dense a population as this metropolis; considering, too, the immense amount of property and of lives embarked in British shipping, and their liability to those horrible disasters which not unfrequently occur from the consuming element at sea, where no means of escape are afforded to the miserable sufferers, I am induced to hope that the following propositions, founded on many experiments, will, at an early period, meet that attention of the British Government, which the importance of the subject so justly demands.

The object of these experiments, to which I have devoted much time and attention, was to find out a cheap and easy method of rendering wood and other materials incombustible, or not subject to take fire. To this end a great number of different substances were, with varied success, submitted to experimental examination; and after numerous trials, made with all possible care, I have discovered a chemical compound, possessing all the properties so long sought for—seasoned wood, saturated therewith and dried, being found to resist the action of fire far better than greenwood, or that which had been recently and long soaked in water. In fact, it is thus rendered incapable of feeding flame, or of propagating combustion, where a fire has commenced.

The most prominent recommendation of this method is, that it affords not only *security against fire*, but likewise *preserves timber from decay*, or what is called the dry-rot—a decomposition which is supposed chiefly to result from the growth of vegetable fungi. The same process, it is believed, will be found to prevent the depredation of worms in timber; but for this object no adequate trials have been made.

Corrosive sublimate has long since been proposed, and is now employed, as a preservative against the dry rot. It is indeed a powerful agent against the desomposition of vegetable matter. It should not be forgotten, however, that corrosive sublimate is one of the most active of the mineral poisons—not surpassed even by arsenic; and, in a smaller dose, it has been said, will destroy life. We are told, indeed, that Dr. Faraday has asserted that corrosive sublimate emitted no hurtful effluvia. This asseration may unintentionally delude the public, by using a name so justly venerated. It is well known that corrosive sublimate is not a *volatile* poison, and no one could expect its effects to be exerted through any exhalation; but in any dwelling-house, where the timbers and boards have been soaked in its solution, it must be highly dangerous, especially when there happens to be any moisture, percolation, or dripping therefrom, which might be frequently liable to fall into food or drink; and a ship so prepared (with the sublimate) would be still more liable to such accidents, being often exposed to extreme moisture. Besides all this, the expense of corrosive sublimate must, for ordinary purposes, be a material objection to its general use. It seems extraordinary, indeed, that such an extensive use of this poison should be tolerated, when we consider what an outcry and alarm were lately excited by the discovery that a few grains of arsenic were employed in the manufacture of candles.

It appeared desirable, therefore, that a more eligible substance should be sought for; and one that should *preserve timber* not only *from the rot*, but also *from accidents by fire*. This double desideratum, it is presumed, has now been realized.

The expense of materials for the preservation of timber in the manner proposed, to guard against fire and against the dry-rot, is very trifling, as will ben subsequently proved.

It is important to observe that, besides the preparation of the materials *intended for the construction* of ships and buildings, the same preservative may likewise be applied *to those already constructed*, and afford them nearly equal security against accidents by fire. This could readily be effected by throwing the prepared liquid over the floors; while joists, skirtings, casements, and other parts liable to take fire might be prepared by saturating them by the use of sponges dipped in the liquid. It is a fact well known to firemen, that nine times in ten it is either the floor, or the casements adjacent to the chimneys, which first take fire; it is, therefore, of great importance that the wood-work so exposed be prepared with double care, or more effectively imbued with the anti-combustible compound.

It would be absurd to pretend that wood can be rendered incapable of being consumed, when it is a fact well known that iron and other metals are combustible by strong heat. All that is meant here is, that it is rendered, by the present process, uninflammable, and capable in a great degree of resisting the action of fire; so that, where a fire has commenced, it cannot advance, or be propagated on materials subjected to the preparation; and thus all kinds of wood may be made to resist the action of fire, excepting that which greatly abounds with resin, and which occurs in the American pitch pine, though rarely to that degree that it will not imbibe any whatsoever.

Such articles as tapestry, bed-curtains, &c., are, as is well known, very liable to take fire; these may be prepared with the anti-pyretic solution diluted, and will be preserved from the depredation of moths and insects, which are so destructive to furs, to carpetting, and divers kinds of furniture.

The same preparation is not only effectual as a preventive, but also most powerful in *extinguishing* fire. One charge of the engine with this solution will effect as much perhaps as eight or ten with common water; and besides, when thus extinguished, the fire will not rekindle. This is an important point gained, when we consider the devastations which too often occur after the fire is thought to be extinguished. Parkes, in his Chemistry, makes the remark that water, in many cases, accelerates combustion; and we cannot wonder at this, upon reflecting that water is composed of hydrogen and oxygen, the most combustible substances in nature, and producing the most intense heat. Water, by the agency of heat, is decomposed, and thus becomes the fomites or pabulum to flame. Greenwood, it is certain, makes a stronger fire than dry, and coals are sprinkled with water to increase the heat of the forge; and on this principle is founded the recent invention of Mr. Rutty, in the combustion of water with resins, oils, &c. The London firemen are partly acquainted with this fact, and assert that when the fire rekindles it burns with great fury, and is the more difficult to conquer. This was exemplified both in the conflagration of the Houses of Parliament and of the Royal Exchange.

Those who may still consider corrosive sublimate as the most efficient preventive of dry-rot, may add this to the compound. The salts therein dissolved, so far from being incompatible with the sublimate, render the whole more soluble; and the timber thus prepared may perhaps be found still more capable of resisting the decomposition which occurs from the ordinary action of its own elements. Thus we have a preparation even more efficient against the dry-rot than the simple sublimate solution, and at the same time a safeguard against the destructive effects of fire; and it may well be thought surprising that more attention should not have been given to this most important desideratum.

If a further security for laths, posts, beams, &c., be thought desirable, we may give them a coat of stucco or cement, which might afford an additional security against fire. The composition recently tried at the White Conduit House, and at Kennington, is of this sort, which, however, is not more effectual against fire than the ordinary mortar formed with lime, terrace, &c.; and it is not applicable to panels, partition boards and sashes, nor to the pieces about the fire-place, nor upon the floor-boards—parts most exposed and liable to take fire. Every one is aware that mortars and terro cement, like other earthy matters, are non conductors of heat; and, applied in a thick coat, may be used with advantage against fire, in the hidden and coarse wood-work of houses. This method was invented by the late Earl Stanhope (then Lord Mahon), and was published by him in the Philosophical Transactions for 1778.*

It is a well known fact that wood becomes still more inflammable by the turpentine and oil used in paints. An incombustible paint might be also formed. If, however, the wood be duly prepared, it will remain untouched, even should the paint be consumed upon it. Welbeck Street, London, September, 1830.

SUBSTITUTE FOR GRINDSTONES.

Sir,—From the frequent deplorable accidents which occur in manufactories where large grindstones are in use, especially where they are required to revolve with great rapidity, I venture earnestly to recommend to the attention of all those who employ them, the substitution of the grinding vehicle constantly employed in Hindoostan, in the use of which, of whatever size it may be required, no dangerous accident can possibly occur.

This is merely a composition made of shell lac, rendered plastic by heat, with powdered corundum of different degrees of fineness. Of course emery or any other grinding matter may be applied suitable to the purpose.

There are many advantages attending the use of the Indian grindstone, which, besides those which humanity will dictate, are worthy of attention.

If a grinding surface parallel to the axis of rotation is required, a drum of sheet iron, coated with the composition of shell lac and emery, to the depth of half an inch, presents a durable form of grinding apuratus, free from every possibility of accident. Ground glass, or silex, or even the powdered remains of broken and worn out grindstones, may be used instead of emery, for coarse purposes.

If a flat grinding surface, perpendicuar to the axis of rotation, be required, a disk of sheet or cast iron is at once a durable frame for the same.

If curved grinding surfaces are required, I need not mention how easily the frames can be formed of the necessary curves, and the utmost accuracy of turning may be applied to render the grinding surface of emery and lac perfectly true.

The heat of a red hot iron, applied near the surface, sufficiently softens the composition to enable the workmen to renew the cutting surface of the emery, as often as required, and it must be recollected that water has no action whatever upon it.

While upon this subject, I may mention the facility and economy with which polishing brushes of every variety of size and shape may be made, by coating the frames of drums, &c., with shell lac to the depth of half an inch, and then inserting the bristles for the polishing surface in holes made in the cement with fine heated wires.

I sincerely hope that some eminent engineers will introduce this description of grinding apparatus into their workshops, when I have no doubt their advantages will be immediately perceived.

Yours, &c., SAMUEL PARLBY.

* This invention was put to the severest test by that ingenious and talented nobleman, in the following manner:—A fire was kindled with faggots close to the prepared building, and a room filled with combustible materials was fired; the flames rose to the height of more than 80 feet, all the glass in the windows of the room was melted, yet the building remained unhurt.

WHITE'S PATENT TENSION RAILWAY.

FIG. 1.

Perspective view of Support Pile, Block, Rail, Wedges, &c.

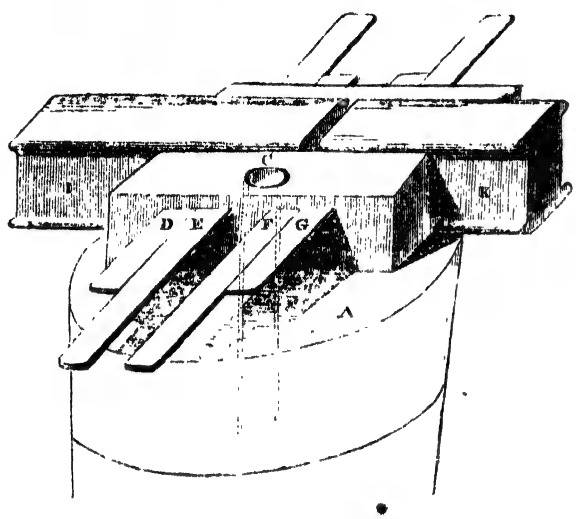

FIG. 3.

Plan of Support Pile, Block, Rail, Wedges, &c.

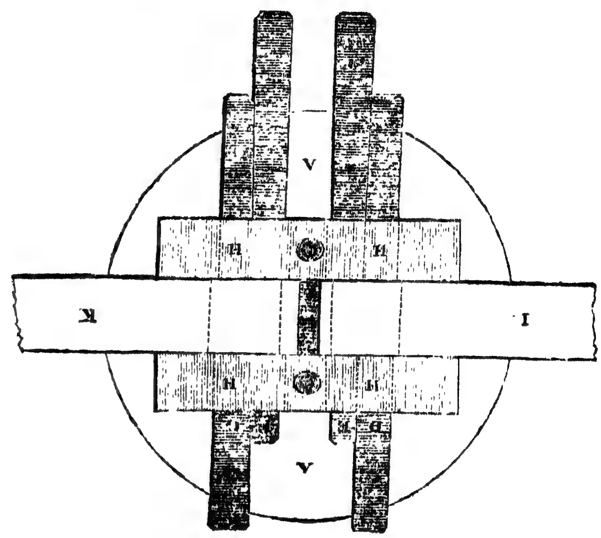

FIG. 2.

Longitudinal Section of Support Pile, Block, Rail, Wedges, &c.

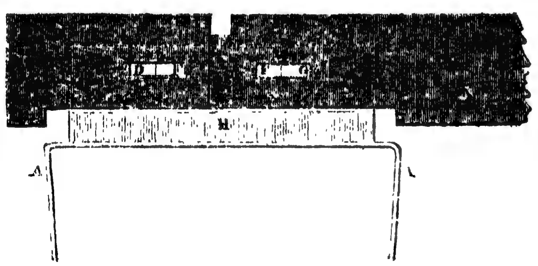

FIG. 4.

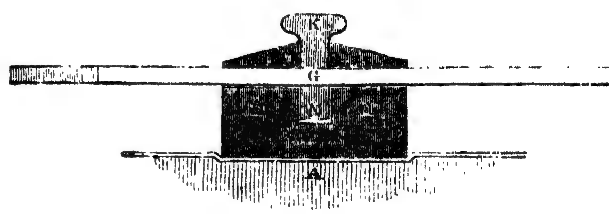
Section of Rail, Block, Wedge, &c.



SPECIFICATION.

The nature of the invention consists in adding strength to such metal rails and bars as may be used for railways, and also to such timber beams, supporters, and bearers, as may be used in the construction of bridges and viaducts, by giving tenseness to the same by means of keys or lateral wedges as hereinafter described.

Figure I. represents the invention as applied to railways, A. being what is called a resistance pile, with one of the patentee's blocks or chairs, with its wedges for giving tenseness to the bars, which form the rails fixed upon it; H. is a block of iron sunk into the top of the pile A., and there spiked down by spikes as at the parts marked C.; through this block are cut horizontal mortices to receive the lateral wedges or keys, D. E. F. G., while corresponding mortices are cut in the rails I. K., to allow the wedges to pass through, these resistance piles may be at any convenient distance from each other, say about one-sixteenth of a mile, and between them, at intervals of about fifteen feet, common piles should be driven to receive similar blocks of a similar size, and fastened down by spikes passing through holes sufficiently larger than the spikes to admit of the play consequent upon expansion and contraction; I. K. represent portions of railway rails, their ends being slid into groves cast to receive them in the block H till the mortices in the block and those in the rails sufficiently correspond to admit of the introduction of the small ends of the wedges, but leaving a sufficient space between the two ends of the rails to admit of their being extended by tension, or of their expanding with increase of temperature. The rails being so placed, the wedges or keys D. E. F. G. are inserted and driven up, and if the resistance piles are sufficiently braced and strutted not to yield by the driving of the wedges, any required tension may be given to the rails. Fig. 1 is a perspective elevation of one of the support piles; fig. 2 is a longitudinal section; fig. 3 is a plan and fig. 4 is a transverse section. It is evident from the foregoing that, if two fixed points be obtained at each end of any metal bar used as a beam or support, or as a stretcher, or a bearer, in the construction of any bridge or viaduct, tension may be given to it by means of blocks and lateral wedges, similar to those hereinbefore described, and by means of that tension additional strength imparted to the said bar, and, likewise, to any timber beam, support, or bearer, so used. The Patentee claims as his invention the application of tension in manner aforesaid, to all such metal rails and bars, and also to all such timber beams, supports, or bearers, used in the construction of railways, bridges, and viaducts, as are capable from their nature and situation of having such tension as aforesaid applied thereto, whereby he imparts great additional strength or power of resistance to the said metal rails and bars, and to the said timber beams supports, or bearers.

STEAM BOILER ALARUM.

COMMUNICATED BY MR. HENRY DYOTT GARDNER.

Fig. 1.—Interior of Boiler; side view of Apparatus.

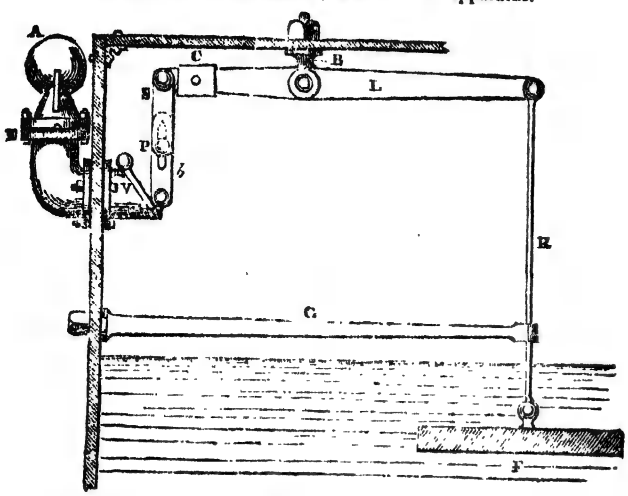


Fig. 2.—Plan of Apparatus.

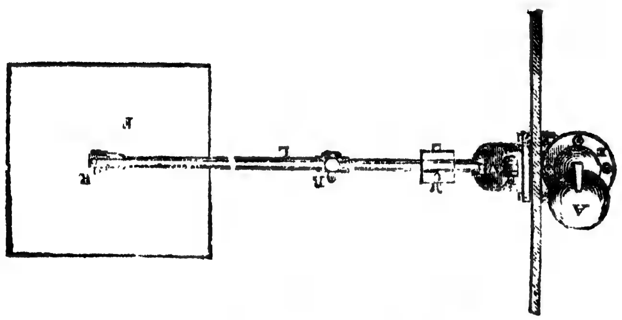

Fig. 3.—Front view of Alarum or Whistle.

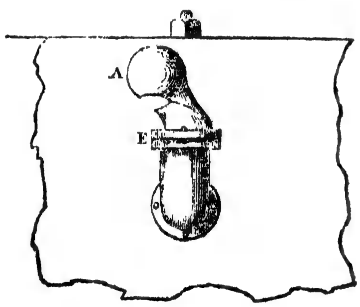

REFERENCE TO FIGURES.

F float, which is connected to the lever by the rod R; S, slings; b, link; P, pin which connects the slings together, passing through the link b; V, valve; A, alarum; G, guide to prevent the float rod oscillating; B, fulcrum to support the lever, and is fastened to the upper part of boiler by means of the nut on the outside.

At E a small valve is introduced to prevent the air entering the boilers, when being pumped up by what is generally called the vacuum pump.

The frequent accidents which have lately occurred to the boilers of marine engines, in consequence of the water becoming too low, whereby the plates are over heated, induced me, within the last few weeks, to seek for a method by which such accidents may be avoided, by the Engineer in charge having timely notice when the water in the boiler descends below a certain level. Annexed is a drawing, showing an apparatus I propose for preventing such accidents; it consists of a float F., attached by a rod R. to a lever L., about two feet long; the other end is connected to a valve V., of about two inches in diameter, and attached to a pipe E. in front of the boiler, with an alarum or whistle A. at the end. I propose the float F. to be a piece of flagstone, which must displace as much water as is necessary to overcome the resistance of the steam acting upon the valve V., &c.; the dimensions may be about thirteen inches square, and two inches thick; counterpoised (when suspended in the water) by a weight C. upon the opposite end of the lever L., the preponderance being given a little in favour of the short end, which is connected to the valve V. by means of a link B., and slings S., with a pin P., which passes through the link, and allowed to play freely; this mode of connection permits the float to oscillate, should it have a tendency to do so, without disturbing the valve. When the water sinks below a certain level, that is, under the upper edge of the float, its gravity will cause it to descend, thereby depressing the long end of the lever, the short end being proportionally elevated until the pin in the slings comes in contact with the upper part of the link; at this juncture, upon a farther descent of the float taking place, the valve is opened, and the consequence will be an escape of steam, which lifts the small valve at E., and rushes through the pipe, and out at the orifice in the alarum, and whistles, thereby giving due notice to the engineer in case of danger. To prevent corrosion, the apparatus had better be made of metal, and the pins and joints allowed to work free.

HENRY DYOTT GARDNER.

Near the Howick, Woolwich.

[A steam whistle has been many years in use for the purpose of an indicator, to denote the descent of the water in steam boilers below the proper level; the method is to pass a piece of gas or small pipe through the boiler, one end to be as high as the feed head, and the other to extend within the boiler, as low as the water may be allowed to descend with safety. When the water passes this point, the steam rushes through the pipe and sounds the whistle. In Government steam boats a similar pipe is carried up the side of the funnel, until the altitude of water in it is sufficient to counterbalance the pressure of the steam; it then returns in the shape of a syphon to the stoke-hole; if the water gets below its proper level, the steam rushes through the pipe, and acts in a similar manner to that we have just described. Both these methods are only applicable to low pressure boilers, and are liable to serious accidents on board of steam vessels, particularly war steamers; for if a cannon shot, or any other disaster, were to carry away the pipe, the consequence would be, that the water, to a certain depth, would be blown out of the boiler, during which time no person could approach to check it.

We have lately seen another contrivance, adopted by Messrs. Maudslay and Field, for high pressure boilers, which we believe acts in the following manner: we only saw it for a few minutes; probably some part of the description may not be exactly correct in detail:—A tube is fixed perpendicularly to the top of the boiler, part within and part without; a small pipe is made to fit very accurately the inside of this tube, through which it passes; the pipe has two apertures, and is made longer than the external tube; one of the apertures is near the top, and the other about a third from the bottom of the pipe; to the end is suspended a float, similar to that shown in the above drawing; the top or upper part is attached to a chain, which passes over a pulley, and suspends a balance weight, which is so adjusted as to allow the float to be suspended at its proper level, and the lower aperture of the pipe to be enclosed within the tube, consequently no steam can pass through the pipe; but if the water in the boiler sinks beyond its proper level, then the float descends and pulls down the pipe, until the lower aperture is below the tube, when the steam immediately rushes through the pipe and out at the upper aperture, and produces a noise similar to a whistle. This is a very simple and excellent contrivance for steam engines on land, but for marine engines it is liable to the same objection as to the last method described, in consequence of the apparatus being above the boiler. The contrivance of our correspondent, Mr. Gardner, is applicable for both high and low pressure boilers; and, as nearly the whole of the apparatus is fixed within the boiler, and all below the deck of a steam vessel, it is not liable to those accidents we have enumerated. We consider the simple introduction of a steam whistle ought to be adopted for all steam engines; the cost is comparatively trifling. —Ed.]

TASTE AND THE FINE ARTS AT OXFORD.

It is certainly one of the great features of the present age, that it has not only created new establishments, but that it has given an unusual impulse to the old ones, and in many cases roused them from their slumbers. No where perhaps has this spirit produced more effect than in our universities, and particularly at Oxford. More perhaps has been expended on repairs in the last ten years, than probably in the whole century before, and the corporations feeling themselves under the public eye, have been induced to devote those revenues to their original destinations, which in many cases had been diverted to personal objects. It is a subject of congratulation, too, that in carrying out the recent improvements, a proper attention has been shown to

preserve and restore the original styles of the buildings, and maintain their purity. Among the latest of these restorations are those effected in the Cathedral of Christ Church, where several of the details have been reproduced, which had been destroyed or concealed by the barbarism of former architects. With the progress of the works now going on in our cathedrals, we shall in a few years stand without rivals in this splendid branch of Gothic architecture, and we trust that the purification of the style of the edifices, will be the signal for a revival of the splendour of those admirable schools of art, from which our fathers produced so many triumphant works.

In the chapel of Magdalen College is a curious discrepancy. As is well known, the interior is in the pointed style, but on the steps of the altar have been recently erected two magnificent metal candelabra. Those are as purely Greek, and as dissimilar from the style of the surrounding objects as possible; but they are still farther distinguished by another feature: the glasses being considered of an inelegant shape, in the attempt to rectify this fault another anomaly was created, a Gothic quatrefoil rim being placed round the glasses.

It is worthy of remark, that the collections of Oxford contain perhaps a greater proportion of unnamed pictures than in any other gallery, and it is a practice which is well worthy of imitation, and particularly in the Trafalgar Square exhibition. Nothing can be more mischievous to the public taste than to give suppositious names to works, which can generally do quite as well without any name at all. It is doubtless from this system of imposition that a bad standard of criticism has been created in England, and gulled our connoisseurs into the purchase of more trash, than is to be found in all the other nations of Europe. The National Gallery, with its Andrea del-Sartos will vouch for this; and, indeed, in most details of administration it is far behind the collection in Christ Church College, in which latter the works are at least arranged according to masters, and all the early artists are brought together in a manner that enables the eye at a few glances to view the whole progress of the art.

But while we are disposed to give great credit for the general disposition of the collections, we feel it our duty particularly to reprobate the manner in which the Pomfret gallery is conducted. This, most of our readers are aware, is composed of a number of antique statues, and fragments collected by the Earl of Pomfret, and by him presented to the university. Will it be believed, that in the richest university in the world, that this collection is worse arranged than any wax-work in Bartholomew fair? and yet such is the disgraceful fact. The room, called the School of Metaphysics, or some such name, has very much the appearance of a barn; and the collection, which is under the superintendence of the Clerk of the Schools, is exhibited by an old ignoramus, not fit for a two-penny showman. After paying a shilling to this Mercury, the visitor finds himself in a large dirty hall, with a badly written manuscript catalogue lying on a table. The statues and fragments generally rest upon remains of old boards and shutters, and the numbers are scratched upon them with a bit of charcoal. In fact, there is no collection in Europe, and we have seen many, which at all approaches in inattention and neglect to this beggarly display, and it is the more inexcusable when a sum of ten pounds and a common painter would at any rate suffice to put it in a more respectable condition. We should be happy to see the attention of the heads of the university called to this flagrant disgrace, for we feel assured that men who display so much reverence for even a letter in a Greek manuscript, would not willingly suffer such disrespect to these monuments of ancient art.

ANALYSIS OF STONE.

We last month gave a translation from the German of the experiments on stone at Munich, and we are happy to find its utility confirmed by the course proposed to be adopted with regard to the stone for the new houses of Parliament. Mr. Barry has been on a tour with Mr. De la Beche, the geologist, to examine the stone in different quarries, and having brought back many specimens, they are now about to subject them to the test of chemical analysis The importance of ascertaining the durability of the means of construction is apparent to every one, and it would be well had such a practice been adopted at an earlier period. Without alluding to St. Paul's, the recent repairs of the bridges urge the necessity of this, and enforce the economy of using a better stone in the first instance, rather than by using cheaper, or more available materials, incuring future expenses for repairs. The shelly buildings at Oxford, which are now being faced with other material, do not serve as an example to prevent the use of similar bad stone in other buildings there. From a want of attention to this point, tomb-stones, intended for perpetual memorials of mortality, in many damp parts of the country fall into dust almost as soon as the being they are intended to commemorate.

ON THE LAYING OUT A LINE OF RAILWAY PREVIOUS TO EXECUTION.

Sir,—Thinking it might be of service to some of your readers, I send you the following hasty observations on the above subject; if acceptable, I may at some future time send you something more worthy of your pages.

The first step in carrying a line of railway into execution, is to have the centre line accurately set out; to do which, with any pretensions to accuracy, a theodolite must be used in every part of the operation. Indeed, it is utterly impossible that a line can be set out perfectly straight for ever so short a distance without it.

It is not my intention at present to go into the method of setting out the centre line any further than to recommend that curves be put in, in the manner explained by Mr. Henry, in the Railway Magazine, and also in my treatise on "Engineering Field Work." It is the only way that I am aware of in which subdivision of labour may be applied; and I can state from experience, that it is the most convenient. My object at present in addressing you is to point out the very erroneous manner in which the various widths required for a railway are often put in. As I have mentioned above, the centre line is (or should be) first set out. Stakes being driven at equal distances of one or more chains apart, the section is then taken on this centre line, without regard to the inclination of the ground on either side. Sometimes, indeed, cross sections are drawn on the principal section; but this is quite useless, so far as the widths required for any given cutting or embankment; for in the first place, without these cross sections are taken at the exact points, or in fact from off the stakes on which the principal section ought to be taken, they are quite useless, any further than to give a general idea of the inclination of the ground. I have observed on many lines of railway, where the centre line has been on sideling ground, that square, or equal widths from the centre line have been marked not only on the plan, but on the ground. What could be more erroneous? Take for instance an embankment of 20 feet, with slope 2 to 1, the width required on level ground would be double that on each side the centre line; plus half the width of roadway and ditching, but the latter being a constant quantity, must be omitted in the calculations. Suppose the ground to be sideling, and at the estimated distance for level ground from the centre line, the fall should be 10 feet, the extra width required would be that quantity multiplied by the slope, which would be 20 feet; but there would probably be a fall of say 4 feet in this additional width, which again multiplied by the slope would give a further quantity of 8 feet, to be added to the above, and in this 8 feet there being probably a still further fall of 18 inches, would make 3 feet additional; it will thus be seen that in the above case an additional width of 31 feet on one side of the road would be required, more than was calculated on. This is no trifling matter, as it would be found, when the work was carried into execution (if not before), additional land would have to be purchased at most likely an enormous price, or perhaps property would be required that was not in the first place contemplated, and which might not be to be had at any price. Retaining walls, or quickening the slopes, might perhaps get over the difficulty, but the evils are too apparent to require further comment. On the other side of the embankment, if the ground continued at the same rate of inclination, a great part of the estimated width would not be wanted; the actual quantity to be deducted from that estimated for level ground, from the centre line, would be twice the difference of level, or 20 feet minus the fall in that distance multiplied by the slope, which taking the fall as before at 4 feet would be 20 feet—8 feet=12 feet; to which is to be added twice the difference of level of this last quantity, which, as we took it before, is 3 feet, the total quantity to be deducted would then stand thus: 20 feet+3 feet—8 feet=15 feet. It should be carefully borne in mind, that in cutting the preceding operation is reversed. By the above method it will be perceived that the whole of the widths of any line of railway must be put in with the spirit level, which may at first appear tedious and complex, but in reality it is not so, and with a little practice can be very quickly done; and, moreover, the only method (that I am acquainted with) by which it can be done with any pretensions to accuracy.

Charlotte-street, Bloomsbury. PETER BRUFF.

SUGGESTION FOR OBTAINING PROFESSIONAL INFORMATION ECONOMICALLY.

Sir,—Allow me to suggest, through the medium of your valuable Journal, to the young members of the profession of Civil Engineer and Architect, a manner of obtaining such printed information at moderate prices, as the present system of book-making and luxurious engraving places beyond the reach of their not too well filled pockets. It has become a sad truth that a young man who, wishing to purchase a professional library, should make choice of the works published by the men who are considered the heads of the profession, will, when he has with difficulty spared five or six guineas to buy one work, find it to contain but a small portion of what may be useful to him. On the other hand, he will probably find many beautifully (expensively) executed drawings, different from one another merely in consequence of some slight, and unimportant variety of ornament or dimensions, in no degree affecting the principle; or many plates in succession occupied, or partly occupied, by copperplate engravings that might easily have been condensed into a page of type or woodcut, or, at any rate, into one copperplate outline instead of a dozen finished (and five shilling) engravings. Should another hard-earned and hardly-spared five guineas be laid out on another author's production, there will be found the same subject, and the same drawings (or, otherwise, similar drawings) of the very same things, while a large portion of the text will probably consist of copies of Acts of Parliament, compliments to directors of companies, or examinations of evidence in committees, given (as the author generally tells you, with consummate *nonchalance*) in the very words.—Thus:* "Mr. S. was requested to state to the committee the result of his observations, and the following questions where put to him:"—Q. Do you think that, in case of the velocity being infinitely increased, the continuous bearings would give way; and if not, what is your opinion?—A. I do not think that, in case of the velocity being increased to an extreme degree, that the continuous bearings would give way; but my own opinion is, that in such circumstances the said bearings would not give way. Or Mr. B. makes the following observations:—"The strength of the rails," he observes, "may &c." Now if this verbiage were got rid of, not only would the subject be more intelligible and more attractive to readers, but ponderous folios might be exchanged for compact quartos,

* I would not copy from one work in preference to another. Your readers will remember many examples of the kind I have represented (hardly in caricature?).

and by reducing the size of the type,* and using thinner paper to pocket duodecimos—fit and agreeable companions for the field. I would propose the association of the younger members of the profession: that a library of reference for one copy only of the best works be bought. Let a committee of their own members be selected by ballot, who should select from these works the most useful treatises and drawings, and let these be condensed (an operation which a little practice would render easy to any tolerably good clerk) and printed in a neat and economical manner. I would also observe, that, although there is abundance (numerical, at least) of elementary works, there is still great want of books on the details of practice. Those who have to do with details, are generally too hard-worked at that practice to have time or inclination to write about it, and they imagine that what is familiar to them must be so to others. This I take to be the reason that a catalogue of books on engineering or architecture may be divided, without exception, into theoretical elementary works, and histories of works of such magnitude as occur but rarely, and fall to the lot of only a few. We want also an account of the numerous instances in which works have failed, with the best assignable causes of such failures. If works fail from the want of skill of those who direct them, the public ought to know it; if from other causes, the reputation of the architect or engineer will be bettered by their being made generally known. Navigators place buoys to mark shoals and rocks that should be avoided, and steer boldly into the open sea. Were buoys to be placed on the dangers of science, we might also steer out into the open; and though new shoals and rocks would cause new shipwrecks, new discoveries would be made, and the interests of science better served, than in keeping, as at present, to an inshore navigation.

Yours, &c., B.

ARCHITECTURAL SOCIETY.

SIR,—In your last number there appeared a letter, bearing the signature of "T. Square," which I think calls for a few observations, and to which, in justice to those gentlemen on whom it seeks to throw a slur, you will, I am confident, give a place in your next number.

It would be an invidious and difficult task to decide who formed the "chief members" of the Architectural Society; those who have seceded or those who remain. It would first be necessary to determine whether talent, or zeal, or liberality, or whether the circumstance of being amongst its earliest adherents, constitute the title to chieftancy. But, so far from its being the fact, that the Architectural Society is still composed of those gentlemen who (as it would be inferred exclusively) "ever took its interests into their consideration, and supported it by their exertions, abilities, and funds," I will venture to assert that the list of those members who considered that a junction of the two societies would be advantageous to the profession generally, and who have seceded from that to which they originally belonged, because they believe the Institute of British Architects better qualified to carry out the objects they have in view, and because they felt regret at what appeared to them prejudice and unreasonableness on the part of those who were dissatisfied with the terms proposed, contains the names of gentlemen whose unremitting exertions, whose abilities and generosity, will fully bear comparison with any who may remain; and whose zeal and pride in the Architectural Society was unquestioned, until her numbers had decreased, and apathy had usurped the place of that energy and spirit, which was her strong ground.

Your correspondent lays great stress on the laudable exertions of those gentlemen who "established that institution," and to several of whom he is known, his acquaintance must be somewhat limited if he fancies they all remain, or were subsequently its most useful members; of 15 of the earliest members, eight have seceded, two are abroad, and five remain, of whom one is a strong advocate for the union of the two societies, and one rarely attends the meetings.

It is unnecessary to recapitulate the arguments which were used in favour of uniting the two societies; they have failed to convince the prejudiced feelings of those to whom they were addressed; the public have, however, to learn that ours is the profession of all others which possesses sufficient power and influence, and is strong enough in the number of its followers to admit of two distinct societies being advantageously carried on.

You announce the probable accession to the Architectural Society of Messrs. Tite, Savage, Ianson, and Smith, and to the respectability of these gentlemen I gladly bear testimony; but, Sir, I have heard so often of their intended adherence, without seeing it confirmed, that like the person in the fable, I have at last learnt to mistrust the cry of "Wolf." I do, however, regret that their zeal in the advancement and high-standing of their profession had not induced them to give the benefit of their co-operation to the Architectural Society, at a moment when her members were zealous and succeeding in their efforts, and when their advice and assistance would have been invaluable, rather than to withhold it until disagreement and separation had nearly broken up the society, and when their adherence may admit of other motives being put upon it, than the pure and laudable ones, which at an earlier period would have been an undoubted consequence.

I could say more on the "modesty of your correspondent's remarks about a new era in architecture," who, by a process of reasoning only known to himself, confines the "foundation" of this wonderful superstructure to Lincoln's Inn Fields; but I have already trespassed too much on your attention, and will merely add a corrected list of those who have resigned as members of the Architectural Society.

I am, Sir, your very obedient Servant,

STRAIGHT EDGE.

T. H. Wyatt, Vice-President and Trustee; T. L. Walker, Hon. Treasurer, J. B. Watson, late Trustee; George Moore, O. Jones, H. Duesbury, D. Brandon, and B. Ferrey, Members of the Committee; W. Wright, H. Flower, J. Johnson, E. Woodthorpe, T. T. Bury, C. Lee, C. Parish, and C. J. Peirce, Members.

IVISON'S PATENT APPARATUS FOR ECONOMY OF FUEL, &c.

SIR,—In your last number of the "Engineer's and Architect's Journal," I perceive a succinct account of Mr. Ivison's arrangement for throwing steam on the fuel, in order to effect a perfect combustion of smoke. When the account was published in the *Times* and other journals, I concluded that the patent involved some peculiar arrangement for the above purpose; but the extract contained in the Journal, evidently furnished by the friends of Mr. I., disabuses me of the erroneous conclusion I had formed, since therefrom it clearly appears that Mr. Ivison lays claim to the *principle*, and not to the peculiar arrangement: indeed, the plan of the bridges, for the precipitation of the ashes and refuse of the fuel, is a mere hint; it is the combustion of the vapour is the grand invention—no more, no less. Now, if this really be the case, I am afraid Mr. Ivison and his friends have expended time, labour, and expense, to little purpose. For my own part, I would as soon have taken out a patent for throwing salt upon the fire as a consumer of smoke, as for throwing steam—since I believe both one and the other have been in use from time immemorial. It is far from my wish to deprecate a useful invention: I merely wish to ascertain the simple fact, whether, when a person has, in the common routine of his employment, been in the habit of carrying into practice a certain principle, and that for a number of years—whether, I repeat, any other individual can, by slightly modifying the arrangement—for such I shall presently show is all Mr. Ivison can lay claim to—take out a patent thereupon, and henceforth compel the public at large to pay 1*l.* *per horse power* per annum (I quote the words of Mr. William Watson, of Main Point Foundry, Edinburgh). During my term of apprenticeship, served in the south of England with a manufacturing chemist, it was our invariable custom, when we wished to procure strong red heat in our furnaces, to throw water on the heated ashes in the pit, in order that the vapour thereof, impelled by the draught, should pass upwards through the grate and be there consumed by the red-hot coal. Observation had taught those who instructed me that water, either in the form of a vapour or a liquid state, would materially assist combustion; and not only the blacksmith who sprinkles his fire, but if I remember right, several others, in their experiments, have proved that water, particularly in the diffused state of vapour, materially assists in procuring a bright clear fire, or in consuming its own smoke.—Vide "Arnot's Elements," Physics.

So well did this principle of impelling vapour through or against the burning fuel, to effect a more perfect combustion, appear to be understood, that our ashpits were constructed water tight and deep, and it was customary with us, when we wished to procure an intense heat and a very clear fire, to introduce the water into them in a boiling state. Now Mr. Ivison's modification appears to be merely a substitution of the steam-boiler for the open moistened ashes; in his case the aqueous vapour is admitted from above; in ours, and in a thousand others, I have no doubt it is the same, the steam rises from below, being generated by the ashpit. If he rests his claim on the circumstance of the steam coming from above, the blacksmith opposes him, for this latter worthy with a bundle of moistened rushes in his right hand, throws his steam or condensed steam down on to the fire; and if Mr. Ivison rests his claim on the steam in a rarified state commixed with air as a supporter of combustion, there is scarcely a stoker in England who could not prove it as no invention. Had Mr. Ivison, of the Castle Silk Mills, Edinburgh, been at the cost of expensive apparatus—had he devoted much time, or beyond all, had he evinced considerable tact and ingenuity in his invention, or had he aimed merely to convince his employers, Dr. Fyfe and Mr. William Watson, that he was a very clever fellow, I should have remained silent; but when a plan is proposed, whereby southern plying steamers are to be saddled with an impost of 1*l.* per horse power per annum, I trust they and all others connected with steam will protest against such an undeserved and unearned monopoly. There is a gentleman of considerable talent and ingenuity in all matters connected with gas works, and many others indeed, Mr. Rutter, of the Brighton branch of the General Gas Company's works, who has made some experiments on the assistance water and steam affords to combustion, I call on that gentleman, although I have only once in my life had any conversation with him, and that took place several years since, to communicate whether this principle be Mr. Ivison's discovery or its application new. Trusting, Mr. Editor, that this inquiry may be either speedily answered by Mr. Ivison, or that his pretensions may, by an examination of their merits, be duly estimated, I beg leave to subscribe myself,

Respectfully,

Oct. 2, 1838. A. SOUTHRON, Engineer.

SIR,—On reading in the last number of your valuable publication the account of Mr. Ivison's invention, for saving fuel and preventing smoke, I could not but regret that the parties who had made the experiments had not been more particular in giving the real quantity of steam employed to produce the effects enumerated; I should therefore wish to direct the attention of some of your

* For my part, I wish all large type were melted up, or, at any rate, used only for title-pages, bill sticking, and advertisements. My eyes, certainly, are young and good; but were they otherwise, I hope I should not wish to impose the penalty of large type and dear books upon those who had still to struggle onwards when I had reached the goal. I hope I should then be content to read with spectacles.

numerous readers (whose occupations may permit them) to ascertaining the quantity of steam necessary to be introduced into the furnace for a given weight of fuel to produce the greatest useful effect, and prevent thus the loss of steam which would be occasioned by emitting more than is absolutely requisite. Such a superfluity might probably produce an injurious effect, so that we should be enabled to ascertain the real economy effected by the employment of this valuable discovery.

Another point to which I am desirous of directing the attention of your readers, is the possibility of introducing partially, if not wholly, into the furnaces of the non-condensing engines, steam which is now suffered to escape into the air. The steam which might not be required for this purpose could be introduced at the bottom of the chimney, producing then as in locomotive engines, a greater draught, and doing away entirely with the necessity for such elevated and costly structures as the chimneys now used. By this application also the smoke might be consumed, and a greater draught obtained.

I believe that this would be quite practicable, as the pressure against the motion of the piston will not be augmented, if the tube, which leads to the furnace, be of sufficient diameter, and the aperture large enough to give it free egress; besides, on account of the draught of the fire, it will rush as it were into a partial vacuum.

The advantage of this plan is evident, if there be no practical difficulty to prevent its application, as in this case the saving of fuel would be effected by the use of steam which was before lost; consequently the whole quantity saved is real economy, whilst by letting the steam from the boiler into the furnace, part of the fuel is employed in producing this steam, which is not utilized by the engine, and which must necessarily reduce the real economy considerably.

I take the liberty of transmitting to you these few observations for insertion in your truly excellent journal, should they meet with your approbation, as they may thus fall under the notice of some of your readers who may have the opportunity of applying them; for if the whole economy proposed by Mr. Ivison's experiments were thus realized, it would render the high-pressure non-condensing engines the most valuable.

Yours, &c.,

October 19th, 1838. C. S. M.

THE EFFECT OF GRADIENTS ON RAILWAYS.

(From the Irish Railway Report.)

The term gradient has been adopted to indicate those slight inclinations up which a load may be taken, although with a diminished velocity, without assisting power; being thus distinguished from those steeper slopes, termed inclined planes, where assisting power, either stationary or motive, is intended to be used, according to the general practice of the road; but these latter may still be ascended with small loads by the power of the single engine only, so that, in fact, there is no distinct limit between those slopes and the former; it will, however, be generally understood that a gradient is a slope of small inclination.

If the power exerted by a locomotive engine were wholly applicable to the traction of the load, that traction being a determinate fraction of the weight moved, then in ascending a gradient whose inclination is expressed by a fraction represented by the height of the plane divided by its length, the engine power required for the ascending plane would be to that on the horizontal plane, as the sum of the two fractions (viz., that which expresses the angle of the plane, and that which represents the friction) to that which expresses friction only.

Thus, if, as is commonly the case, the friction and surface resistance is 8lbs. to the ton, or $\frac{1}{280}$th part of the load, then, in ascending a gradient of $\frac{1}{280}$ the required force would be double that for the horizontal plane, and so on for any other proportions. But this is true only of the force of actual traction, and not of the power expended by the engine.

To know the relative engine power requisite in these two cases, we must take into consideration the part of that power which is necessary in order to put the engine itself into a condition to move, that is, the power requisite to overcome the friction of the engine gear, without a load; the surface resistance, and the friction of its own axles and wheels, as well as those of its tender; and lastly, the resistance or pressure of the atmosphere against which the pistons are constantly acting.

These forces together, which must be all overcome by an expenditure of steam power, and a consequent consumption of fuel, before the surplus power can become applicable to traction, amount, as we have seen, to nearly one-third of the whole; and as this amount of absorbed power is the same either on a horizontal or on an inclined plane, the relative force or steam power requisite in the two cases, will be very different from that of the force necessary for traction only, and will vary very essentially according to the amount of the load the engine is employed in drawing, the dimensions of the engine itself, and the inclination of the plane.

In order, therefore, to estimate correctly the effect of gradients on the expense of working a line of railway, we must first inquire into the amount of steam power absorbed in overcoming the resistance to which we have referred. We have not thought it expedient to enter upon these several reductions in the body of the report, but by referring to the note below, the several results derived from them will be found arranged in a tabulated form.

In the note referred to, is shown the amount of duty which a first-rate locomotive engine is capable of performing on a horizontal plane; our immediate object now is to show how much that performance will be reduced on the supposition of certain planes and gradients occurring on the line of way.

We must observe, however, that these reductions will not affect in an equal degree the cases of minimum and maximum traffic; because in the former the duty performed by the engine is not limited by its want of capability, but by a want of due employment; the effects we have traced, therefore, principally apply to cases of abundant traffic. By referring to the note quoted it will be seen that the effect of a gradient in retarding the load, and therefore leading to an additional expenditure of steam power, varies with the amount of the load, the dimensions of the engine, and the degree of inclination. Taking a medium engine and gross loads of 100 tons and 50 tons, that is, including engine, tender, and waggons, it appears that the expenditure of steam power, including the absorbed power, necessary to overcome a resistance of $\frac{1}{280}$th of the load is expressed by $\frac{1}{150}$th of the same, when the gross load amounts to 103 tons, and by $\frac{1}{97}$th when that load is 50 tons. While, therefore, the power of traction is doubled in ascending a gradient of 1 in 280, the requisite steam power will only be increased about one-third with 100 tons, and by little more than one-fourth with 50 tons.

It is important to attend to these facts where only a moderate traffic can be expected, as it will serve to show the impolicy of expending large sums in the formation of great excavations, embankments, &c., in cases of minimum or moderate traffic, although they might be perfectly justifiable where the traffic is likely to be abundant. For, in the latter instance, not only do the gradients retard the speed, and thereby increase the expenditure of steam power, but they have a still more injurious effect by limiting the amount of load which the engine is capable of conveying; it being obvious that a large load, yet such as the engine would be fully capable of drawing along a horizontal plane or medium gradient, might be altogether beyond its power on a plane of certain inclination. In such cases, therefore, a considerable expenditure might be advantageously incurred in the first outlay in reducing the gradients, which would be altogether useless on a line where only a moderate traffic is to be expected.

NOTE.

It is difficult to illustrate and compute the effect of gradients generally, without entering on the subject mathematically, which it is desirable, if possible, to avoid.

A great deal of controversy has taken place in reference to the theoretical principles of this question; but the Commissioners, unwilling to embarrass the Report with controversial matter, have taken the best means in their power to ascertain the actual practical effects of the gradients on the lines at present in operation; and it is on these, and not on any particular theory, the following calculations are founded.

It is agreed on all sides, that the additional force requisite to urge a load up an inclined plane or gradient, is such a fraction of the gross load (that is, with engine and tender included) as expresses the slope of the plane, or the fraction of the height of the plane divided by its length.

The disputed point is, what is gained by the returning load descending the same plane? It has been maintained, that the power which is lost in causing a load to ascend a plane is gained by an equal returning load descending the plane; a deduction, however, which has been controverted by others. Without stopping here to discuss this question, the Commissioners will state the facts they have been able to collect on the subject, and which have been obtained by proposing the following queries to the engineers of the several present existing lines:—

First.—When a plane inclines so much as to give to the engine and load a tendency to acceleration, what is the greatest velocity it is deemed prudent to descend with, in comparison with the usual horizontal velocity? or, to specify more particularly, what velocity would it be deemed prudent to descend with on slopes of $\frac{1}{80}$, $\frac{1}{100}$, $\frac{1}{110}$, $\frac{1}{120}$, &c., supposing the horizontal velocity to be 25 miles per hour?

Second.—What is the greatest slope on which it is deemed prudent to allow of acceleration, and to what amount?

Third.—On medium slopes, what may be considered the excess of allowable descending velocities beyond the mean horizontal velocity?

The answers to these queries were not entirely accordant; but it would appear that no advantage can be claimed for descending planes of greater slope than $\frac{1}{140}$, and that the greatest allowable increase in the descending velocity on planes between $\frac{1}{140}$ and $\frac{1}{250}$ is one-fifth of the uniform horizontal velocity: on less slopes than $\frac{1}{250}$, the gain from descent varies from one-fifth to nothing.

It appears, therefore, that whatever advantage may show itself theoretically on descending planes, there is no practical advantage for those of greater slope than $\frac{1}{140}$; and allowing an advantage of one-fifth additional velocity for planes of less slope than $\frac{1}{140}$, and greater than $\frac{1}{250}$, we are in general on the most favourable side.

It may be said that these descending velocities are obtained with less piston

pressure, which is true; but the steam thus saved in the cylinders is commonly lost at the safety valve, so that there is little, if any saving of steam beyond what has been stated.

One or two cases may now be taken by way of illustration.

Let us suppose a load of 88 tons (tender included) to be drawn along a level plane at the rate of 20 miles per hour, and that this engine and train arrive at a rising plane, sloping 1 in 140; the engine being of the first class, viz., weight 12 tons, and tender 6 tons:—

First, It appears by Table 1, vide Journal, No. 13, page 343, that the power absorbed is . . .	1075lbs.
88 tons, at 9lbs. per ton	792
	1867lbs.,

which is the pressure required on the horizontal plane.

To this is to be added the additional traction necessary to cause the loads to ascend the place; we must now, therefore, add the weight of the engine itself, 12 tons; making the whole load to be raised 100 tons, or 224,000lbs., and $\frac{1}{140}$th part of this is 1600lbs. additional traction. But it has been seen that every 8lbs. traction causes 1lb. additional friction on the engine gear; this makes 1800lbs.: the whole required force now therefore is 3667lbs.; and the velocity being inversely as the pressure, or force of traction, we have 3667 : 1867 : : 20 : $10\frac{1}{5}$ miles, the velocity of ascent: that is, the time of ascending will be nearly double that required to go the same distance on a horizontal plane, but in the return the time of descent will be the same as on a horizontal plane; so that ascending and descending a plane of this slope with a load of 88 tons, will require the same time and power as would be necessary to pass and repass a horizontal plane of one-half greater length; or, calling the length of the gradient 1, the equivalent horizontal plane will be 1.5.

Taking now the same engine and load, and the slope of the plane $\frac{1}{500}$, let it be required to find the equivalent horizontal plane.

Here the absorbed power, as before, is . .	1075
88 tons, at 9lbs.	792
Traction on a level	1867

Tons. Tons.

88 + 12 = 100 tons = 224,000lbs.; this divided by 500 gives 448lbs., which is equivalent to the traction of 56 tons on a level; and this, at 9lbs. per ton, is 504 additional pressure. The whole pressure is, therefore, 2371lbs.; and 2371 : 1867 :: 20 : $15\frac{3}{4}$ miles nearly; and as 1867 : : 2371 : : 1 : 1.26 length of horizontal plane equivalent to the ascending plane. And again, $1\frac{1}{5}$: 1 : : 1 : .83 length of horizontal plane equivalent to the descending plane.

$$\begin{array}{r} \text{Whence, } 1.20 \\ .83 \\ \hline 2.03 \\ \hline \end{array}$$

1.015 mean equivalent plane.

It follows from this, that the lengths of the equivalent horizontal planes depend upon the amount of absorbed power of the engines, and the weights of the loads. In Tables 5 and 6 the length of equivalent horizontal planes are computed for gross loads of 100 tons and 50 tons, with engines agreeing in dimensions with what have been denominated the 1st class engines, and Tables 7 and 8, &c., for the same loads with engines of the 2nd, 3rd, and 4th class.

The tables will furnish criterea for determining the effects which different orders of gradients have upon the working of a line of Railway, the load being given; for, by reducing every length of gradient to its equivalent horizontal plane, it will be seen what length of horizontal plane is equivalent to the whole line.

It is to be observed, however, that the effect thus shown is not all the effect that is due to the gradients and planes; for it is these planes which limit the amount of load. If a line is wholly horizontal, and the traffic abundant, the loads may be chosen so as to bring out the best effect; and it has been seen, that the greater the load within the power of the engine, the greater the economy of working; but when it is required to ascend planes without assistant power, the load must be taken such, that it will ascend the plane with a certain velocity.

The engines are thus obliged to work with small loads, and all the loss attending on such loads must be considered to increase to the above disadvantages.

Thus, for example, in ascending a plane of 1 in 140, with a load of 100 tons, it appears by Table 5, that the force of traction would be doubled, or be equivalent to the traction of 200 tons on a level. In order, therefore, that the engine may ascend this plane without assisting power, it would be deemed necessary to reduce the load, probably to 60 tons; and then again, by referring to Table 1, it appears that all the expenses of haulage are increased 36 per cent.; not only, therefore, is the equivalent horizontal plane about one-half longer than the real length of the actual plane, but the expense of working the whole distance is increased 36 per cent.

This points out the advantage of accumulating the ascents as much as possible into short steep planes, and working these planes by assistant engines either motive or stationary: for although there is really no saving of power by this arrangement, there is a saving of time; and what is of more importance, it will not be necessary to reduce the amount of the loads below what would be otherwise considered as most advantageous for the general traffic. These remarks apply to all kinds of loads; but they refer more particularly to those of heavy luggage, where speed is not so essential a consideration as in the passenger trains.

TABLES showing the Lengths of Horizontal Lines equivalent to the several Ascending and Descending Planes stated in Column 1; the length of the Plane being unity, the Gross Load includes Engine and Tender.

NOTES ON CONCRETE.

BY LIEUTENANT DENISON, ROYAL ENGINEERS.

(From the Papers of the Corps of Royal Engineers.)

Since the publication of the first volume of 'Professional Papers,' circumstances have caused me to pay particular attention to the application that has been made of late years of concrete, or artificial stone, to the various purposes of construction; and I shall now briefly state the experiments that I have made or witnessed on this subject, and the conclusions that may be fairly deduced from the results of these experiments.

The first experiment was made with the view of ascertaining whether a mass of concrete, made with Aberthaw lime, would resist the chemical action of water; for this purpose a small block, which had been prepared for nearly two years, was immersed for some time in distilled water, and upon applying the proper test to the water, it was found to have combined with a portion of the lime in the block. Having mentioned this circumstance to Sir M. Faraday, he suggested that it was probable the block contained a quantity of lime in an uncombined state; and recommended that it should be placed in a running stream for some time, in order to wash it thoroughly; this was accordingly done, by suspending the block for two months under a hulk in the river, after which, having again soaked it in distilled water for a week, hardly any trace of lime could be detected in the water by the application of the most delicate tests. This experiment then appears to prove that concrete, composed of proper materials (hydraulic lime and gravel), does not suffer by the chemical action of water. Experiment No. 2 was made in order to ascertain the strength of a block of concrete 2 ft. 6 long, 1 ft. 6 broad, and 1 foot deep, which had been made for two years, and would have been used as a stretcher in the river wall at Woolwich. A shackle was placed round the centre of the block, and two others at the extremities, at a distance of 11½ inches each from the centre; a force being applied to the two end shackles by means of the hydraulic press, the block broke in the centre, under a strain of 4 tons 11 cwt. I did not prosecute the experiment upon the strength of this material any further, having sent down some blocks to Colonel Pasley, R.E., who was investigating the same subject, and the results of whose experiments are as follows:—

Three stones, each 3 feet long, 18 inches wide, and 15 inches deep, were supported upon props 27 inches apart; weights being then applied to the centre of each, the first broke with 6285lbs., the second with 5141lbs., and the third with 2930lbs. This last had probably some flaw; taking therefore the mean of the two first only, the result will be 5713lbs.

A piece of York paving, 7½ inches deep, 13 inches wide, and the same distance (27 inches) between the supports, broke with a weight of 13,512lbs. The value of the constant S, in these two cases, deduced from the formula $S = \frac{lW}{4bd^2}$, will be for concrete 9.5, and for York paving 124.7, being about in the proportion of 1 to 13.

The experiments I have had the opportunity of witnessing, and which offer by far the most instructive results, have been the practical application of concrete to the construction of river-walls at Woolwich and Chatham; in both these instances M. Ranger's patent concrete has been used. In one instance, at Woolwich, it has been applied in mass, the wall having been constructed in the same manner as the Brighton sea-wall, described by Colonel Reid in vol. i.: in both the other instances, at Woolwich and Chatham, the concrete was formed into blocks, which were allowed ample time to set and harden before they were built into the face of the wall.

At Woolwich the riverwall is for the most part founded upon piles; its height above the piles is about 24 feet, the thickness at bottom 9 feet, at top 5 feet, with a slope or batter in front of 3 feet in 22: the face of this wall is composed of the abovementioned blocks, which are laid in cement, in courses 1 ft. 6 in height, the headers and stretchers in the course being each 2 ft. 6 long, the former having a bed of 2 feet, while the latter have only 1 foot; behind the facing the rough concrete is thrown in to complete the thickness of the wall and counter-forts. Both the blocks and the rough concrete are composed of lime and gravel, in the proportion of 1 to 7, and brought to the proper consistence with boiling water; but the blocks are, or ought to be, made with Aberthaw lime, while Dorking lime is used for the rest of the work. The blocks are cast in moulds, and are submitted to pressure while setting: a coating of finer stuff is given to the face for the sake of appearance. The whole of the wall is built by tide work, and in the lower part therefore the backing of rough concrete has hardly time to set before it is covered by the tide; the water, however, in this instance, appears to affect the surface of the mass only, the interior, at the depth of a few inches, being, generally speaking, dry, and of a moderate degree of hardness when examined after the retirement of the tide.

During the summer the action of the water from day to day upon the facing of the river-wall wast not perceptible; the surface still remained moderately hard; occasionally portions of the fine facing separated from the rest of the block, owing, it was said, sometimes to want of care in the original construction, sometimes to injuries caused by boats or vessels striking the wall: in these cases, however, a new facing of cement was applied, and before the winter the general appearance of the wall was to a certain extent satisfactory.

During the hard frost, however, evidences of failure began to show themselves; and as soon as the thaw allowed a thorough inspection of the face of the wall to be made, it was found that hardly a single block had escaped without some damage; in many instances the whole face had peeled off to the depth of half an inch; and at one spot, where a drain discharged itself into the river from a height of about six or eight feet, the back action of the water after its fall had worn away the lower courses to the depth of some inches: these were the evidences of the action of frost and water combined upon the best constructed wall at Woolwich. At Chatham they were of the same character, but the damage done to the wall was much greater.

The portion of river-wall at Woolwich, which was built with rough concrete, had been severely injured by the common action of the water before the frost; and the latter has only caused the destruction of the face to proceed with greater rapidity. Since the frost I have examined the walls of a school near Blackheath, which was built with concrete some years ago: I found that at the ground line, where the drip of the water had acted, the concrete was soft, and yielded easily to any force applied, while the walls above were very fairly hard, and seemed to have stood very well.

These then are the facts I have to lay before my brother officers; and I think they afford sufficient grounds for asserting, that in climates like ours, in situations exposed to the alternate action of water and air, concrete cannot be advantageously used as a building material, the apparent economy, caused by the cheapness of the material employed, being more than compensated for by the frequency of repairs. From the circumstance that at Chatham some of the blocks remain to a certain extent uninjured, whilst others close to them, and exposed to exactly the same action, are completely decomposed, one would be tempted to infer, that proper caution had not been used in the selection of the lime of which the latter were composed; and that, had Aberthaw lime been used throughout, the damage would not have been near so great; but even in this case, although the frost might not have produced so much effect upon the work, and should concrete be considered perfectly impervious to chemical action, yet the want of tenacity, or of power to resist a very trifling force, renders it peculiarly inapplicable to situations where, as in wharf-walls, it will be exposed to damage from the collision of vessels and floating bodies, in addition to the constant mechanical action of the water; where, however, it is protected from these causes of destruction, as in foundations, its value is unquestionable; and even in the backing of retaining-walls, revetements, &c., it may in many cases be advantageously applied, taking care to allow it time to set before any great pressure is thrown upon the wall. The specific gravity of concrete is from 120 to 130, about the same as that of brick-work.

APPLICATION OF PRICE AND MANBY'S HOT WATER APPARATUS TO DRYING OF TIMBER.

A stove has been constructed for Messrs. S. and J. Holme, very extensive builders at Liverpool, for the purpose of drying timber for floors, and other fittings of houses, &c., by the application of Messrs. Price and Manby's patent warming apparatus, as described in our Journal, No. 10, page 237.* which, with the great number of hands they employ, was a serious inconvenience and loss; they are now fully prepared at all times with a stock of timber perfectly dried, as if by the combined action of sun and wind; and they find the timber is seasoned in a manner much superior to any other method. The dimensions of the stove, in which the timber is dried, are 43 feet long, 11 feet wide, 17 feet 6 inches high; and the cost of the apparatus was about 150l.

An experiment was tried by having a flooring batten, 7 inches × 1¼ inches cut from a piece of timber which had been floated and was as full of water as it could be placed in the stove, and when the temperature was 102° it remained there five days, and when sawed down into ⅝ broad and planed it was found to be perfectly dried throughout. The heat is so gentle and the evaporation so equal, that the timber is never rent, as when exposed to the air and a hot sun; in short, it certainly is the most perfect timber-stove that has been made. It would be invaluable for large cabinet makers, pattern makers, and piano-forte manufacturers.

Annexed is a letter from Messrs. S. and J. Holmes, of Liverpool, relative to the merits of the stove:—

"September 26, 1838.

"Gentlemen,—We have delayed writing until now, that we might give our drying stove a fair trial before we expressed any opinion upon its merits. It has now been filled and emptied three times, and it has certainly exceeded our expectations. The stove holds about 30,000 superficial feet of inch boards, and upon our late system (steam pipes) occupied us nearly a *month* in drying. Your apparatus, with rather less fuel, has thoroughly, dried each stove-full in ten days; thus sparing us considerableextra labour enabling us to expedite our business, and saving us the consumption of twenty days' fuel. The average temperature is 104°; and as the continuous stream of pure air, passing between the metallic plates, is divested of its moisture, it carries off the dampness from the timber in an imperceptible but most effectual manner. We find it a very great convenience, from the superior way in which the timber is dried, and because it will not be liable to shrink in the least. We are satisfied that the apparatus would be invaluable for many purposes in our national manufactures, as it combines efficacy with simplicity. Our yardman and night watchman attend to it successively, and it seems impossible that it can get out of order.

"We are, gentlemen, yours, very faithfully,

(Signed) "SAMUEL and JAMES HOLME."

"To Messrs. Price and Manby, London."

---

* In their large undertakings, Messrs. Holmes found a difficulty in keeping a stock of dry timber.

MONTROSE SUSPENSION BRIDGE.

The suspension-bridge of Montrose has, by the awful storm on Thursday, 4th ult., been rendered impassable. Exposed as it was to the whole force of the hurricane, and from its great length, a very considerable vibration was experienced on the bridge during the afternoon and evening; and at twenty minutes before seven, a large portion of the platform, or roadway, started and sunk, with a report resembling that of distant thunder. Portions of the wooden material of the bridge have been washed on to Rossie Island. It is ascertained that no person passed through the toll on the south end immediately previous to the accident, and we fervently trust there had been none from the north. The mail from Aberdeen, which arrived in rather less than an hour after it was due, was detained in town during the night. Sorely tried as the chains of the bridge must have been, they have stood firm, and do not appear to have sustained the slightest injury.

The appearance of the bridge on Friday morning after the accident proved that we had underrated the extent and nature of the catastrophe. The structure, as most of our readers know, is suspended by four main chains, which were recently strengthened by additional links, and rest on massive stone towers, 72 feet high, 39½ wide, and 20 feet in thickness at the level of the roadway, and at the top 32 by 12. The distance betwixt the suspension towers is 432 feet; and the bridge thus presented one vast and beautiful span, over a deep and rapid river, unequalled in extent by any similar erection in Britain, excepting the Menai Bridge. The entrance to the bridge at either side is by an archway in each tower, 18 feet high by 16 feet wide. The platform, or roadway, was laid upon cast iron beams, suspended from the main chains by perpendicular iron bars or tension rods, about five feet apart. On the occasion of a westerly gale, the bridge has been frequently observed in a kind of undulatory motion: but on Thursday afternoon, about dusk, it rocked like a vessel tossed by an angry surge, and at the height of the storm the platform separated nearly at the centre, and, to the extent of about 130 feet, was almost instantaneously torn up by the violence of the hurricane, and disappeared in the highly agitated waters below. The main chains, indeed, had stood firm; but almost all the tension rods were twisted and bent from their position, and many broken; and, independent of the large portion of it carried away, the platform had, by the extraordinary vibration of the bridge, been detached six or seven inches from the stone work at each end. Portions of the wrecked roadway were on Friday morning still suspended by the chains, and hung downwards to the river; while the remaining parts are bent and inclined seemingly according to the pleasure of the rods. The dreary aspect of this magnificent work gave silent but powerful admonition of the ease with which the strongest and most beautiful works of man can be riven and shattered and trampled beneath the power of the elements, when their strength is put forth in wrath. Temporary accommodation for the mail and other coach horses has been provided on Rossie Island; while the passengers, &c., are conveyed by ferry-boats; but it is believed that a road for pedestrians may speedily be constructed over the breech in the bridge without much difficulty.—*Montrose Review.*

NEW WATER COCKS, HIGH PRESSURE STEAM AND OTHER COCKS.

Fig. 1. Elevation.

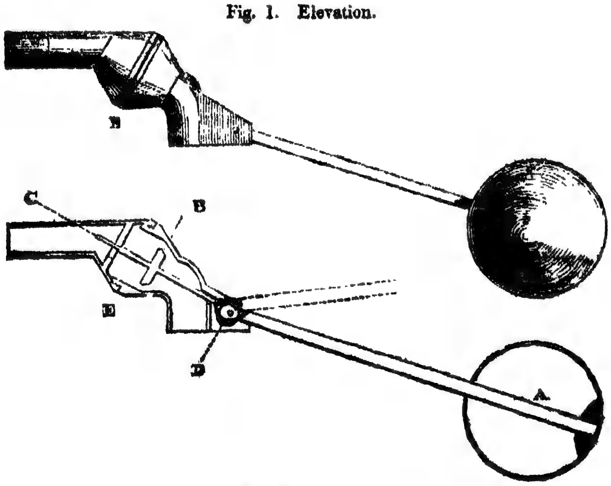

Fig. 2. Section.

Mr. Henry R. Abraham, of Torrington-street, Russell-square, has patented certain inventions by which adhesion, leakage, and difficulty of action in cocks, is overcome; and, as they are novel in their form and action, a description of them may be acceptable to those interested in this important branch of fluid apparatus.

The first that comes under notice is the service or ball-cock for cisterns and of this we annex an engraving, reserving for a future number the description of the other and equally important contrivances.

A new ball-cock has long been a desideratum, for certainly no article in common use, with so many defects, has met with an equal share of toleration. For this we have been indebted to those who find half-a-crown for occasionally *oiling* and *easing* a fruitful source of profit, and the occasion of many another little snug emolument, such as the detection of faults in cisterns, which otherwise might have remained for ever undetected, and the new leathering of valves which, had not the ball-cock been "seen to," might have remained unmolested for ages. In fact, the ball-cock is the plumber's best friend; and no improvement will ever supersede it, unless the architect and builder become parties to its banishment.

That which is required in a ball-cock is certainty of action, rapidity of delivery, simplicity of parts, and durability of construction. Of these requisites not one is possessed by the common ball-cock.

Figure 1 is an elevation, and figure 2 a section of Mr. Abraham's apparatus. Figure 2 is a small ball, sufficiently buoyant to float the power necessary to throw back the valve B, when the service of water is on at the highest possible pressure. The valve is here shown open, or thrown back by the depression of the ball, and in this situation it is held so long as the spindle C infringes upon the eccentric D. The ball, floating, slowly relieves the spindle, and allows the pressure of water flowing in to close the valve, the greater the pressure the greater being the security, while the smallest possible head of water suffices to stop the supply. From the cut, it is obvious that no action occurs until the float reaches above the line of the cock. Thus the cistern is filled with a stream equal to the whole capacity of the pipe to the very brim. In this manner the greatest possible rapidity of supply is obtained. The other qualities are also obtained, as from the construction no sticking can occur, there being no extent of surface in contact. In the event of any obstruction occurring from dirt or weeds, a casualty not probable, by unscrewing the parts at E, the most uninitiated may remove the defect. Of its simplicity there can be no question. A great advantage of such an apparatus as the one before us is, that in using it much smaller pipes will suffice than those usually employed, and a great saving as well as greater neatness of execution be effected. For instance, a half-inch service pipe will fill a cistern in one-third the time now taken by the three-quarter cock and three-quarter service; and if there be 20 feet of pipe from the main, the difference in expense, with joints included, will amount to more than the price of the article, and a large sum is saved in the greater capacity of the cistern. Why plumbers now fix three-quarter service pipes to cocks which only deliver about a fifth of the quantity that a three-quarter pipe will supply, is a trade secret; and why cock-founders make the cocks with three different capacities of orifice, the middle one discharging about a fourth the quantity of the bore, is another secret. But architects and engineers allow it, and the best cock-founder is he who can work the most lead in his metal, substitute most grease for grinding, and charge less per dozen than other houses in the trade. The profit to the plumber is largest on the worst article. Thus the trade price of a three-quarter ball-cock is 30s. per dozen; copper balls, 1s. 8d. each; boss, 6d.; cement, solder, and labour for joints, 1s. 2d.; so that the whole, fixed, costs six shillings, while the price charged by the plumber is seldom less than 16 shillings.

We do not intend to stigmatise the trade in general by these remarks. There are many honourable men who spare no cost on their work, and obtain too often no better favour than the scamp who fixes the worst apparatus, and claims the highest reward.

TUNNEL UNDER THE THAMES AT GRAVESEND.

An Act of Parliament was obtained in 1799, containing 65 clauses, to authorise the construction of a Tunnel under the Thames from Gravesend to near Tilbury Fort.

Capital 30,000*l.*, in 100*l.* shares, with permission to raise 20,000*l.* more, if required. No tolls were to be taken from the military on march, or for military stores, for which exemption the Government was to pay to the company the sum of 1,000*l.* per annum. The company to pay to his Majesty the sum of 80*l.* per annum, for compensation for injury done to the ferry, which is the property of the Crown, and a like rent of 30*l.* to the corporation of Gravesend, for injury done to their portion of the ferry.

Mr. R. Dodd was the projector. His tunnel was to be 16 feet diameter in the clear, and was to be illuminated with lamps (gas not being then known). His estimate was as follows:—

900 yards of running measure of tunnelling, digging, and vaulting, with key stones, at 12*l.* per yard	£10,800
Relaying the bottom with new-made ground, 900 yards, at 1*l.*	900
Fixing lamps and irons through the tunnel, toll collector's room, gates, &c.	400
Making good entrance roads at each end	160
Steam engine and pipes, if necessary	1,780
Necessary machinery during the execution	500
Ten per cent. on the whole for contingencies	1,455
Total	£15,995

The work was estimated to be finished in 12 months.—I believe the work was begun and carried on, although slowly, for upwards of three years.

S.

The late great Fire at Liverpool.—From the official report of the fire-offices relative to the extent of the insurance on the property destroyed at the late calamitous fire at Liverpool, it appears that nearly the whole is covered by the following amount of insurances:—Liverpool Fire Insurance-office, 24,000*l.*; Royal Exchange, 22,000*l.*; Sun, 19,000*l.*; Manchester, 14,000*l.*; West of England, 13,000*l.*; Phœnix, 7,000*l.*; London, 6,000*l.*; York and North of England, 5,000*l.*; Guardian, 4,000*l.*; Scottish, 3,000*l.*; Yorkshire, 500*l.*; Alliance, 2,000*l.*—Total, 119,500*l.* The extent of the loss was estimated at 120,000*l.*—*Evening paper.*

DIMENSIONS OF SUSPENSION FOOT BRIDGE OVER THE RIVER THAMES,

FROM HUNGERFORD MARKET TO BELVIDERE ROAD LAMBETH, AT THE PART AT PRESENT KNOWN AS "SMITH'S WHARF," NEAR THE CORNER OF SUTTON STREET. ENGINEER, I. K. BRUNEL, ESQ. CONTRACTORS, MESSRS. GRISSELL AND PETO, LAMBETH.

	Feet	In.
Length in clear of the Land Piers	1400	0
Width of Roadway	14	0
Span of Centre opening, from centre to centre of Piers	600	0
Versed sine of do.	50	0
Width of two Water Piers, each	19	0
Span of side opening, from centre of Piers to Abutment	400	0
Height of Roadway above high water mark	29	3
Height of Suspension Piers above Roadway	62	9
Total length of Chain, from extremity of Land Tie on North side, to extremity of Land Tie on South side	1600	0
Average length of Links, from centre to centre 24 to	25	0
From high water mark to seating of Chains on Piers	82	0
Radius of curve nearly corresponding to the curve of the Chains	925	0
Difference of Level between the points of support	53	0
Length of Land Tie (North side)	70	0
Length of Land Tie (South side)	105	0
Rise of Floor from abutments to centre	8	6

Total number of Links for Chains . 1680

500 $1\frac{7}{8}$ inches thick		for the lower part
500 $1\frac{7}{16}$	"	
340 1	"	for the extremities.
350 $1\frac{3}{16}$	"	

All the Links to prove to 10 tons on the inch.
Suspending Rods, $1\frac{3}{8}$ in diameter.
Amount of contract, about £85,000.

CYCLORAMA.

A most extraordinary exhibition, under the above title, is about to be opened by subscription. It will consist of a revolving picture, 120 feet in diameter and 40 feet high, upon the principle of the Diorama. The artist is the Chevalier Bouton, who has been so successful at the Diorama. The machinery is to be constructed under the superintendence of Mr. Bradwell, of Covent Garden Theatre.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL GEOLOGICAL SOCIETY OF CORNWALL.

The twenty-fifth annual meeting of this society was held on Tuesday last at Penzance, the President, Davies Gilbert, Esq., D.C.L., V.P.R.S., in the chair.

TWENTY-FIFTH ANNUAL REPORT OF THE COUNCIL.

On presenting their twenty-fifth Annual Report, the Council have to communicate the gratifying information that her Majesty the Queen was pleased to receive the address of congratulation and condolence from the Society in the most gracious manner, and to signify her intention to comply with the wishes of the Society, by becoming its Patroness.

The Map (of what may, perhaps, not improperly be termed the surface Geology) of Cornwall, executed by Mr. De la Beche, and the illustrative Memoir by which it is to be accompanied—anticipated in the last Report—have not yet appeared.

Unforeseen circumstances, chiefly on the part of the printer, have delayed the appearance of the fifth volume of the Society's Transactions; but a considerable portion of it, embracing a large part of Mr. Henwood's Memoir on the Mines of the County, on which he has been more or less occupied for twelve years past, is now on the table; and the surveys being all completed, it will be published in the early part of the ensuing year.

Dr. Boase has been compelled to delay his Memoir on the diluvium and other transported matter of Cornwall: but it is only deferred, not withdrawn, and will occupy a prominent place in the next volume of Transactions.

The donations to the Museum and Library, during the past year, have not been very numerous, but in value they have not been often exceeded.

The Council also notice with peculiar satisfaction the interest shown in the advancement of the Society by the practical miners of the county.

The establishment of an Academy for instruction in the Arts and Sciences connected with the mining in Cornwall, has been a long cherished object of the Society; but it is obvious that such an institution is not likely to be formed, until the mining interest in general shall be convinced of its utility and nesessity, and shall express their opinion in its favour. The council rejoice in the belief that this conviction is increasing; and that it will not be long before, either by the establishment of a kind of experimental college, or by the periodical visits of the principal professors of the arts and sciences connected with mining, the reproach which has been long and deservedly applied to Cornwall, or rather to England—that, with the richest and most instructive mining field in Europe, it is behind almost every other nation in furnishing scientific information to its mining population in general, as in providing the means of leading those on whom the management of the mines principally depends, into the higher parts of the sciences which bear upon the theory and practice of mining—will be entirely wiped away.

During the meeting of the British Association at Newcastle, a committee was appointed for the purpose of assisting different mining districts in an united effort to originate a school for instruction in the arts and sciences, connected with mining, on an enlarged scale; and the Council embrace the present opportunity of calling on the members, and all who are connected with the mining interests of this country, and the interests of science generally, to use their best exertions to promote so important an object.

Among the papers which had been read since the last report were the following:—

Notice of a raised Beach immediately under a part of the town of Penzance. By Joseph Carne, Esq., F.R.S., &c.

On the Assaying of Copper Ores by means of Galvanism. By Martin J. Roberts, Esq.

On the expansive Action of Steam in the Cylinders of the Cornish Pumping Engines. By W. J. Henwood, F.G.S.

ROYAL CORNWALL POLYTECHNIC SOCIETY.

The anniversary of this institution was celebrated in their hall at Falmouth, on the 2nd, 3rd, and 4th instant, and surpassed all its predecessors both in numbers of attendants and in the importance of its objects. This institution is formed on the basis of the Society of Arts in the Adelphi, and distributes annual premiums for simi'ar objects. One great feature of it, and one deserving of attention, is the very great share that ladies are allowed to take in its proceedings, and, it appears, with complete success. In the departments of the Fine Arts, the ladies carried off a great many prizes, and some in departments which they do not generally cultivate.

After an address from the chairman, the venerable Davies Gilbert, the several premiums were distributed to the successful competitors.

A premium of ten guineas, by Sir Charles Leman, Bart., and R. W. Fox, Esq.; for the best reports of a series of experiments made with the wedge for blasting rocks, invented by R. W. Fox, Esq.; awarded to Captain Richard Dunstan, of Wheal Vyvyan mine.

A premium of ten guineas, by G. C. Fox, Esq., for the best essay on the various diseases incidental to miners, their cause, and the best practical means of remedying them—any statistical information as to their longevity, compared with that of the other population of the county, is deemed highly desirable; awarded, in terms of high commendation, to Richard Lanyon, Esq., of Camborne.

A premium of ten pounds, by John Hearle Tremayne, Esq., for the best available method or improvement on the plans already suggested for facilitating the ascent and descent of miners; awarded to John Phillips, of Halsetown—on account, however, of its merits underground—the judges not being prepared to recommend in equal terms the machinery to be employed above.

Several other premiums for models were then distributed, and others announced for competition in the ensuing year. Among these was one by Charles Fox, Esq., for such instructions for a general and particular examination of every steam-boat engineer as may place beyond a doubt the candidate's capability to undertake a charge of such great importance, either in long or short voyages, in fine or stormy weather, and when the boilers and machinery are in order, or when some parts have received injuries not irremediable at sea, or at least not incompatible with the use of steam during the remainder of the voyage. The competitors for this premium must forward their papers free of expense to the Secretaries within nine months from this time. The general committee will have the power to award the premiums at that time, and will be at liberty to prepare a compilation from the papers successfully competing. The most concise examination, in which nothing of real importance shall be omitted, will be preferred.—£7 7s., £5 5s., £3 3s., and £2 2s.

A premium to the amount of £350, was offered by Charles Fox, Esq., and other gentlemen, to the first mine which should adopt the principles of any of the Society's machines for raising the miners from their work.

After some other incidental business, the President observed that five or six other societies had been formed upon the model of this. He believed he need not inform the meeting that this society owed its origin to two young ladies, at that time not twenty years of age, supported indeed by the judgment and liberality of their relations, who were well known to all present, and whose reputation extended from one end of Europe to the other.

The Secretary then read a letter from a working miner to J. S. Enys, Esq., on a mode of extracting copper from mingled copper and tin ore by the aid of sand; after which

R. W. Fox, Esq., made some remarks on the ascent and descent of miners at King William mine, in the Hartz, by machinery similar to that which had on that day received their award. So highly was it appreciated by the workmen, that men employed forty fathoms above it, and at three quarters of a mile distance, preferred coming to it, to ascending by ladders from the spot where they were working. He then gave a short but very interesting lecture, as we may well term it, on the formation of mineral veins by electricity, in illustration of which he exhibited the result of various experiments.

On Wednesday the 3rd, the hall was opened for the exhibitions, and the minor prizes were distributed. Among these were a safety apparatus for a steam-boiler, by S. Hocking; copper-house, Hayle; model of Penzance Market House, &c. The ladies carried off prizes for amateur oil painting; drawings in water colours; pencil, crayons, and pen and ink, engraving, and etching; architectural drawings, &c. They also gained prizes for an herbarium of foreign plants, and a collection of lichens.

INSTITUTION OF CIVIL ENGINEERS.

Report of Papers read and Proceedings, Session 1838.

(Continued from page 348.)

Explosion of Steam Boilers.

Mr. Lowe stated that the ordinary process of making water gas showed that an iron plate would readily decompose steam or water. The decomposition of water goes on extremely well until the oxidation of the tube has advanced to at least $\frac{1}{16}$ths of an inch. An iron tube begins to make gas extremely fast at first, and continues until the tube is cased with a thick crust of protoxide of iron.

Improved Levelling Staff.

Mr. Bruff exhibited an improved form of Levelling Staff. The figures on this staff are inverted, so that when viewed by an inverting telescope in the usual manner, they appear erect, and are read off without any danger of mis-mistake; which may readily occur when some figures, as, for instance, 6 and 9, are read off inverted. The mechanical arrangements for extending it are with the view of securing greater steadiness. The principal improvement consists in there being attached to the bottom an universal joint, fixed to an iron plate; this plate remaining fixed, the necessary errors consequent on moving the staff for reversing its face, when the last forward station is to become the next back, are avoided.

It was suggested that the universal joint would be attended with great advantages in sloping ground; in general, however, the tripod invented by Mr. Simms was sufficiently convenient.

Mr. Bald suggested that the universal joint would be extremely serviceable if placed on something solid. It was his practice to drive a wooden plug into the ground, on which the staff was set; these plugs were left in, and serviceable for verifying the observations. He had levelled through a distance of forty miles, leaving a plug at every station.

Experiments on the Flow of Water through pipes of different lengths. By W. A. Provis, M. Inst. C.E.

In this paper are recorded *two hundred and eight* experiments on the flow of water through leaden pipes of $1\frac{1}{2}$ inch diameter, of lengths 100, 80, 60, and 40 feet, and for heads of water of 35, 30, 24, 18, 12, and 6 inches. The arrangement of the experiments is described with great accuracy, and the results of the experiments are given in twelve tables, showing the length and inclination of the pipe, the head of water at the upper end of the pipe, the time from turning the water into the upper end of the pipe to its reaching the lower end, the time of filling the receiver, the discharge in cubic feet per minute, and the mean discharge per minute. To each set of experiments is appended a column of remarks, in which the state of the pipe as to dryness, and the quantity of water in the discharging end, are recorded; these circumstances having considerable influence on the quantity of the discharge.

The experiments are tabulated in a different form, showing the effect of a given head of water in pipes of different lengths and inclinations. The following important results are deduced. In level pipes the quantity of water discharged is nearly in the inverse ratio of the square root of the length; but the departure from this rule is greatest in the shortest lengths and greatest heads. In inclined pipes, the increased discharge is greater in the long than in the short pipes. The increased discharge for an increased head is nearly in the same proportion through the long and short lengths.

Table of Gradients. By C. Bourns, A. Inst. C. E.

per mile.				per chain.		per mile.				per chain.

Description and Drawing of the Ice Boat. By S. Ballard, A. Inst. C.E.

The principle of breaking ice adopted by Mr. Ballard, as explained in a communicaiton made last session,* consists in forcing the ice upwards instead of forcing through it horizontally, or by pressing it down. For this purpose a frame, coated with sheet iron, is laid over the front of a boat, with an inclination downward from the boat, the lower end being under the ice. The paper describes the construction of the boat by reference to a detailed drawing and section.

On the Construction of Roads on Deep Bogs and Moss. By W. Bald.

In this paper the author gives a detailed account of the construction of roads through bogs, and of the methods of securing the foundations of small bridges in boggy places; also some suggestions on the formation of railways on deep moss.

The general principles are as follow:—The first operation after laying out the line of road is to drain thoroughly the bog over which it is to pass. For this purpose main drains and counter drains parallel to the line of road are to be cut with a regular discharging fall along the bottom. Transverse drains must also be cut betwixt the main and the counter drains, so as effectually to drain off all the surface water and stagnant pools. The cutting of these drains must be carried on gradually, and by degrees; if the bog be moist, the operations, which can only be carried on at dry seasons of the year, will probably have to be continued over three or four years before the drains become permanently fixed at the required dimensions. The counter drains are essential, as they relieve the pressure on the sides of the main drain, and consequently prevent it filling up. The bog stuff cut out is to be dried, and when the bog under the line of road has become sufficiently dry, the road is to be levelled, and made of proper shape, and the cross drains are to be filled with dry turf.

The road-way is then to be floored or trunked over with five courses of dry heathy sods, which are to be well rolled with a heavy cylinder. Upon this trunking is to be laid a soling, consisting of a mixed mass of prepared earth and gravel, of about six inches in thickness, and the whole to be coated with good clean gravel. The road metal is then to be laid on, in two successive coats, each of about three inches in thickness, the first being well consolidated before the second is laid on.

The great points to be aimed at are perfect drainage and good trunking, as, if these are not attained, roads constructed on bog will lose their shape, become ruinous, and soon go to decay.

The author considers the form and size of hammers employed in breaking hard stones.

These are frequently too heavy; a hammer weighing about a pound and a quarter, of an elliptical form, pointed at the ends, the area of end being about $\frac{1}{16}$th part of a square inch, appears to be best suited for ordinary purposes.

The turf of bog, being carbonized, makes excellent fuel, and may be employed in the manufacture of iron, and such iron is extremely malleable. Turf fuel is also used most extensively in working the steam engine in many districts of Ireland; it is used on board the Dunally steam boat, for engines of eighteen horse power, and the expense is fourpence per mile.

A communication was read from Mr. Buck on the relation betwixt the diameter and intermediate spaces of the tubes in a locomotive boiler, for the production of an maximum effect in the generation of steam.

[*End of the proceedings, Session* 1838.]

ACADEMY OF THE ANTIQUE,

73, Margaret-street, Cavendish-square.

This institution has been formed by Mr. Fletcher and Mr. Loft, both artists of considerable reputation, to supply that deficiency which exists of a gallery for the study of the antique. It consists of a figure academy, and ladies' academy, to which is proposed to be added, a life academy, while the scale of charges is so moderate as to be considered too low. The figure academy now in operation is established in a lofty and spacious apartment, with walls of a good ground, something of a salmon colour, and most effectively and brilliantly lighted by a chandelier, with a reflector and eight large gas burners. In this academy are arranged numerous figures from the antiques, among which we observed the Apollo, Venus, Fighting Gladiator, Boxers, Antinous, Genio del Riposo, Germanicus, Genius of the Vatican, &c. There is also accommodation for anatomical lectures. The studies are proposed to be principally devoted to the antique, but good modern works are not intended to be excluded; indeed we noticed a rare work by Michael Angelo, a head of Brutus, which excited in the strongest terms the admiration of Sir David Wilkie. The instruction is under the direction of Mr. Villalobos, who has studied extensively in the academies abroad, and we feel happy to bear testimony that the system on which he proceeds, as it is that adopted in our most enlightened schools and on the continent, admits of no doubt as to its success and efficiency. Among the pupils, and it is there that you must look for the proper estimation in which a master is to be held, we observed some elderly artists, others younger, and several amateurs, including one or two civil engineers.

This institution has met with the approbation of all who have visited it, including some of the first artists and connoisseurs of the day, and justly, on account of the unequalled facilities which it affords; and we recommend our readers to go and visit an institution where the courtesy of its directors will make them welcome. The figures are supplied as they are wanted from the gallery of Messrs. Loft (late Sarti), Dean-street, Soho, modellers to the Government, where they have also a school, who have the most extensive collection of casts in this

* See "Minutes of Proceedings," Jan. 31, 1837.—Journal, No. 2, page 26.

country, including most of the antique and modern figures, the Elgin, and the British Museum. Thus the student has access to treasures which are not possessed by any other institution except the Royal Academy, and there, on account of the want of accommodation, the casts are not all available, while the professional nature of the institution precludes its being accessible to the public. In the Margaret-street school, however, the amateur, as well as the artist, can have access to works no where else to be found, and we can confidently assert that it will not only prove a most valuable auxiliary to the Royal Academy, but that it must already take rank before any of the provincial schools of drawing, whether at Dublin, Edinburgh, or elsewhere, and even before most on the continent.

We fully concur in the high opinions which have been expressed of its merits, and we trust that the success which cannot fail to attend it, from its treasures of art and excellent lighting and accommodation, may be such as to enable its public-spirited promoters to persevere until they succeed in establishing what is so much wanted, an accessible school for studying the antique, the living, and the dissected figure.

LAW PROCEEDINGS.

RATING OF RAILWAYS FOR PARISH RATES.

On Wednesday, the 17th October, an adjourned Petty Sessions was holden at Wandsworth, before the magistrates, J. Notridge, Esq., in the chair, for the hearing of appeals against the new assessment for the relief of the poor in the parish of Battersea.

The rating has just been completed, under a survey and valuation made by Mr. Lee on the part of the overseers, and the appeals against it appeared to be numerous,—they were stated to us to be as many as 40. The most important was the case of the Southampton Railway terminus, which is at the extremity of this parish. The rate was as follows:—

Terminus and depôt.—Extent, seven acres.; gross rent, 2,700*l.*; rateable value, 2,000*l.* per annum.

Against this rating the directors of the railway gave notice of appeal on general grounds.

Mr. Bircham, the solicitor of the company, appeared for the appellants; and Mr. Field on the part of the parish.

After a few general remarks upon the law of the case, Mr. Bircham called the architect of the company, Mr. Tite, who stated, that he had surveyed and valued the premises; and that, in his judgment, the annual gross rent was 1,445*l.*, and the rateable value 1,218*l.*; that this was a fair assessment under all the circumstances; and a fair interpretation of the law, so far as he could understand it, as it could be made to apply to this case; but that if the mere dry value of the rent of the land and buildings was to be sought for, from an accidental taker for some general business, as that of a brewer, distiller, dyer, or any similar trade, it was not probable that even 500*l.* per annum could be obtained.

On cross-examination Mr. Tite stated, that, as architect, he had only erected the main building, containing the offices, waiting-rooms for passengers, board, secretary, and engineer; and that of them he knew the cost; but that the great arrival shed, smithery, coach-houses, and locomotive-engine sheds, were constructed under the direction of the engineer, Mr. Locke, by workmen employed by the company upon their general works upon the line, and that the cost could not be separated; but that, in his opinion, all the buildings together, including the boundary walls, could have been erected for, and did not cost more, than 27,750*l.*; and that this did not include tenants' fixtures, nor rails, nor machinery. On which point it was admitted by Mr. Field, that tenants' fixtures were not rated in the parish; though in some cases, as in the instance of a mill, machinery was assessed.

The witness further stated, in explanation of the principles of his valuation, that in other appeals and assessments for tithes and rates upon large public buildings in which he had been concerned, or with which he was acquainted, and when the market value to let could not be ascertained, it had been proposed to take a per centage on the cost of the buildings, which, added to the value of the land, might be assumed as a fair assessment of annual value. That for the reasons that public buildings for public purposes were necessarily more ornamental in their character, and larger in their dimensions, than private ones, and that as a good deal of the outlay, in this particular instance, had been made for the mere convenience of the public, beyond the necessities of the case, 4 per cent. upon this amount had been considered a fair and just rate of charge; and that this per centage, added to the value of the land, had been assumed as a gross rent, and proposed as the basis of the rateable value. That, pursuing this principle, 4 per cent. on the 27,750*l.* would give an amount of 1,110*l.* per annum, to which, by adding 25*l.* for an old stable building (making a total of 1,135*l.*), and deducting 20 per cent. for the outgoings, as directed by the Act of Parliament (viz. repairs, insurance, land tax, and other landlord's liabilities), a net rent of 908*l.* would be obtained. Thus, by assuming the value of the seven acres of land at 30*l.* per acre as a building land, and an additional value of 100*l.* per annum for a water frontage to the wharf, a total of 1,218*l.* would be obtained, as previously stated.

This witness was cross-examined at great length, but nothing appeared to call in question the facts or reasonings deposed to by him. He admitted that the profit expected by a builder on buildings erected for others was 5 per cent. on the outlay; but explained that this could not be assumed as the rateable value, because the value of any house or premises to let might be greatly increased or diminished by other circumstances.

Mr. James White Higgins, Surveyor to the Commissioners of Woods and Forests, and Mr. D. R. Roper, confirmed the testimony of the previous witness, Mr. Tite; and Mr. Higgins stated, that he had been concerned with that gentleman and Mr. Hardwick in the appeal of the Birmingham Railway Company against the rating of the parish of St. Pancras, when the rate of 10,000*l.* had been reduced to 7,300*l.*, in a much lower rate of interest than 4 per cent. on the building, because of the highly ornamental character of the buildings, the portico alone having cost 40,000*l.*

In reply, after some able remarks, Mr. Field called Mr. Lee, who stated, that in his valuation for the parish he took the outlay at 30,000*l.*; which, at 6 per cent., gave 1,800*l.* as the rent of the buildings; that to this he added 500*l.* for the land, which he valued as building land at 40*l.* per acre, and added 220*l.* for the river frontage, being at the rate of 35s. per foot; that to this he added, agreeably to the circular of the Poor Law Commissioners, 400*l.* for the tenants' rates—which, in Battersea, amounted to 4s. 6d. in the 1*l.*—making a total of 2,700*l.* as the gross rent. From this, for the net rent, he deducted the 400*l.* back again; and an additional 300*l.* for repairs, landlord's taxes, insurance, &c., being 18 per cent. on the gross rent of the buildings; making the net annual value for assessment 2,000*l.*

On cross-examination this witness admitted that he had never before been concerned in rating buildings of this character; and in answer to a question from the Bench, he stated, that if a manufacturer had expended 30,000*l.* in erecting a mill, he should rate that at 6 per cent. upon the outlay.

Mr. Nelson, another surveyor, confirmed this statement, only that he valued the water frontage at 2*l.* per foot, and thereby increased the rate. Mr. Nelson stated, that he had been concerned in valuing the parish of Lambeth, and that 6 per cent. on the outlay had been assumed as the basis of similar rating there. On cross-examination he admitted that he knew of no case in which 2*l.* per foot was paid as the rent of any wharf in the parish or its neighbourhood.

Mr. Bircham replied in a speech of much ability, and the magistrates, after deliberating for about half an hour, amended the rate to a gross rent of 2,000*l.*, and a net rent of 1,500*l.*, adjudging each party to pay their own costs.—*From a Correspondent of the Railway Times.*

STEAM NAVIGATION.

NAVIGATION TO INDIA BY THE CAPE OF GOOD HOPE.

A steam vessel now building by Messrs. Scott, Sinclair, and Co., of Greenock, who are also building the engines, has been purchased by the East India Steam Ship Company, as their experiment ship for the voyage from London to Calcutta direct, by the Cape of Good Hope. The vessel and engines are in such a forward state as to warrant the presumption that the first voyage will be made early in January next.

The dimensions of the vessel and engines are:—

	Ft.	In.
Length, from stem to taffrail	200	6
Ditto of keel	189	0
Clear beam midships	32	0
Breadth over the sponsons	48	0
Ditto over the paddle boxes	48	0
Depth of hold	28	0

The main saloon will be 50 feet long by 18 feet wide in the clear, leaving a range of state rooms on each side, opening upon the saloon. The height under the beam will be 8 feet. It is intended to do away with all deck houses or any erections on deck by putting a flush deck on her, which will have the double advantage of giving great accommodation and carrying away those unsightly projections from the deck, which greatly impede the way of the vessel by offering resistance to the wind. When this deck is added she will be equal to 1,200 tons measurement. She is built in a very superior manner, of the best English oak and American elm, copper fastened, and the two bottom planks diagonally bolted, independent of the keel. She is very strongly braced diagonally with iron braces, and her floors are close built and caulked.

The two engines are very strongly and compactly constructed.

	Ft.	In.
The diameter of the cylinder is	0	63
Length of stroke	5	9
Diameter of paddle shafts	0	12½
Diameter of paddles	26	6
Width of paddles	8	0

Number of strokes, 20 per minute.—Paddle float in 3 pieces.

The naves of the paddles are of wrought iron, so rivetted together as to combine great strength with compactness and lightness.

The vessel and machinery are now fitting up under the inspection of Lieut. Kendall, R.N., and Mr. Charles Manby, the commander and inspecting engineer.

Launch of an Iron Ship.—On Thursday, the 18th ultimo, the first iron ship built in Liverpool was launched from the building-yard of Messrs. Jackson, Gordon, and Co., the builders, near the Potteries. As a model this ship is a beautiful thing. She has somewhat of the American build about her bows, has great breadth of beam, and a fine run. With the exception of her decks she is entirely built of iron. She is 271 tons old measurement, 24ft. 6in. breadth of beam, 13ft. 10in. depth of hold, and 96ft. keel, and has 99ft. 9in. for tonnage. All being ready, at 11 o'clock the dagger was knocked down, and the beautiful vessel, with all her masts and rigging up, glided majestically into the river. She was christened the "Ironsides" by Captain Mitchell, formerly of the ship Abbotsford, who is to sail her. It is understood that she is for the Brazil trade. When in the water she floated like a cork, and her masts were as stiff and steady as possible.—*Liverpool Standard.*

The Liverpool Steam Ship sailed from Liverpool on Saturday afternoon, the 22nd ult., on her first voyage to New York. She carried out between fifty and sixty cabin passengers, 150 tons of fine goods, at five guineas per ton, and thousands of letters, papers, and parcels.

Launch of the Archimedean Steam Vessel.—On Thursday, the 18th ult., a steam vessel named the Archimedean, built upon a new principle, was launched from the yard of Mr. Wyan, of Mill-wall, nearly opposite Deptford. Although it had been announced that the vessel would leave the slips at noon, it was half-past one o'clock before the word to "let go" was given. It was then nearly high-water, and the Archimedean glided gently on to the bosom of Father Thames. She was afterwards towed down to Blackwall by the Victory steamer, to have her fittings immediately completed. The principle upon which the vessel is proposed to be propelled is one which has long been in agitation, and which has already been experimentally tried with considerable success upon a vessel of eight tons, and of four-and-a-half horse power, and the objects which it is desired should be attained are at once speed, and the ready application either of steam or sailing power. With a view to attain this end the engine will be placed amidships, as in the steam vessels now in use, and the propeller or paddle, which is under the stern, will be worked by a communicating shaft, acting upon a screw, called the Archimedean screw, in the application or use of which the invention is grounded. The propeller being placed under the stern, the inconvenience arising from the paddles now in use, which act themselves as a back water, is avoided, and great benefit will be derived in seas when the wind is on the beam, when, instead of a great portion of the power being lost, as now, the revolutions of the paddle will continue with as good effect as in calm weather. Should any circumstances render it necessary to remove the steam power, the wheel may be immediately unshipped, or its action upon the water may be prevented, and sailing power may then be applied. The vessel has been built at the yard of Mr. Wynn, under the direction of Mr. Smith, and is of exceedingly elegant construction Its dimensions are as follow:—Extreme length fore and aft, 125 feet; length between perpendiculars, 107 feet; breadth of beam, 22 feet 6 inches; depth of hold, 13 feet; diameter of screw, 7 feet; length of screw, 8 feet; and it is intended to apply engines of 45-horse power.—*Evening paper.*

Steam Navigation.—A few days since the Rainbow, a new iron steam ship, belonging to the General Steam Navigation Company, on her way to Antwerp with the tide, performed the distance from the Brunswick Wharf, Blackwall, to Gravesend, a distance of twenty miles, in one hour and four minutes. We believe this is the quickest passage on record. The Rainbow has become an object of great curiosity from the extraordinary speed she has displayed, and as proving beyond a doubt the safety and durability of iron-built vessels at sea.—*Morning Post.*

The Gorgon Steamer.—The Gorgon steamer arrived at Passages, in 54 hours, from Plymouth Sound, having left that port on the 15th, steaming all the way against a strong head wind. We have heard of no set trial with the Phœnix, but she performed the distance from Passages to Santander on the same day as that vessel, having left the former place, with 600 troops, four hours and a half after her, and when she arrived at Santander found the Phœnix had only anchored half an hour before her, thus gaining four hours in a run of 80 miles, going nine knots and a half against a heavy head sea. Lord J. Hay, and all the officers on the station, have expressed themselves in high terms of the superior qualities of this powerful and magnificent vessel. The report of the efficiency of the engines is so favourable, that the Lords of the Admiralty have been pleased to order Messrs. Seaward to supply a set of similar ones for the Cyclops, now building at Pembroke. Letters from Passages state that the Gorgon steamer, on her way out from that port, caught fire twice somewhere in her paddle boxes, owing to friction.—*Devonport Telegraph.*

At a public meeting held at Sunderland, the mayor in the chair, resolutions were passed and a memorial to the crown adopted, praying that steps should be taken by government to appoint fit and proper persons to examine the machinery and boilers of all steam vessels, with power to interdict their departure where the safety of the public might be endangered.—*Sunderland Beacon.*

Launch of a new Steam Ship at Belfast.—At the beginning of last month, a beautiful vessel, the Aurora, was launched from the ship-building yard of Messrs. C. Connell and Sons, at Belfast. She is decidedly a most superior steam vessel; her model—whether we regard the beauty of the lines from the paddle-boxes forward to the stem, or the gentle curvature of the quarter from the bends to the gunwale, now so much admired in some of the best Clyde-built steamers—is unexceptionable, and has been so pronounced by first-rate judges; while it is evident that speed, combined with large tonnage, on a light draught of water, has been completely attained in her build. It ought to be a source of pride to the enterprize of Belfast, that the Aurora will be wholly of Irish manufacture. Her dimensions are as follow:—Length of deck, from head to stern, 170 feet; breadth betwixt paddle-boxes, 23 feet; actual admeasurement, 453 tons; estimated burden, 750 tons. She will be propelled by engines of 240 horses' power.—*Belfast Whig.*

PUBLIC MEETING OF THE GREAT WESTERN RAILWAY COMPANY.

A crowded meeting was held at the Merchants' Hall, Bristol, Wednesday, Oct. 10, in pursuance of a resolution come to at the half-yearly public meeting, that the adoption of the report should be deferred until the second week in October, it being printed and circulated in the mean time.—Mr. W. U. Sims having been called to the chair, said,—Gentlemen, the circumstances which have caused our meeting this day, must be fresh in your recollections, that the consideration of the report of the directors was deferred at the last meeting, on account of its embracing so many important matters. The directors did not oppose the resolution, and the proper period is now arrived for the meeting to discuss and decide upon its reception. Some decision must be come to this day, for it will be unjust both to the directors and the proprietors to any longer delay it. Such a decision will not, however, commit the company as to any future measures. The directors have abstained from laying before the meeting any official report, being of opinion that such a course will only give rise to discussion, and divert attention from the business of the day I wish, however, to give some explanation upon two or three material points First, the traffic has realized every hope which could have been formed, the receipts for the last 18 weeks amounting to 29,694*l.* 5s. 11d., being an average income of 1094*l.* 16s. per week. The receipts for the month of June were 6,459*l.* 16s.; for July 6,918*l.* 2s. 5d.; for August, 7,154*l.* 10s. 11d.; and for September, 7,599*l.* 19s. 1d. Now with regard to the expenses incidental to the traffic, a full and accurate account has been taken, and it is found that 10,925*l.* 12s. 1d. has covered all the expenditure, with the exception of that which has been required for repacking that portion of the permanent way which was found to be needful. Instead of an expenditure of 300*l.* a-day, with a receipt of only 200*l.*, as was somewhat ingeniously stated, the expenses have been less proportionately than that of other lines. As respects the cost of laying the rails on timber, the directors have found that with a heavier rail of 60lb. to the yard, and a larger scantling of timber without piles, that the cost will not exceed 7,000*l.* per mile, and in truth responsible parties have offered to undertake it for that sum from Maidenhead to Twyford. The contract at Reading, which has been taken from Mr. Ranger, has been let to three sub-contractors, who have engaged to finish it in seven weeks. The meeting will recollect the circumstances under which it was judged necessary to have report from Mr. Nicholas Wood, on the line to Maidenhead; from whom a letter has been received, in which he states that it is his intention to undertake a course of inquiry, and make experiments not only upon the Great Western, but upon other lines, which at present have not been sufficiently extensive to justify him in forming that sound and practical conclusion at which he is desirous of arriving. Subsequent to the last meeting, and in consequence of a suggestion from a shareholder, a reference has been made to Mr. Hawkshaw, the engineer of the Bolton and Bury Railway, and that gentleman has returned a report, which, however, the directors do not consider it fair to lay before the meeting till Mr. Wood has also submitted his report. The directors have, however, no wish to conceal Mr. Hawkshaw's views, which are extremely comprehensive; but his recommendations the directors consider will be prejudicial to the undertaking if adopted. Mr. Hawkshaw recommends a total change of plan—that they should begin *de novo*, take up the rails, and lay them down at the 4 feet 8½ inch gauge. The directors have, however, thought it proper that the report of Mr. Wood should be received before either are submitted, and for that purpose a special meeting of the proprietors will be called to take both those reports into their consideration. After a discussion as to Mr. Hawkshaw's report a proprietor inquired when it would be probable that Mr. Wood's report would be ready? The chairman replied, that Mr. Wood had stated that it would take him three weeks more to finish his experiments on the Great Western line, and probably some two or three weeks more for his comparative experiments on other lines. It might be six weeks before his report would be received, and there would be no objection to print and circulate the reports amongst the shareholders a week or ten days previous to the meeting. After some discussion the chairman said, that for questions to be asked of Mr. Brunel, that gentleman was on the spot and would answer them at once. Mr. Brunel said, that with regard to the engineering expenses, the salaries of himself and his assistants were not so large as those on other lines, and the amount was swelled by the introduction of a number of items which had no connexion with that department. The next observation was on an important point. Mr. Heyworth had drawn a conclusion that he (Mr. Brunel) had a tendency to incur expense *coute qui coute*. Now he held it to be quite as essential for an engineer to show he could build cheap as build well. Mr. Heyworth had read a passage from his report relative to maintaining the width of tunnels. He certainly thought it would be better in a line of 120 miles, where a breadth of 30 feet was kept up throughout, and where there were not above two or three miles of tunnelling, that the same breadth should be preserved in the tunnels, which if once constructed could never be altered, except at an enormous expense. That was his reason, and not for the mere whim of making a tunnel on a larger scale than other railways, and it ought not to be assumed that he had run wilfully and wantonly into expense for the sake of a grand work. Mr. Brunel then proceeded to remark on the question of gradients, and demonstrated that the plan adopted on the Great Western involved a saving of locomotive power to the extent of 26 per cent., and concluded by stating, that he felt convinced that experience would show that the very point which had been urged against him as extravagant would prove to be both economical and profitable. Mr. Heyworth explained that the 26 per cent. alluded to by Mr. Brunel, was applicable only to the power of the engines. He perfectly agreed also with Mr. Brunel, that the object sought to be obtained was a profitable outlay. Professor Babbage entered into a long account of his observations and experiments on different railways. He had conversed with scientific men concerned with twelve railways—he had travelled on seven; and the result of his experience was, that in those seven the Great Western stood as No. 2 for comfort and ease in travelling. From his knowledge of Mr. Nicholas Wood, he doubted not that ample justice would be done; but he ought not to be hurried. Discussions like the present were calculated to do more harm than good, by their tendency to dishearten their engineer, and paralyse the energies of the directors. If the meeting should express a want of confidence in the directors, and resolve upon undoing what had been done, it would retard the progress of railways generally, and be a serious injury to science. Considerable discussion of a friendly nature then took place, Mr. Heyworth stating that he would withdraw his motion for adjourning the present meeting, if the chairman would undertake, that as soon as Mr. Wood had presented his report, and Mr. Brunel had had time to examine it, a special meeting should be called, which was acquiesced in, when it was finally resolved that it should take place in London, on the 20th of December.

PROGRESS OF RAILWAYS.

Edinburgh and Glasgow Railway.—Messrs. Gibb and Son, of Aberdeen, so well known for the execution of the Dean Bridge, the Glasgow Bridge, and other extensive works throughout the country, are the successful competitors for the first and greatest contract on the line of this railway, viz., that from Norton to near Priestinch, being a distance of about five miles. This contract comprehends the great viaduct across the Almond valley. It is the heaviest part of the line, and will require the longest time in the execution. It has been contracted for, on the whole, within Mr. Miller's Parliamentary estimate; and when we look to the names of the respectable contractors, we cannot help thinking that the settlement of this contract on such terms is a matter of the utmost importance, and that it will tend materially to insure the most successful results to this great national undertaking.—*Glasgow Courier.*

The Birmingham, the Southampton, and the Great Western Railway—for all of which one common terminus might have sufficed, and which might, by an early, judicious, and cordial combination of interests, have obtained a common terminus as near as any to the metropolis—have, partly through mischance, and partly through mismanagement, been obliged to have separate termini at distances of 2½, 3, and 4½ miles. The inconvenience thus entailed upon the public is incalculable, yet it is an inconvenience which must now be regarded as remediless. A junction of the three lines, or of any two of them, is, of course, no longer to be thought of; and the apprehension that, were one of them permitted to come any further into town, the proprietors of the others would insist on being equally favoured, will effectually prevent all three from being ever extended much, if at all, beyond their present limits.—*Railway Times.* We do not entirely agree with our contemporary, "that a junction of the three lines is no longer thought of." Such a junction and extension of the three great metropolitan lines must sooner or later be made. After the Liverpool and Manchester Railway was finished, it was very soon found out, by the shrewd merchants and manufacturers of those towns, the great inconvenience of having the termini so far distant from the places of business, particularly the Liverpool terminus, which was extended subsequently at an enormous cost. The same inconvenience, when the metropolitan railways are in full operation, will be experienced; and, unless they do unite, neither one nor the other will be able to approach nearer the city; as the cost of a metropolitan line will be too great for any *one railway singly.* If it had not been for the untoward opposition of the Southampton Railway Company, their line, and also the Birmingham and Great Western, might have been extended to the banks of the river Thames, and within *half a mile of the Royal Exchange and Charing Cross;* but the unaccountable jealousy of the Southampton Railway Company, because the line in question was to have crossed the river Thames and united their line with the *Great Western* and the Birmingham Railway, and offered to the two last the same excellent terminus, caused them to lose the traffic of the Brighton line on six miles of their railway, and all the city traffic of the Great Western and Birmingham Railways, and likewise the enormous traffic of the Richmond branch on two miles, besides *thousands* of passengers to the different towns and villages in the vicinity of the metropolis;* we have not the least doubt that the opposition of the Southampton Railway Company to the line in question costs them *ten thousand pounds per annum* in loss of traffic. We still hope that the line to unite the three railways will be made. The cost of carrying it into Parliament would be trifling, as all the plans and data are in the possession of the projector.

London and Brighton.—The Brighton railway interferes with the Merstham tramway, and the Railway Company are bound, under their act, to purchase the whole of the tramway from Croyden to Merstham at a price to be fixed by arbitrators mutually chosen. The arbitrators have made their award, and the Railway Company are now in possession of the tramway. The claim made by the Tramway Company was no less than 42,000*l.*, and they employed counsel to substantiate their claim, but the arbitrators awarded only 9,614*l.*

Dundee and Arbroath Railway.—The greatest interest was excited at Dundee on Saturday, 6th ultimo, in the ceremony of opening this railway. At a quarter past eleven, six omnibuses departed for the station at Craigie. Twelve o'clock was the time appointed for the departure of the train; and a little before this hour the scene was exceedingly animated and enlivening. There were ten carriages,—five first and five second class carriages,—filled with passengers, amounting to between 300 and 400. The carriages were built in Dundee, by Cuthburt and Son, and in Perth by Wallace, and do great credit to the builders. *The first class carriages* are fitted up in the most comfortable and elegant style, with plate-glass windows and sides, and cannot be surpassed by any description of carriages. *The second class carriages* are also exceedingly comfortable, and are supplied with air cushions, and in every respect as easy as the first class, only they are open at the sides. *The engine* named the "Wallace" was built in Dundee, by Kinmond, Hutton, and Steele, and is without exception one of the most splendid and beautifully finished pieces of mechanism; indeed, all present who had seen the Scorpion, Spitfire, and other celebrated English engines, gave the preference to the Wallace. It has been constructed on the most simple principle; and the taste and style of finish is unequalled. It is placed upon six wheels, the centre or driving wheel being 5½ feet diameter; the other wheels are of less dimensions: the cylinders are placed in a horizontal position; the stroke 18 inches long; the diameter of the cylinder is 13 inches. This engine differs from most of the English locomotive engines, inasmuch as the crank is placed on the outside of the wheels, which adds much to the simplicity, as well as to the efficiency and safety of the machine. *The ceremony* was the opening of a mean of communication which brings Arbroath to the immediate neighbourhood of Dundee, and enables it to participate in the rising and profitable trade of this seaport. The trip was performed in about 40 minutes, but speed was not the object of the directors; and Mr. Miller, of Messrs. Grainger and Miller, of Edinburgh, the engineer of the company, and under whose guidance the engine and train was placed, wisely preferred safety to the chance of any accident, which might without any fault have occurred, where everything was new and imperfectly tried and tested. The train returned from Arbroath to the Craigie station in 40 minutes, exclusive of a stoppage of five minutes. *The length of the railway,* which has been executed, is 15 miles, and it is admitted on all hands to be the finest line for the extent in Britain. The steady motion of the carriages and engine may partly be ascribed to *the gauge* which has been adopted upon this railway, which is 9½ inches wider than the principal English railways, but 18 inches narrower than the Great Western Railway.

North Midland.—The works on the line near Chesterfield are rapidly progressing. The last hill, near Tapton-house, in the contract of Messrs. Leather and Waring, is commenced excavating; and there is every probability of its being finished in June next, when it is expected that the whole of their contract, nearly four miles, will be ready for the permanent rails being laid. It is supposed that the whole line will be opened in January, 1840.

* We should like to see the returns of the company for passengers conveyed to Wandsworth, Wimbledon, and Kingston; we doubt if it would show a tithe or even half that number, of what might have been conveyed had their line been extended to the city.

Grand Caledonian and West Cumberland Railway.—Mr. Locke has abandoned his central line through Shap Fell, and given up all opposition to the Morecambe Bay line. Mr. Locke states:—"There is no question as to the route it ought to take. The London and Birmingham, the Grand Junction, and the North Union, line may be considered as already made (in two months they will be opened throughout). They form one grand line from London to Preston, pointing upon Carlisle; thus one half of the line from London to Glasgow is accomplished. The population of Lancashire, its position, and connexion with the trading districts of Scotland, place the eligibility of this route above all others pre-eminent. The population of the whole district from London, along the eastern side of the Island, to York and Newcastle-upon-Tyne, when compared with that of Cheshire, Staffordshire, and Lancashire, is insignificant; and to such towns as Liverpool, Manchester, Warrington, Stockport, Macclesfield, Ashton, Oldham, Rochdale, Bolton, Bury, Blackburn, Wigan, and Preston, a communication with Scotland must be of immense importance; and whilst all this can be accomplished, and still preserve the most direct and shortest route from London to Glasgow, there can be no plea against such a communication being made through Lancashire."—*Lancaster Guardian.* Mr. Hague has also finished his special survey of Morecambe Bay.—Measures are in progress to bring forward this great national undertaking, and a meeting of the subscribers will shortly be held to receive Mr. Hague's report, and consider as to future measures. We understand that the proposed line crossing Morecambe Bay was projected by Mr. Hyde Clarke. The boldness of the proposal, when first made, was laughed at by all the county; we see, by the above extract, how time and perseverance may overcome prejudice and ignorance.

Great Western Railway.—We understand that the contract for executing the line between Ruscomb and Reading, which was forfeited by Mr. Ranger, to the great obstruction of the company's plans, is now subdivided into four portions, and re-let to contractors, who are bound to complete the line within seven months. Should they succeed in their undertaking, the whole distance between London and Reading will be opened for traffic in the course of the next summer. Between Bath and Bristol, and on the eastern side of Bath, increased activity is manifested by the various contractors. We learn that a very large body of men, recently discharged in consequence of the completion of the London and Birmingham Railway, have been set to work at various points of the Great Western Railway. The principal engineer is strict in enforcing penalties for the non-completion of a due quantity of work within the time specified, and everything indicates much determination and energy in the direction. Still the operations are on such a gigantic scale, and the obstructions of tunnel work so formidable, that we do not look for the perfect completion of the line for a very long time.—*Berkshire Chronicle.*

Leeds and Manchester Railway.—The report of the directors read at their half-yearly meeting, states that the road to Littleborough, through Rochdale, will be opened in May next, and the whole line is expected to be completed in the year 1840.

Northern and Eastern.—A most important negotiation between the Northern and Eastern Railway Company and the directors of the Eastern Counties has been brought to a conclusion, by which it is agreed that the two lines shall have one common terminus at Shoreditch, the land for which is already in possession of the Eastern Counties line, while the works which connect it with Bow and Stratford are in rapid progress, as may be seen by any one who crosses the valley of the Lea.—*Hertford paper.* We understand that the terms of the bargain between the Northern and Eastern and Eastern Railway Companies are, that the former are to pay 7,000l. a year for the use in common of the Eastern Counties' London Station, and 4d. per passenger. A good bargain, if the passenger traffic on the Northern and Eastern Railway prove to be, as anticipated, nearly as good as the traffic of the Eastern line itself. The toll which the Croydon Railway Company are to pay the Greenwich is, we believe, the same, namely, 4d. per passenger, but they are to provide their own station.—*Railway Times.*

The North Union Railway was opened on the 21st ult., from end to end. This line connects Preston with the Grand Junction. The entire line, from Parkside to Preston, measures 22 miles and a half; the first two miles and a quarter are up a slight incline and curve; next come four miles of dead level, and perfectly straight. A steep incline, rising at the rate of one in a hundred, brings the traveller to the town of Wigan, the company's first station on the line. Here a splendid station-house has been erected, alike well adapted for the transaction of the company's business and general public accommodation. The line is carried, by means of an iron bridge, supported by massive pillars of the Doric order, across the turnpike-road leading into Wigan. This commences the Douglas contract, undertaken by Messrs. Mullens and M'Mayor, which extends five miles along the line to Coppull, through some exceedingly heavy embankments and cuttings, in some places full 60 feet deep. In this distance there are two inclined planes, the highest rising in the ratio of 1 in 100. Coppull forms the summit, and here commences the Yarrow contract, which is carried across one of the most beautiful valleys in England. From Coppull to Yarrow there are inclined planes, two short ones, and the third extending to more than a mile in length, and formed by embankments raised in places more than 60 feet above the the natural level. The chief alteration in this line is the wooden bridge across the river Yarrow. It will be recollected by those conversant with railroad affairs, that a culvert of considerable extent had been formed across the river, and the embankment placed upon it. The flood of last November caused the river to overflow so considerably as to blow up the arches, and to carry away the embankment to a very considerable extent. The loss to the contractor was estimated at nearly 6,000*l.* In the place of this culvert and embankment a bridge, made of framework, has been erected. It is 73 feet above the bed of the river, 400 feet long, and 82 feet wide, and in its construction more than 30,000 feet of timber was used. There are two more inclines between the Yarrow-bridge and Preston, one at Leyland, the other at Farrington; and immediately previous to reaching Preston there is a deep excavation, 41 feet, cutting. At this place the engine was stopped, and the directors there terminated their trip. The distance from end to end was performed in 45 minutes. The directors in their trip were preceded by the No. 5 engine, built by Messrs. Hicks, of Bolton, which, with Messrs. Jones and Co.'s engine, worked admirably.—*Times.*

Glasgow, Paisley, and Greenock Railway.—The directors, we are happy to learn are pushing on their works with spirit, and, since we last noticed their proceedings, have let two more portions, viz. :—the Greenock and Cartsburn Hill contracts; the former to Messrs. Allison and Brodie, and the latter to Mr. Barron, of Glasgow. Both are to be completed next year. The Finlayston contract is already advertised; and this, with the short length from the river Gryfe to Paisley, which is immediately to follow, and for which the plans are ready, will complete the line to Glasgow.

Irish Railways.—Meeting at Ballinasloe.—The meeting of the gentry and landholders of the province of Connaught, on the subject of the report of the railway commissioners, was held on Saturday. Mr. Bodkin, M.P., presided. The requisition for this meeting was signed by the Marquis of Sligo, the Earl of Lucan, several members of Parliament, and thirty-six deputy-lieutenants and magistrates of counties. The object was to protest against the line of railway recommended by the commissioners. The following resolution was amongst those adopted:—"We are of opinion that the construction of railways in Ireland should, as in other parts of the empire, be left to private enterprise, aided, assisted, and controlled by government, as Parliament should decide upon, according to the usual and accustomed rules, founded upon evidence, with due regard to public interests and private rights." A vote of thanks was passed to the *Times* and several other journals, English and Irish, which had "advocated the claims of Ireland to railway communication, in opposition to the conclusions of the commissioners."

Hull and Selby Railway.—It is now some time since we made any allusion to the progress of this undertaking, and we therefore now lay before our readers such information with reference to it as has come within our knowledge. A considerable number of men are employed upon the various contracts, and the contractors are exerting themselves to complete as much of the work as possible previous to the winter; about 150 yards in length of the embankment at the west end of the Foreshore, near Hull, are completed, and 100 yards more raised to the full height; a great part of the stone facing is also finished. The trench at the foot, for a further distance, is also excavated, and part of the embankment thrown up; a considerable quantity of stone and chalk has been delivered for this work. The embankment at the east end of the Foreshore, near Mr. English's wharf, is in progress. On the Hessle contract, the embankment from Dairycoates to Hessle Harbour is nearly finished and ready for ballasting, and the various culverts wholly or nearly completed. The cuttings westward, at Hessle and Ferriby, are proceeding favourably, although the wetness of the season prevented the great progress which would have been made under more favourable circumstances. The Brough contract has been commenced, and when all the corn is cleared off the ground, the works will proceed more rapidly. The Market Weighton embankment requires only 6,000 cubic yards of earth to finish it, and the foundations of the bridge over the canal are ready to receive the ironwork, which is all prepared, and daily expected from the foundry at Derby. On the Howdon contract (a length of nine miles), only a small part of the formation of the railway at each end remains unfinished, and this is in progress; near 4,000 tons of chalk have been landed, and partly broken for ballasting; several culverts are finished, and the bridge over the railway at Eastrington is commenced: a considerable quantity of bricks have been made for the use of these works. The foundation of the bridge over the river Derwent, on the west side, is nearly ready for the piling, and the coffer-dam on the east side finished. The cutting west of this river is progressing, and the earth is carted to form the embankment. The other works of the Selby contract will proceed as the land is cleared of corn. The sills upon the pier-piling of the Selby bridge are fixed as opportunities are presented at low water, and in a few weeks it is expected the whole will be completed so as to allow the founders to put up the cast-iron standards, which are all ready for fixing. The Manchester and Leeds Railway Company design to open their line in 1840; this is also expected to be the case with the York and North Midland, and other lines with which that from Hull to Selby will be connected; and we may, therefore, anticipate the arrival of the period when the journey from Hull to London will be accomplished by railways in little more than half the time it now occupies. The advantages to be derived from railway communications cannot yet be fully estimated.—*Hull Times.*

Midland Counties Railway.—There has been an interruption this week to the making of the embankment on the left of the Humberstone-road, owing to the bridge across the turnpike not having been so far completed as to permit the gang waggons to pass over it. From this cause many excavators and other people have been unemployed, but it is expected that they will resume their work next week. It seems that the fixing of the iron "ribs," or arches, across the road, is found a difficult task, and occupies much time. One-half of the new bridge on the London-road being now in a state to pass over, the other portion of the road is about to be broken up in order to complete it.—*Lincoln Gazette.* The following is the amount of earth work executed, and the number of men, horses, and locomotive engines employed, on the works of the Midland Counties Railway Company, from the 27th of August to the 22nd of Sept.: earth work, 203,037 cubic yards; number of men, 4,373; number of horses, 438; locomotive engine, 1.

North of England.—There having been various reports that the North of England Railway Company did not contemplate the extending of their branch to York, we have authority to contradict all such reports. The fact is, that the extension to York is positively determined upon; land has been purchased, proper arrangements have been made, and a memorial has even been sent to the corporation of York, soliciting their assistance in forwarding this great public undertaking. The branch will terminate on the west side of Thief-lane, directly opposite the House of Correction.—*York Herald.*

Birmingham and Gloucester Railway.—The men employed on this railway on the line between Moseley and Camphill, are now prosecuting their labours both night and day, when the weather permits. The second arch, which connects the land severed by the railway at Balsall Heath, is now in course of erection.—*Birmingham Advertiser.*

Preston and Wyre Railway.—The works of this interesting line are in a very forward state; and being a continuation of the grand chain of railways to the north, the town of Fleetwood, on the coast of Lancashire, will be accessible by railway travelling in ten hours, as a fashionable watering-place for the inhabitants of this great metropolis.

The construction of the proposed new road from Amesbury to Kennet, if carried into effect, will confer a great public benefit on the county of Wilts, and will be the nearest connecting link betwixt the Great Western and the Southampton and Salisbury Railways.—*Railway Times.*

Manchester and Stockport Railway.—The Stockport length of the Manchester and Birmingham Railway has been commenced by the contractor, Mr. John Brogdon, of Manchester, in good earnest, nearly half a mile of ground from Blacbrook to this town having already been broken. About 150 men are engaged in the cutting; and already has one of the main depths of 22 feet been obtained and cleared out a considerable distance, in which temporary rails are being placed for the purpose of carrying the superfluous soil away towards Manchester, where great quantities will be required to fill up the declivities. Mr. Brogdon's intention is, we believe, if possible, to complete his contract between the Hyde-road and this town within eighteen months, although the time for the completion of the work is limited to twenty months. The immense viaduct over Heaton-land and the river Mersey is to be proceeded with immediately; and the line to the point of junction with the Grand Junction Railway, at Chebsey, near Stone, is to be now pushed forward as quickly as possible.—*Stockport Advertiser.*

South-Eastern Railway.—Last week the chairman of the board of directors, accompanied by Mr. Cubitt, engineer, and Mr. Fector, M.P. for Maidstone, a director, inspected the works now in progress in this immediate neighbourhood (Canterbury). Great satisfaction was expressed at the advance made since the last visit of the directors; and the facilities anticipated in working through the chalk have been realized to an extent far beyond that of the most sanguine of its promoters. The line between this place and Folkstone has now been finally determined upon; and in the course of a fortnight the plans and specifications for contracts throughout to Folkstone will be ready for inspection by parties desirous of contracting for the same. From Folkstone upwards there is only one work of importance on the line—viz., at Beachborough. Beyond this point, the whole line to its junction with the Brighton Railway in the county of Surrey presents no works of a serious character. The central district from Ashford to the westward is, we believe, quite unparalleled in the facilities which it offers in its construction. For a length of 45 miles, from Ashford to its junction with the Brighton Railway, the line is perfectly straight, with scarcely any cutting, and so nearly approximating a level as to afford scope for the attainment of the highest velocities of which the locomotive engine is capable. The works will be executed at an expense very far short of the average of railways, and, from the contracts which have already been let, we have every reason to believe that the Parliamentary estimates will be more than sufficient to meet the expenses of their construction.—*Kent Herald.* The contract for the line of railroad from Tonbridge to Tudely has been taken by Mr. Charles Dutton, who has executed several heavy contracts under Mr. Cubitt.—*Cinque Ports Chronicle.*

Carlisle and Maryport Railway.—It is intended to open the first nine miles of this line, from Aspatria to Maryport, on the 18th of June, 1839.—*Carlisle Patriot.*

North Union.—The works of this railway every day continue to advance, step by step, towards their completion. On Tuesday the last keystone was inserted in the last arch of the Ribble viaduct, and two engines are daily plying between this town and Leyland, for the conveyance of ballast, and the removal of earth for the slopes or embankments. Should the weather continue favourable, no doubt appears to be entertained but that the entire line will be opened towards the middle of next month.—*Preston Chronicle.*

The Railway Bridge over the Tyne at Blaydon is now completed, connecting the branch that runs north of the Tyne into Newcastle, with the main line of the Newcastle and Carlisle Railway. This branch is so far advanced, that, in a short time, trains will enter the town by this route, instead of proceeding to the Redheugе station.—*Dumfries Times.*

Brighton and Dieppe Railroads.—We are happy to find that the works of these two railroads, in both of which Brighton is most materially interested, are being carried on with great activity. It is said even that the Dieppe line will be first completed, and that great improvements will be made in the harbour of that town for the accommodation of steam boats and other vessels. At Merstham in Surrey there are a great number of men employed—upwards of five hundred—and the line from London to that place is in such a state of forwardness that tenders have been made to coach the remainder of the road to Brighton. Temporary trams have been laid along the branch line to Shoreham, upon which the carts for the removal of the earth will shortly run; and we shall not be surprised if by the next summer this portion of the line is opened for the conveyance of passengers and goods. The formation of the railroad through the centre of Sussex must be attended with the most decided advantages to Brighton; but, taken in connection with that of Dieppe,—by which the metropolis of England and that of France will be brought within a few hours of each other—*Brighton Herald.* Two thousand six hundred workmen are now fully employed on the Brighton railroad, and the works are carried on with great spirit. The branch to Shoreham has been partially carried forward, as far as Portslade, and the carts on the trams are engaged in removing the earth on the higher grounds to fill up the valleys. Several culverts and bridges are completed. The work is done in the best and most substantial manner.—*Hampshire Telegraph.*

Sheffield, Ashton-under-Lyne, and Manchester Railway.—Several contracts with landowners have already been completed upon the most favourable terms, and that the directors are in treaty with other parties, with every prospect of a similar result. The engineer has also received instructions to proceed immediately with the driftway through the summit ridge, and other works connected with the tunnel.

The Shoreham Railway.—The works are carried forward with activity. The men are labouring most industriously at the cuttings leading to the spot opposite the mill, where the tunnel will commence. The shafts appear to be in order for working, and the tunnel was commenced, it was understood, on Saturday last. A considerable excavation has been made on the Hove-road, leading to Blachington, in which a very handsome and substantial bridge, with an elliptical arch, has been constructed. The ground here is on the level of the railroad, which has rendered this excavation necessary in order to carry it over the public road.—*Brighton Herald.*

Great North of England Railway.—It is expected that this line will be ready for traffic in the spring of 1840, simultaneously with the York and North Midland, the North Midland, and the Midland Counties' Railways—thus at once giving the public in the north a direct railway communication with the metropolis. We hope to be able to give some further particulars of the line next week.

Glasgow, Paisley, and Ayr Railway.—Since the fields have been cleared, a large number of additional hands have been employed on this railway, and the operations to the westward of Arkleston Tunnel, as well as to the eastward of it, are proceeding with much activity.

Railway from Manchester to the Humber.—We learn that a survey of the proposed line from the Sheffield and Manchester Railway, near Penistone, to the Humber, is now proceeding under the superintendence of Mr. Locke.—*Sheffield Iris.*

Accident on the Liverpool and Manchester Railway.—On Thursday evening last, between the hours of 8 and 9, as a heavily laden luggage train was proceeding from Liverpool towards Manchester, the engine was thrown off the line at the Newton junction, in consequence of the man whose duty it was to shift the rails after the Birmingham train had passed neglecting to do so. The result of this carelessness was calamitous in the extreme, a poor fellow named Hannon being killed on the spot, and the "breakman" so dreadfully injured that his life is despaired of. The escape of the engineer and fireman was miraculous. Hannon was riding in a carriage with a number of pigs intrusted to his care, 30 or 40 of them also being killed.

Accident on the Great Western Railway.—Much excitement was on Friday, the 26th ult., created throughout the metropolis by a report that a dreadful accident had occurred on the Great Western Railway, which had proved fatal to Dr. Dionysius Lardner. The report is unfounded as respects the Doctor, but we are sorry to add, that an accident attended with fatal consequences has occurred on this line, and that the unfortunate gentleman whose life has been sacrificed is Mr. Field, connected, it is said, with Dr. Lardner as pupil or assistant. The circumstances connected with the lamentable occurrence have been kept very private, the greatest secrecy having been enjoined on all the servants of the company; but from inquiries instituted by our informant in the vicinity of the railway yesterday, the following particulars have been obtained:—For some time a series of experiments have been in progress on the line between London and Maidenhead, for the purpose of trying the powers of the engines and the stability of the rails and permanent ways. On Thursday last the "Eureka" engine started from the terminus at Paddington, with an experimental train, consisting of several carriages and trucks, heavily laden with iron and stone. On the tender of the engine were Mr. G. Clark, Mr. Dickson, and Mr. Clarkson. The party reached Maidenhead without any accident, and left about 4 p.m. on their return. During the afternoon Dr. Lardner and Mr. Field, being engaged in proving the rails near the London terminus, were on the approach of the "Eureka" on the eastern side of the intended station at Acton, near to Wormwood Scrubs. Mr. Field was at the moment stooping down, more narrowly to watch the effect of the approaching train upon the rails, but, miscalculating its distance, or suddenly losing his presence of mind, he was unable to recover himself before the train arrived, and the wheels of the engines passed over his body. The train was almost instantly stopped, and the unfortunate gentleman was found in a dreadfully mutilated condition. Life was not however extinct, but after breathing for two or three minutes he expired. His remains were conveyed to Paddington, and deposited in one of the offices of the company, to await the coroner's inquest.—*Times.*

FOREIGN RAILWAYS.

The Versailles and St. Cloud Railway.—The keystone of the vault of the tunnel at St. Cloud, was laid by Messrs. Lanjuinais and Emile Pereire, the administrator and director of the Company. The first stone of the tunnel, which is more than 1,500 feet in length, was laid on the 26th of March. Some masonry work is all that now remains to be terminated. The removal of the earth is going on with great activity, and will be finished in a month. All the vehicles and other *materiel* have been directed upon Versailles; but as there remains but little work upon the line, several brigades of workmen have been discharged, amounting for the last month to upwards of 1,500 men.

Railway from Florence to Leghorn.—The committee of the company who have proposed to undertake the construction of the railway, consider it their duty to inform the shareholders, that on the 6th of August last they concluded in London a contract with Robert Stephenson, Esq., one of the most celebrated men England boasts of for large undertakings of this character. By this contract, Mr. Stephenson binds himself to prepare a statement of the estimated expenditure of the proposed railway, and to transmit the same on or before 31st May next. For this object, two of his principal assistants have already arrived, viz., Mr. William Hoppner and Mr. Richard Townshend, who immediately commenced operations, and the Imperial and Royal Government have been pleased to recommend these gentlemen to all the government and local judicial authorities, to obtain from them every assistance and protection in their operations.—*Gazzetta di Firenze.*

The *Journal de St. Petersburg* states that the number of passengers on the railroad between St. Petersburg and Zarskojeselo during August last was 73,191; and between Zarskojeselo and Paulovsko, 26,088; making together 99,279 The receipts amounted to 126,504 roubles. Since April last, the total receipts have amounted to 514,541 roubles, and the number of passengers between St. Petersburg and Zarskojeselo to 287,643.

French Railways.—A panic has seized the holders of shares in these undertakings which are all below par, except the Versailles (right bank) and the St. Germain. The Paris press is much occupied with these circumstances, and display a great deal of, what we should consider, infantine reasoning on the subject.

Austria.—The second section of the Great Northern Railway, named after the Emperor Ferdinand, has been opened. This division runs from Deutsch Wagram to Unter Ganserndorff.

Haarlem Railway.—The works on the railway between Amsterdam and Haarlem proceed rapidly, and it seems that the opening of it may be confidently expected to take place in the spring of 1839.

Brussels Railroad.—The concourse of passengers at the station of the Brussels railroad increases daily. On Saturday last there were above 80 carriages drawn by two engines at half-past eleven o'clock. Of the 600 or 700 passengers a company of the 3rd regiment of the line formed a part.

Austrian and Russian Railway.—A company of capitalists at Brody, in Galicia, have made proposals to the Austrian and Russian Governments for forming railroads from Brody through Lemberg to Vienna, and from Brody by Berdytscheff to Odessa, on condition of enjoying the exclusive privilege of the road for 100 years, after which period the roads are to be given up to the respective Governments of the two countries. The proposal is said to have been received with so much favour at Vienna, that agents of the company have already entered into negotiations with the proprietors of lands through which the Austrian road is to pass; and the Emperor of Russia is stated to be still more inclined to listen to the application, and he is anxious to multiply these roads within his dominions, and in this case is not required to make any advance of money. The moneyed houses of Vienna are said to be well disposed to the undertaking.—*French paper.*

The railway and steam navigation conveyance between Paris and London, or Paris and Portsmouth and Southampton, is now complete, attended with many comforts and scarcely any inconveniences. A party of English gentlemen left Paris by the new railroad last Thursday morning (Sept. 20) at 7 o'clock. They arrived at the steam-boat station on the Seine in less than one hour. They embarked about half-past 8, and landed at Rouen about 10 in the evening. Next morning at 6 o'clock they embarked on board a magnificent steamer, abounding with every luxury, and, after enjoying a most picturesque and varied voyage down the Seine, arrived at Havre soon after 12 o'clock, mid-day. They instantly shifted their quarters to the noble steam-vessel the Monarch, quite ready to sail. They reached Portsmouth and Southampton in the middle of the night, or soon after, and were in London in good time on Saturday, having reposed quietly in their hotels on Thursday and Friday nights.

ENGINEERING WORKS.

Proposed Harbour at Hastings.—A meeting of the committee appointed by the inhabitants of Hastings, to consider the practicability of constructing a harbour at that place for the trade of the town and steamers, at an expense not exceeding 60,000*l.*, was held on the 19th ult., to receive Mr. Cubitt's report on the plans of Lieut.-Col. Williams, R.E., and Mr. John Smith, which had been submitted to him. Mr. Cubitt's observations on the plan of Lieut.-Col. Williams were listened to with the deepest interest, and it was the subject of very general regret that he considered the sum of 60,000*l.*, to which the committee were limited, insufficient to complete the work in an efficient manner. Colonel Williams, however, said he should be prepared by the next meeting to show that his harbour could be made a good and efficient harbour for that sum. The difficulty which engineers have to contend with on this coast is the shifting shingle, the general course of which is from west to east, and which accumulates in immense masses on the west side of any piers or other works which obstruct its progress, and finally getting round them finds its way into the harbour, many of which on this coast become, as they are very aptly termed, "shingle traps." Another difficulty is presented by this obstruction, in the direction in which the mouth of the harbour should be made, if towards the south and south-west, the quarter most easy of access in gales from those points, it is expressly adapted to catch the shingle getting round the western pier, and if towards the south-east, whereby making the west pier overlap the eastern, it is thought this evil may be remedied, the harbour becomes more difficult to enter. Mr. Tait's ingenious plan for harbours of isolation, particularly noticed in our last number, seems calculated better than any other hitherto suggested to meet this difficulty; but as it has not yet been tried in practice, the inhabitants of Hastings would no doubt object to make the experiment of its merits, did not the increased expense present in itself a serious objection. The revenue for the harbour at Hastings, from the trade of the town and nighbourhood, would produce nearly 4,000*l.* a year on a scale of moderate tolls, and the proposed outlay of 60,000*l.* would be justified. The materials for building the piers are on the spot, the cliffs being composed of good sandstone, and a hard description of lime or Tilgate stone, very fit for the purpose. The tides rise on an average, at spring tides 22 feet, and at neaps 19 feet, circumstances very favourable for the undertaking; and the inhabitants are very sanguine that some plan may still be projected which will enable them to complete so very desirable a work for the sum placed at their disposal. Mr. Cubitt prepared a plan in 1837; it was however on too large a scale to suit the means of the town, the estimate being 150,000*l.*, and it does not appear to be his opinion that a sufficient harbour can be built under 100,000*l.*; it is singular, also, that being requested to advise the committee how they could lay out their 60,000*l.* in the most advantageous manner, he should now recommend an extension of his original plan, already too expensive, and thus tend to increase the difficulty he was solicited to remove, without showing how the expenses are to be met. A proposition was made at the committee meeting to call in the assistance of some other eminent engineer, but it was ultimately determined to print and circulate Mr. Cubitt's report, and the plans referred to him, and to meet on the 2nd November to reconsider them, and to hear Colonel Williams' explanation.

Irish Surveyors.—We find from the report on education in Ireland, that the Agricultural School, at Templemoyle, in its course of instruction, includes geography and map constructions, Euclid, trigonometry, and its application to heights and distances, land surveying, with use of theodolite, level, &c. The School has a good apparatus. Several of the pupils have been employed as ordnance surveyors, or by private gentlemen. The age of admission is about eighteen.

Harbour of St. Helier, Jersey.—The Committee of Piers and Harbours met for the purpose of taking into consideration the projected plans for enlarging the pier of St. Helier; and we have much pleasure in announcing that this committee approved unanimously of the plan drawn by Mr. Walker, and resolved upon recommending its adoption to the States.—*Jersey News.*

Deepening the Bed of the River Mersey.—It has been notified to the inventor of a plan for deepening the bed of the River Mersey (submitted to the mayor and corporation of Liverpool so far back as the month of May last), that, after his plan for deepening the bed of the river by means of a system of agitators had been several times submitted to the Dock Committee, they could not enter into negotiation with him on the subject of his invention, "as an apparatus for dredging the banks outside," which, it is said, has been proposed by their own marine surveyor, has been ordered to be tried. Mr. Tait's plan was certainly not to dredge, but to agitate, or harrow, or rake, the bed of the river, during ebb tide only; and we much apprehend that "to this they must come at last."

Bridge over the River Severn.—It is rumoured that a bridge will be built over the Severn at Newnham, and that the matter is to be taken up by Government. It is assumed that the mineral wealth lately brought to light in the Forest of Dean has tended much to the desire to improve the communications in this part of the country.—*Gloucester Journal.*

Woolwich Dockyard.—The whole of the concrete blocks have been removed out of the interior of the great dry dock, and at a cost, per contract tender, of 30,000*l.*, and it is now to be faced with real stone. This dock has already cost the country upwards of 70,000*l.*, and as yet not a ship or vessel of any description has been received within its gates or cassoon. In dimensions it is, perhaps, one of the finest in our ports.—*Standard.*

Southampton Docks.—In our second number we noticed the project of forming Commercial Docks at Southampton, and in a general way the advantages and peculiar eligibility of the site were pointed out. On Friday, October 12th, the first stone of the first dock was laid by Sir Lucius Curtis, Provincial Grand Master of the Free and Accepted Masons of Hampshire. In the evening the directors and their friends, with the Earl of Yarborough, Sir Lucius Curtis, &c., dined at the Star Inn, in honour of the occasion, when the usual toasts, embodying the hopes and promises of the undertaking, were proposed. The masterly speech of Richard Hathfield, Esq., grasps the subject so completely, and displays such a perfect insight into the secrets of commerce and its progressions generally, that we recommend it to the notice of our readers. We regret that we cannot find space for it in our journal. We understand it to be the intention of the spirited and enlightened directors to form the Docks upon the most perfect plan, and to avail themselves of the very best opinions and methods the science of the day can supply. We look forward, therefore, to the completion of this work as one of more than usual interest and importance.

CHURCHES, PUBLIC BUILDINGS, AND IMPROVEMENTS.

St. Saviour's, Southwark.—At a late public vestry in this parish the following resolution was carried:—"That the population of this parish (St. Saviour's) being upwards of 19,000, and the part of the church now capable of being appropriated for divine service being not only very inconvenient, but also very deficient in extent; and it appearing from the information of the parish surveyor (Mr. Rose) that an entirely new church might be built on the site and foundations of the ruins of the nave, or western part of the present edifice, the exterior of which new church might be made suitable to the appearance of the other parts of the present building, while the interior should be so constructed as to furnish the requisites of a church fit for a congregation of 2,000 persons; and with strict economy the whole of such new church might be built, fitted up with galleries, &c., the organ removed and replaced, the church lighted with oil or gas, and properly warmed, and the communication with the tower and other parts of the church completed, so that such new church should in every respect be fit for divine service, for a total cost of not exceeding 8,000*l.*, this vestry authorises the churchwardens to apply to the commissioners, under the act of Parliament, for a loan of 8,000*l.*, for the purpose of building and completing such new church."

Christ Church, Surrey.—This church, situated in Blackfriars-road, which has long stood in need of some very substantial repairs, is to undergo a thorough cleansing and repairing.

Bristol Cathedral.—The removal of the seats in the outer choir of our cathedral, which has been carried into effect, has already much improved the appearance of the interior. Among the intended improvements are the shutting up of the present north doorway (a substitute for a much more beautiful arch on the same side, which is to be re-opened), the construction of a grand western entrance, and the removal of the incongruous Grecian front to the old Gothic altar screen. On either side of the communion-table under the east window a mass of masonry has been removed, throwing open two beautiful arched recesses, and it is very probable that when the ornamental incumbrances to which we have referred are taken away, a similar and perhaps larger recess will be disclosed in the centre. The Very Rev. the Dean, we are told, by whose directions these improvements are being carried into effect, takes a lively interest in the restoration of this beautiful church.—*Bristol Journal.*

New Church at Wetherby.—The site fixed upon for this church is to the north of the town, near the Barley-field-lane. We believe the ground has been given by Mr. Greenwood, a large landed proprietor. The handsome donation of 300*l.* has been transmitted by General Wyndham, the lord of the manor.—*Leeds Intelligencer.*

The Monument to the Memory of the late Duke of Sutherland.—The colossal statue of his Grace, which has been four years in progress, will be erected on the summit of Benvraige, in the course of the ensuing fortnight. It is thirty feet high, and can be discovered at a distance of 80 miles. The artists employed in the work have had a handsome house assigned to them at Dunrobin by the noble relict of the late Duke, and a cast of the head of the statue has been placed, at the desire of her Grace, in the summer-house of the Castle.

The Statue of James Watt, by Sir Francis Chantrey, is now placed in the building erected for it in Union-street, Greenock. It is what is technically called an eight foot figure, and the posture is exactly the same as that of Watt's statue in George Square, Glasgow. The figure is of statuary marble, and weighs upwards of two tons, and the pedestal, which is of Sicilian marble, weighs about three tons. On the front of the pedestal is the following inscription from the pen of Lord Jeffrey:—"The inhabitants of Greenock have erected this statue of James Watt, not to extend a fame already identified with the miracles of steam, but to testify the pride and reverence with which he is remembered in the place of his nativity, and their deep sense of the great benefits his genius has conferred on mankind. Born XIX January, MDCCXXXVI. Died at Heathfield, in Staffordshire, August XXV., MDCCCXIX."

Park Improvements.—We do not wish to arrogate anything to our Journal that does not belong to it, but we cannot but remark, with great satisfaction, that the improvements suggested in the number of June last by our correspondent J. H., of the removal of the southern boundary wall of Kensington Gardens, and the substitution of an iron railing, is fast proceeding. Let the idea come from where it will, we are equally gratified, and we hope that this fall will see the removal of the trees from the front of the statue of Achilles.

FOREIGN INTELLIGENCE.

France.—It is said to be in contemplation to erect in the dockyards of all the naval ports of France steam-engines, with the requisite machinery for making bread and biscuit for the navy, instead of manual labour, as at present is the custom.

The new Suspension Bridge over the Danube, between Buda and Pest, which will be begun the next spring, is a colossal undertaking. Two piers of granite and the red marble of Neudorf, 35 feet thick, and 150 feet above the level of the foundation, will support the whole structure. There will consequently be three openings for the water to pass through, the middle passage being 640 feet in width, and each of those at the sides 270 feet, making in all 1,180 feet. The entire length of the bridge will be 1,600 feet. Cast iron beams will support the platform, which is to be 37 feet wide—viz., 25 feet for the carriage way, and 6 feet for each footpath. The whole will be suspended by 12 chains, weighing together upwards of 2,000 tons.—*French paper.* This bridge, we are happy to announce, is to be constructed under the superintendence of Mr. Tierney Clarke, whose abilities in this department of engineering are well known.

Cathedral at Cologne.—The King of Prussia has granted 10,000 crowns towards the repairs of the cathedral. The contributions to these works during the last year have only amounted to 2,124 thalers, of which the inhabitants of Cologne and its suburbs paid half. The amount of the collections in 1836 was no more than 972 thalers.

The beautiful Palace at Genoa, formerly occupied by Queen Maria Theresa, is about to be converted into a convent, having been granted by the King of Sardinia to the Society of Jesuits.

Portugal.—A company has been formed to navigate the Tagus and the Sadao, and the Sartorius steam-vessel has already been placed on the station.

Russia.—A canal, by which the first cataract of the Dnieper is avoided, has already been dug, under the direction of Lieut.-Col. Schypar, of the engineers. The works are commenced for rendering eleven other cataracts of the river navigable, and it is hoped that they will be completed by the end of August next year. Thus there is a prospect of a very easy communication between the Baltic and the Black Sea, and by means of the Don—between which and the Wolga a canal is begun—these two seas will have a communication with the Caspian. A company established last year for the navigation of the Dnieper has already a capital of 8,000,000 of rubles. (Qy.?) It is having several steamboats built, the engines of which are to come from England. The seat of the company will be at Kiew, where a large depôt is to be erected.

Bridge at Bordeaux.—When this bridge was built, Napoleon insisted that the arches should be sufficiently extensive to admit of a frigate passing through them without her masts. The soundness and utility of this idea has just been proved. The Chilian, 46-gun frigate, launched a few days ago, has been taken through the bridge, and moored off the quay, without the slightest accident.

Luxor Obelisk.—Cost of a single Stone.—The conveyance of this object to France cost nearly 40,000*l.* The law of the 27th June, 1833, granted 12,000*l.* for the embellishment of the Place de la Concorde, and the laying down of the obelisk, in addition to 2,000*l.* voted in 1832. In 1835, 5,600*l.* was paid for conveying the monument from the river bank to the centre of the place. This conveyance, the laying down, and the accessories, cost 22,400*l.*; the granite base cost upwards of 7,600*l.*; so that, altogether, the *one stone* monument has cost France an expense of more than 70,000*l.*

Paris.—Among the improvements of Paris contemplated, or in course of completion, we understand that the branch of the Seine which runs on the northern side of the Isle Louviers is to be filled up, and a quay is to be erected on part of the new ground, the rest being covered with houses. The alterations at the Hotel Dieu are to deprive it of only 300 beds, but the same number will be added to the former Hotel des Orphelins, in the Rue St. Antoine, now incorporated with the Enfans Trouvés, by the buildings annexed to that establishment. The embellishments of the Place de la Concorde are advancing towards completion. The two fountains will soon be finished; and the reservoir for supplying them is forming near the Barrière de Monceaux, to which the water is to be brought from the Canal de l'Ourcq. The pavement of the Rue Vivienne is relaying on a new principle, and the curb-stones are bevelled on their under surfaces, so as to form covered channels for the passage of water—an improvement long since needed in that crowded thoroughfare.

Naples.—We learn by a letter that numerous ordinances have been lately published on education. The director of the university has directed that in future the first principles of physics, chemistry, mechanics, agriculture, and navigation, shall be taught in the elementary schools. No master is to take an apprentice until the latter has attended one of these shools for twelve months at the least. Special sciences are to be taught at the colleges, and normal schools are to be established.

Failure of a Suspension Bridge.—A new suspension bridge over the Dordogne, at Beaulieu, in the Correze, was tried a few days since, but gave way under the weight put upon it, owing to a defect in the supporting piers, and fell, with its whole mass of road-way and chains, into the river. Fortunately no lives were lost.

German Scientific Association.—At the last meeting at Friburg, on the 25th Sept., it was agreed that the next annual meeting should be held at Pyrmont. A proposal for holding it at Hanover was rejected by a large majority.

Itinerant Associations.—The French Geological Society, which recently assembled at Porentruy, and has been exploring the Jura, has been every where received with the greatest attention. The towns of Porentruy, Delemont, Soleure, Bienne, and other Swiss towns, have deputed scientific men to do the honours of the country to the society. [We think that our associations might follow this example, and that they would be much better employed in a week's organized exploration of Cornwall, or any other geological district, than in enjoying "the feast of reason and the flow of soul."—*Editor.*]

Turkish Canal.—A firman has been issued to construct a canal to join the Danube and the Black Sea, which would abridge, by several days, the transit to Constantinople, insure the liberty of the Danube, and render unavailable the possession of the Delta of that river by Russia.—*Augsburg Gazette.* This refers to re-opening the old canal of Trajan, between Rasova and Kostendsche, and would shorten the navigation of the Danube by eighty miles. It is confirmed by letters from Servia.

Egyptian Polytechnic School.—This school contains 225 pupils. They are maintained by the government, and receive pay according to the number of years of study. 1st year, 8*l.* per annum; 2nd year, 10*l.*; 3rd year, 12*l.*; 4th year, 14*l.*; 5th year, 16*l.*

Egyptian Gold Mines.—The gold mines recently discovered in upper Egypt have been exceedingly productive, and it is expected that others will shortly be discovered. A commercial house at Trieste has forwarded eighty quintals of Idria to Alexandria, to purify the ore.

MISCELLANEA.

An Antique Tomb has been recently discovered in piercing a railroad tunnel at Rive de Gier, near St. Etienne. It was cut in the rock, and lined with oak several inches thick, and covered with Roman tiles. The whole was in perfect preservation, and from its size was evidently intended for two persons. It is not stated whether any remains were found in it.

Ancient Relic.—About a year ago we noticed the removal of the old house in Queen-street, believed to have been the residence of Mary of Loraine. Various specimens of curiously carved work in the shape of oak panels were then taken down; and last week, in making some repairs upon the house adjoining, apparently forming part of the above building, a massive oak door was discovered, between the panels of which two black letter MSS. were found, which bear all the appearance, in the absence of dates, of belonging to the period when these residences were originally occupied. The curious in these matters may see them at our office for a few days.—*Scotsman.*

Several columns, capitals, and other Roman antiquities, have lately been discovered beneath the soil near Guignes, in the Seine at Marne. They are in good preservation; and as the spot on which they have been found is by the side of a Roman road, it is probable that further discoveries will be made.

Guildhall Statues of Queen Elizabeth, Edward VI., and Charles I.—The statues of Queen Elizabeth, Edward VI., and Charles I., which were discovered some time since in one of the cellars of Guildhall, having been thoroughly cleaned, they were yesterday morning placed in the three vacant niches at the east end of this magnificent hall. The statue of Queen Elizabeth is placed in the centre niche. The statues are in an excellent state of preservation, and will considerably add to the grandeur of this ancient edifice.

A new Railway Truck, the invention of Mr. Robert Grant, of Maine, is important to all connected with the construction and management of railroads and locomotives, if it actually possesses the recommendations enumerated. In the first place, the truck is guided by the carbody with such mathematical precision, that the wheels will, on a smooth plain, without rails, or flanges to the wheels, trace any curve of not less than seventeen feet radius to the eighth of an inch. They require no more power of draught on a curve than on a straight line, and will entirely do away with all lateral action on the straight track, thereby dispensing with one quarter of the force of traction in that case, and in passing a curve with one half. It is impossible to run them off the track after the locomotive has passed safe; they cost no more than other cars, will last as long again, and will not wear out the track more than one half as fast; they will be more easy, every way safer, and one quarter, if not one-third, of the expense of constructing and working railroads will be saved.—*New York Commercial Intelligencer.*

Steam Fuel.—An experiment has been made, on board the steamer on the Trinidad station, of pitch, as fuel: it was found to answer beyond expectation. She was two hours on her passage to La Bren, from St. Ferdinand, but accomplished the return voyage in one hour and thirty-five minutes. The pitch was said to leave little refuse, and not to run through the grating bars, the flame being much greater than with coal. [Qy. Is this pitch the Trinidad asphalte?—Ed.]

Tin Theatre.—Some of our contemporaries give an account of a novel kind of structure recently erected at Boston. It seems that our American brethren are not contented with tin and copper roofs, but that they must also use the same thin material for their floors. The greater part of the details of the house are executed in iron or tin plate; the machinery, the pit benches, the boxes, galleries, and even the platform of the stage. It is said that the plates give a more brilliant effect to the painting and decorations, and that they possess another superiority over linen and canvass, by increasing instead of deadening the sound of the voice. To prevent any inconvenience from the sound of footsteps on the hollow floors they are lined with woollen, and the whole edifice is represented as being, in addition, fire proof. The architect is said to have met with complete success, and some of the German periodicals look upon this attempt as an example which may be productive of most excellent results in their own country.

Some extensive traces of Roman edifices have been recently discovered in the forest of Arothone, near Caudebec, in Normandy, and among them, at a depth of four feet under the soil, the Mosaic pavement of a large chamber of extraordinary beauty. Upon some fragments of the side walls still existing, vestiges of painting in fresco have also been remarked.

OBITUARY.

We regret to announce the death of Mr. Timothy Bramah, of Pimlico, which event took place on the 21st ultimo.

We also have to announce the death of Dr. Bowditch, of Boston, United States, the translator of the celebrated work of the Marquis Les Place, "On the Mechanism of the Heavens." Four volumes of the translation had been published, and the fifth was nearly ready at the time of the Doctor's death. He lived to examine the last proof sheet of the work the day previously to his death.

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 27TH SEPTEMBER, AND THE 25TH OCTOBER, 1838.

JOHN WHITE, of Haddington, North Britain, Ironmonger, for "Certain Improvements in the Construction of Ovens and Heated Air Stoves."—27th September; 6 months.

JOHN BOURNE, of the City of Dublin, Engineer, for "Certain Improvements in Steam Engines, and in the Construction of Boilers, Furnaces, and Stoves."—8th October; 6 months.

JEHIEL FORBES NORTON, of Manchester, Merchant, for "Certain Improvements in Stoves and Furnaces, and in Instruments or Apparatus for making the same."—8th October; 6 months.

HENRY DUNIGTON, of Nottingham, Lace Manufacturer, for "Improvements in Warp Machinery and in Fabrics produced by Warp Machinery."—8th October, 6 months.

GEORGE HADEN, of Trowbridge, in the County of Wilts, Engineer, for "Improvements in the Manufacture of a Soap or Composition applicable to the Felting and other Purposes employed in the Manufacture of Woollen Cloth and other Purposes to which Soap is usually employed."—8th October; 6 months.

CHARLES SANDERSON, of Sheffield, Steel Manufacturer, for "A certain Improvement in the Art or Process of Smelting Iron Ores."—11th October: 6 months.

MATTHEW HEATH, of Furnival's Inn, in the City of London, Esquire, for "Improvements in Clarifying and Filtering Water, Beer, Wine, and other Liquids."—11th October; 6 months.

JOHN WOOLRICH, of Birmingham, Professor of Chemistry, for "An Improved Process for Manufacturing Carbonate of Lead, commonly called White Lead."—11th October; 6 months.

JOHN FOWLER, of Birmingham, Gentleman, for "Certain Improvements in Preparing or Manufacturing Sulphuric Acid."—11th October; 6 months.

WILLIAM BROCKEDON, of Queen's Square, in the County of Middlesex, Esquire, for "A Combination of known Materials forming a Substitute for Corks and Bungs."—17th October; 6 months.

HENRY MEYER, of Piccadilly, Wax Chandler and Oil Merchant, for "Improvements in the Manufacture of Lamps."—17th October; 6 months.

ELIAS ROBINSON HANDCOCK, of the City of Dublin, for "Improvements in Castor for Furniture and other Purposes."—17th October; 6 months.

GEORGE HARRISON, of Carlton House Terrace, Surveyor, for "Improvements for Supplying Air for Promoting and Supporting the Combustion of Fire in Close Stoves and Furnaces, and for Economizing Fuel therein."—17th October; 6 months.

WILLIAM EDWARD NEWTON, of 66, Chancery Lane, in the County of Middlesex, Patent Agent, for "Improvements in the Construction of Bridges, Viaducts, Piers, Roofs, Truss Girders, and Stays for Architectural Purposes."—17th October, 6 months.

JOHN GEORGE BODMER, of Manchester, Engineer, for "Certain Improvements in the Machinery or Apparatus for Carding, Drawing, Roving, and Spinning Cotton, Flax, Wool, Silk, and other Fibrous Substances."—22nd October; 6 months.

WILLIAM JUKES, of Great Russell-street, Bloomsbury, for "A Mode of applying Ventilating Apparatus to Stoves conducted on Dr. Arnott's Principle."—22nd October: 6 months.

WILLIAM EDWARD NEWTON, of 66, Chancery-lane, in the County of Middlesex, Mechanical Draftsman, for "An Improved Method or Methods of preparing certain Substances for the Preservation of Wood and other Materials used in the Construction and Fitting-up of Houses, Ships, and other Works, which Improvements are also applicable to other useful Purposes."—22nd October; 6 months.

JOHN HENFREY, of Weymouth-terrace, Shoreditch, Engineer and Machinist, for "Certain Improvements in the Manufacture of Hinges or Joints, and in the Machinery employed therein."—25th October; 6 months.

NOTICES TO CORRESPONDENTS.

We have been obliged to postpone "Ralph Redivivus," and several other communications, in consequence of their arriving too late in the month; likewise the notice of several works for the same cause.

The outline report of Wexford Harbour requires consideration. We should like to have a sketch of the Harbour and proposed improvements, also a full report of both parties.

We shall feel obliged to the Profession for accounts of Works in Progress, New Inventions, and Discoveries; it would be doing us a great service if our Country Subscribers will forward us any Newspaper connected with the objects of our Journal.

Subscribers are particularly requested to make up their sets of the Journal, as the First Volume will be completed with the December number, which will contain an index, title page, and introduction. In consequence of this additional matter, the December number will be charged sixpence *extra.*

Books for Review should be sent early in the Month—Communications on or before the 20th—and Advertisements on or before the 25th instant.

A MACHINE CALLED A HEDGEHOG.

FOR REMOVING MUD, &c., IN RIVERS.

(Communicated by S. Lewin, Esq., C.E., of Boston.)

The accompanying drawings exhibit a plan and section of a machine called a Hedgehog, used in Lincolnshire to assist in removing the mud, &c., that accumulate on the land side of the sea sluices. By reference to the plan and description its action will be easily understood, the wheel revolves on the centre, and is pulled backwards and forwards by means of tackle connected with it; it is applied when the water is running through the doors into the sea, and found to act very beneficially. When put in motion it is attached to the stern of a barge, which is drawn by horses; and sometimes a barge is moored at a certain distance from the sluice where it is intended to be used, having a mechanical purchase fixed in the same, and the machine moved backwards and forwards by means of leading blocks and chains. But there are various methods of using it, by attaching it to horses or to a steam boat, &c. The whole of the wood work is made of English oak.

Fig. 1. Plan.

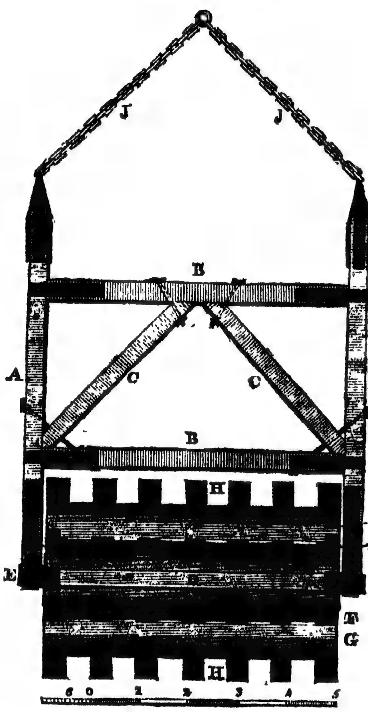

Fig. 2. Side Elevation of Frame.

Fig. 3. Transverse Section of Wheel and Spades.

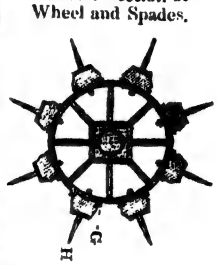

Fig. 4. Plan of Spades.

REFERENCE TO DRAWINGS.

Similar letters in each figure refer to similar parts.

A.A. Frame of timber, 6 by 4 inches, armed at the points with iron work, bolted through. B.B. Cross stays of timber, 6 by 4 inches, and 3 feet apart, connected to the frame by iron straps. C.C. Diagonal braces of timber, 6 by 4 inches, secured to the frame and stays by diagonal bolts. D. Shaft, of timber, 6 by 6 inches. E.E. Iron centres, upon which the wheel revolves. F. Iron work of wheel attached to shaft by iron arms, as shown in the section. G.G. Stocks of timber, 5 feet 11½ inches long, 6 by 3½ through which the iron spades are bolted to the iron wheel. H.H. Iron spades, 4 by 7 inches, placed 7 inches apart. J. Chain.

WOOD PAVEMENT.

MEMORANDUM ON PAVING STABLES. BY CAPTAIN ALDERSON, R. E.

(From the Papers of the Royal Engineers.)

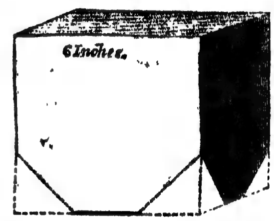
Constant repairs being required to the pebble paving of the stables at the cavalry barracks at the station (Brighton), and the usual mode of repair adopted, viz., relaying the pebbles in screened gravel, being found ineffectual, the following mode was resorted to with complete success.

The paving down the centre of the whole length of the stall, two feet in width, was taken up, and the ground excavated six inches deep throughout; a few half sovereigns, or six inch Purbeck stone pitchers, which happened to be at hand, were then placed on the part generally occupied by the fore and hind feet of the horse; the remainder was then filled in with concrete* to within one inch of the required level, and whilst the concrete was in a semi-fluid state, the pebble paving was relaid and rammed into it level with the half sovereigns, when the whole was grouted: it set in a couple of days, but was not occupied for ten. The pebble stones, thus firmly fixed in a matrix of concrete, are immoveable, and found to answer completely. The trial was on a sixteen stall stable. It has been constantly occupied since done without any complaint.

Laying paving or concrete foundation is of course not new, it is provided for in the schedules; but paving on it when in a semi-fluid state is so, as far as I know.

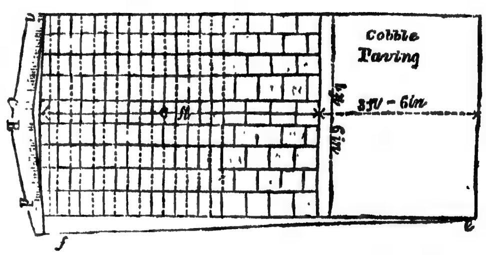
Though this appears to me the best mode that can be resorted to in pebble paving, I am of opinion that six inch yellow pine blocks Kyanized, placed on their ends diamond-wise on a bed of concrete, will be found both more economical as a paving, and infinitely better for the horses' feet and legs. I hope in a short time to be able to describe the best mode of laying these blocks: I am now trying different modes. I believe it is generally adopted in Russia, though I do not know either their dimensions or the mode adopted in laying them. My present idea is, that by taking off the lower angles at the four corners with an adze, so as to make the lower end octagonal, they may be laid like the pebbles in the concrete as a matrix.

Extract from Engineer Officers' Diary at Brighton, dated Jan. 3, 1838:—



"The wooden blocks for the pavement of the stalls in the stables are formed thus:—The upper surface being a square, and the lower an octagon, by taking off the lower corners with an axe; the blocks are then set in concrete from three to four inches in depth; they are set with mortar, and the pavement is grouted when set.

"The transverse grooves have answered most completely. They need not, I think, be made more than three or four feet from the rear upwards; that is, as far as it is ever likely the hind legs of the horse may stand, the fore leg being on the cobble pavement thus:—



"The dotted lines show the grooves, which are also made at the joints, making them every three inches. The course under the bail in each stall, and not shown, would be flat like the centre course at the stall, and this will make up the five feet to each stall.

"In consequence of the report that the stall laid with six-inch wooden blocks was found slippery, I was of opinion that transverse grooves, half an inch wide and deep, and three inches apart, would remove this complaint without destroying the principle. These grooves have been made, and by mistake longitudinal ones also: this I consider unnecessary; but several were done in the present instance before I was aware of it.

"The instrument by which this groove was made may be termed a bird's-mouth gouge, being a common gouge ground down.

"I consider the four-inch fall may be reduced one-half. The floor, it appears to me, will endure as long as the barrack, without once requiring repair: the size of the blocks may be regulated so as to accommodate the timber of which they are made; nor is it absolutely necessary that all the blocks be of the same size, so that *all* in the *same* course have one dimension, besides the depth the same: the depth should however, I think, never be less than six inches.

"R. ALDERSON, Captain Royal Engineers.

"Brighton, 11th September, 1837."

* The concrete was made in the manner usually adopted here in the sea-wall, as described by Lieut.-Colonel Reid, but without the pug-mill, viz.,

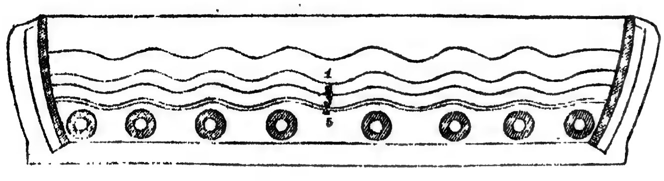
Part 1. Water lime slaked on the spot. 2. Fine sea sand, or gravel. 3. Shingle. The two latter ingredients are obtained from the beach; the former underneath, and the latter on the surface.

FILTRATION OF THAMES WATER AT THE CHELSEA WATERWORKS.

Communicated by Mr. James Simpson, Resident Engineer.

(From the Life of Thomas Telford.)

SECTION OF FILTERING BED.



REFERENCE.

1. Fine Sand.
2. Coarse Sand.
3. Pebbles and Shells.
4. Fine Gravel.
5. Large Gravel, containing the Brick Tunnels;—of which there are eleven under the Filter of the Chelsea Waterworks.

The process of filtering water on the extensive scale adopted at the Chelsea Waterworks being novel and interesting, as well as important, I am happy to communicate a general account of the success of the undertaking.

The managers of the Chelsea works had determined to prosecute some plan for rendering the quality of the water supplied by them unobjectionable; and in the spring of 1826 I commenced experiments and inquiries upon the subject, so that when Dr. Roget, Mr. Brand and Mr. Telford, the Commissioners of Inquiry, visited the works in the summer of 1828, they found the construction of filtering-works of some magnitude in an advanced state.

So little has been written on the subject of filtration of a practical nature, that the art of conducting the process upon a large scale was yet to be acquired, and improvements to be made upon the works at Glasgow, Manchester and other places, where it appeared that instances of failure, as well as of success, had occurred. Preliminary experiments were indispensable to warrant expenditure of capital on such works, and several trials were accordingly made on superficies exceeding one thousand square feet, to ascertain the most approved principle, and the fitness of the various materials proposed to be employed. All the modifications of lateral and ascending filters proved disadvantageous, difficulties were encountered in preserving the various strata in their assigned position, according to the sizes of their component particles; and effectual cleansing could not be accomplished without the removal of the whole mass of the filtering medium. All devices by currents, re-action of water, and other means, also proved either inefficient, or inconvenient and expensive.

The mode of filtration adopted at the Chelsea works is by descent, and the medium consists of fine and coarse river-sand, comminuted shells, and pebbles, and of small and large gravel. The materials are laid in a reservoir, their surface being disposed in ridges, which presents to the spectator an undulated appearance. The first experiments by descent failed; sufficient care had not been taken in the selection and separation of the materials. Explosions of condensed air in the tunnels for collecting the filtered water deranged the strata occasionally, and were obviated by air-drains. The filtration was, in one instance, stopped by the addition of fresh sand, without having previously removed the old sand, which should be applied as the upper stratum; although, in this case, the surface had been thoroughly cleansed previously, a film or puddle was formed on the original sand, and was sufficiently supported by the particles of sand to sustain five feet head of water, at first acting to impede, and eventually to stop the filtration. The process was greatly improved by the introduction of the small shells, such as are usually found at Shellness, the flat surfaces of which overlap, and assist in the great desideratum of separating the sand from the gravel, and thus tending to preserve the free percolation in the lower strata, which is essential for ensuring filtration sufficiently rapid for waterwork purposes.

The strata on the site of filtering-works, under the vegetable mould, consist of loam, sand and gravel, overlying the London clay to the depth of thirty feet. The sand and gravel contain powerful land springs, and the masses of ferruginous conglomerate they pass through are so great, that the water is of an objectionable quality; therefore, in constructing the basin to receive the filtering materials, it was necessary to exclude all the land water by clay and cement walling.

An excavation into the sand and gravel, of sufficient depth to admit of the water from the river flowing on to the filtering bed, would have involved too great an outlay; and this circumstance led to the construction of the basin, at a level which rendered pumping the water from the river unavoidable; but the consequent subsidence of the water, and the commandof a constant flow to the filtering-bed, are advantages which result from the expedient of pumping; and the interest of the money saved has more than compensated for the annual expense. The filtering-bed covers an area of one acre, and there is an elevated reservoir of nearly the same size. Reference to the accompanying sketch will explain the construction of the filter. The lower stratum of gravel contains the tunnels for collecting the filtered water. They are built with cement blocks, and partially open-jointed, two spaces of an inch and a half on the bed, and the heading-joint of each brick being open. The fine gravel, pebbles and shells, and the coarse and fine sand, are laid upon the large gravel.

The water is let on to the filtering bed at nine places, and the ends of the pipes are fitted with curved boards to diffuse the currents of water, and prevent the surface of the sand from being disturbed. The interstices in the fine sand being more minute than the subjacent strata, it is found that the impurities are arrested near the surface, and it has not been necessary to remove more than one inch depth of the sand at any one time of cleansing. This work is effected by scraping the surface every fortnight, and upon a careful examination it has been discovered that the sediment penetrates to the depth of from six to nine inches, according to the state of the Thames water; the greatest penetration occurring during the prevalence of land floods in the river. Notwithstanding this, however, it is not necessary to remove more than the depth stated, which contains the grosser impurities, the remainder tending rather to improve filtration by rendering the interstices between the particles of sand still more minute. From these observations it must not be inferred that the process is merely a fine mode of straining, for something more is evidently effected; an appearance resembling fermentation being discernible when the water is in contact with the sand.

The quantity of water filtered is from three to four thousand cubic feet daily' according to the demand. The undulated surface of the filtering-bed admits of parts of it being worked, and others drained; and it aids in cleansing, by admitting the grosser particles of the silt to slide down the ridges, and form a sediment easily manageable. The removal of the sand is effected by lifting portions of the fine sand in succession, and placing fresh sand of the same description underneath them.

REVIEWS.

A Bibliographical, Antiquarian and Picturesque Tour through the Northern Counties of England and in Scotland. By the Rev. T. F. Dibdin, D.D. With plates. 2 vols., large 8vo. London, 1838.

Dr. Thomas Frognall Dibdin is undoubtedly a first-rate coxcomb, a strange compound of black-letter pedantry and finical fiddle-faddle, singularly egotistical and pompous, yet clever and amusing: nor is he least of all amusing when he intends to be prodigiously sentimental or pathetic. One of his least excusable failings is his addiction to fulsome flattery and fawning; for his books exhibit more of the oiliness of the parasite then the unction of the divine, as these two volumes—perhaps we ought to say tomes—abundantly testify. With him every goose is a swan, if not absolutely a phœnix; and probably Mr. Emerson Charnly, of Newcastle, and Oliver Sumner, the bookbinder at York, stared not a little when they found themselves here recorded, the one as the "Veteran Emperor of Northumbrian booksellers," the other as a great "Bibliopegist Artist." However, we shall leave to others to notice the doctor's bibliomaniacal and bibliopegistical pursuits, contenting ourselves with culling from his "Tour" some scraps of architectural information, which we should have liked better had it not been so compressed and condensed. Some one of our correspondents therefore, we hope, will favour us with fuller particulars respecting the mansion of which the Doctor thus speaks:—

"On gently elevated ground, and about two miles from Grantham, we were struck with the rising Gothic glories of the residence of — Gregory, Esq. It is built on the Tudor plan of architecture, and no cost is spared for its continuance and completion in the most correct and splendid manner. I learnt that the drawing-room was one hundred feet in length; from the windows of which is seen Belvoir Castle, in all its pride and plentitude of effect. Mr. Gregory has the *rare* merit of being chiefly his own architect, with a thorough knowledge of the business in hand. Now and then, however, it is said that Mr. Blore whispers in his ear."

A drawing-room a hundred feet in length is certainly somewhat of a prodigy in these degenerate days, when the wealthy of the land ensconce themselves in coach-housed cottages; and if all the rest be upon a similar scale, Mr. G.'s house will be a magnificent affair. It is further to be hoped he is a Catholic, or else Welby Pugin will cut up his Gothic glories without compunction. With respect to the professional assistance Mr. G. has had, we know that although both Mr. Blore and Mr. Salvin have been employed by him, Mr. Burn, of Edinburgh, is the gentleman now engaged.

Respecting Belvoir Castle we are told, in a note,—

"The late Rev. Sir John Thoroton, chaplain to his Grace, was not only the principal architect of the exterior of the two sides of the castle, after the melancholy fire in 1816, but was also the planner of the greater part of the interior decoration. The destructive fire here alluded to burnt down two sides of the castle, which, with all the interior garniture, were not replaced under the sum of 90,000*l*. The pictures were necessarily an irreparable loss."

The paintings thus destroyed were upwards of one hundred, including, among other very fine ones, Reynolds's "Nativity."

Among the apartments are mentioned the "Regent's Gallery, a room of nearly one hundred and fifty feet in length, still left in an unfinished state;" and the dining-room, which "is sixty feet in length, with a ceiling (too low for such a length) most elaborately ornamented; though I wished the rosettes to have been gilded, and the high

relief to have been picked out in fawn or crimson colour." It is odd that the width of the room should not be stated, for it is that, and not its length, upon which justness of proportion as to height depends. Neither would it have been amiss to have informed us what the height actually is. We agree, however, with the Doctor, when he adds, immediately after, "a banqueting-room can scarcely be too gay or gorgeous." This maxim must be taken *cum grano salis;* for whatever may be the case in regard to a banqueting-room for state entertainments, a dining-room, even when sumptuous, should be in a somewhat more sedate and simple style then the drawing-rooms and boudoirs.

For the description of the Mausoleum at Belvoir, we must refer our readers to the book itself, merely saying that the building itself is by Benjamin Wyatt, and the statue of the late duchess and the children, by Matthew Wyatt.

Perhaps the Doctor is too apt to see every thing and every body quite *couleur de rose*, except, indeed, it be Mr. Britton; for though he refers two or three times to his account of York Cathedral, when speaking of that edifice, it is in the coldest manner, and without slipping in a single compliment, notwithstanding that he is so profuse of them to every one else, not forgetting another antiquary, of whom he says, "If the Minster (York) *must* crumble to dust, the glories of her architectural decorations will live for ever in the pages of Halfpenny!" Of compliments Mr. Richard Grainger, the Newcastle architect, has for one received his full *complement.* "It is difficult," says the Doctor, "to speak of extraordinary living merit without apparently transgressing the bounds of decorum, and even of truth. In the present instance the task is of yet more delicate execution; as the sensitive diffidence of this *Northumbrian Vitruvius* is apt to suggest the notion that offence may be felt where none is intended to be given. Away to the right and left with these flimsy and capricious phantoms! and let us contemplate this worthy and MIGHTY ARCHITECT as he deserves to be contemplated. His genius is his own, and vast as it is original. All the daring of the Roman mixes up in his achievements. He has a finger and thumb to span any space!" Really this is a pretty strong dose for the "sensitive diffidence" of Mr. Grainger, and we suspect that it was penned by the Doctor after his return from one of those "*symposia*" which he has registered with so much satisfaction of recollection. Passing over much that follows, and the whole of the newspaper account of the symposium given at the opening of the markets, October 22, 1835, on which occasion there were TWO THOUSAND GUESTS, we shall quote the following paragraph, as according better with our purpose:—

"Of the streets it were difficult to say which will preponderate—in width, length, and general splendour of architectural effect: but I learn that if the projected Grey-street—near which there is at this moment being erected a column 130 feet high, in honour of the illustrious nobleman whose name it bears—be carried into its meditated effect, it will be half a mile in length, and the width of Regent-street, with the difference (hear, and turn pale, ye Londoners!) of having the houses built of PORTLAND STONE. At present, what is just completed of *Upper Dean-street, Market-street, Clayton-street, Grainger-street, Pilgrim-street, Hood street, Nelson-street,* may be hailed only as the shadow of 'COMING EVENTS.'"

For our part, we only hope the Doctor is not mistaken—that he has not at all amplified what has been done, nor will prove to have been a too flattering prophet in regard to what is to be done. But we must say that the view of Grey-street, prefixed as the frontispiece to his first volume, renders us somewhat suspicious of him as to trustworthiness; for, unless it be strangely incorrect in itself, it fairly convicts him of misstatement, when he calls it as wide as Regent-street, for, according not only to the figures—and figures are, in such cases, far more likely to be diminished than exaggerated by a draughtsman —and also the size of the windows, the breadth of the street cannot be more than sixty feet. Nevertheless we do not find fault with it on that account, since the houses themselves thereby acquire comparative importance, whereas Regent-street is too wide for the height of the houses. The street at Newcastle has, it seems, the advantage of being built of Portland-stone—at least of stone, for that it should be Portland stone is not very probable; but then the buildings themselves are in a very flimsy and meretricious style of design—Regent-street at second hand—showy, common-place, without the slightest evidence of that originality for which the Doctor gives the architect such ample credit. There is not a single elevation—at least not among those shown in the view—that possesses the merit of any novelty whatever. Besides which, though there is no lack of Corinthian columns, a great many of the houses have very ordinary plain fronts, without any dressings whatever. To be sure the Doctor has very prudently confined himself to general praise, and had he done no more than commended the new streets and buildings at Newcastle as extensive and spirited undertakings and improvements, we could have agreed with him: not so when he launches out into a rhapsody of admiration so fulsome that it almost becomes irony. His own reputation, as a critic in matters of art, is not at all likely to be improved by his squandering away his admiration so freely. With this hint to him, and advising him to be far more chary of his praise for the future, if he would have any value attached to it, we now take our leave of the Doctor—for the present at least—as we shall probably return to him in our next number, and give some of his remarks on the architecture of Edinburgh and Glasgow.

The Steam Engine: its Invention and Progressive Improvements. An Investigation of its Principles and its Application to Navigation, Manufactures, and Railways. By THOMAS TREDGOLD, C.E. A New Edition, enlarged by the Contributions of Scientific Men, and extended to the Science of Naval Architecture. Edited by W. S. B. WOOLHOUSE, F.R.A.S. Vol. II. London: John Weale, 1838.

We have, on occasion of two reviews of the first volume of this work, availed ourselves of the opportunity of doing full honour to the memory of Tredgold, and of expressing our satisfaction with the compilation to which his name is attached. We feel pleasure, therefore, in seeing the conclusion of labours so happily begun, and so succesfully carried out, the more so as there is no period at which this second volume could appear more opportunely than at present. The aspect of political affairs gives a new interest to the subject of steam naval architecture, for a conflict must infallibly call into action, principles which may overturn all the established instruments of hostility, and give a new face to the science of warfare. Such an event would be important, not so much for its probable effects on the enemies of liberty and civilization, as for its influence on the state of war generally.

One of the main features of this second volume is steam naval architecture, and the treatment of it shows a correctness equal to the research employed. We regret, however, that on more than one occasion the Government has shown a narrow and self-injurious feeling, in refusing to submit to the conductors information on many points, which were important to the elucidation of their researches. We know of no motive beyond some petty office jobbing, which can be assigned for such a dereliction of duty to the national interests, for by the result of these labours the Government are more to be benefited than the profession, by whose exertions they are contributed. That the naval administration are desirous of keeping information for their own purposes, is a supposition gratuitously absurd, for by no outlay can they ensure the services of men of science sufficiently to keep all knowledge under their own control, or even as much as is exhibited in the work now before us. We trust, therefore, that on future occasions a better spirit will be manifested, and that it will be remembered that here, as in other departments of shipping, it is on the mercantile marine that the resources of war are founded. The Government seem well alive to the general importance of this arm of warfare, and while several of our dockyards are actively supplying new vessels, a general care has been taken to supply those already existing, with artillery of heavier calibre and wider range. We have little doubt that the shells of the new sixty-eight pounders will be found as formidable antagonists as the long-toms of sharp built cruisers, and that the old sailing vessels will be driven from the ocean, on which they will only be helpless victims to the range and weight of the wind-unembarrassed steamers. It is fortunate for us, that of all nations we shall feel the change of warfare least, for our boundless resources of iron and coal, and the skill of our workmen point out for us future security, beyond the present possession of the greatest tonnage of steam sea-going vessels.

Having expressed our sense of the service rendered to the nation by the information communicated on this department, our readers will perhaps feel desirous of examining some portions of a work abounding so highly in interest and instruction. The first portion is occupied with a description of the plates, which are exceedingly well executed, and confer great honour on the spirit and management of the publisher, being executed with a beauty and neatness which appear almost too finished for the low price of the work; while some of the wood cuts are of a magnificent size, without being subject to the reproach of unnecessarily occupying space. The descriptions are generally extremely clear and minute, particularly that of Stephenson's locomotive, the details of which are illustrated in the text by wood cuts, and so extensively elaborate, that an engine might be constructed from them. In the plates representing Maudslay's engine, at Chelsea Waterworks, this interesting subject is rendered defective from the omission of a ground plan of the machine; and we regret to say that such defect is too common in mechanical works, as if a ground plan were less necessary in this class of work than in architecture. In the extract which we subjoin we perceive an instance of sparring between the contributors, which seems to be carried on throughout the work, and tends to diminish our dependence on the result of their exertions.

The American contributor, among others, suffers from this inhospitality. There are three papers on paddle-wheels, and the disjointed effect of their labours is, that Barlow is attacked by Mornay, and this last again by the Editor; while the reader is left at the end of the conflict to decide on which he will not believe. We deprecate this puerility, it is unworthy of the work, it is derogatory from the cause of science, and it is particularly ungracious and impolitic towards a member of a kindred nation, which, if weak, we ought to support rather than to abase. We call the attention of the editor to these circumstances, to remind him that, however well he may have done his duty as a man of science, there is a minor degree of acquirement, which ought always to maintain a due degree of courtesy among the learned, and secure for them that respect from the world, which to maintain they must show towards each other. Our readers will perceive something of the nature of this rivalry in the description which we now extract of the Ruby steam boat.

ENGINES OF THE GRAVESEND PACKET RUBY.

This celebrated vessel, undoubtedly the fastest in Europe, and perhaps in the world, was built by Mr. Wallis, of Blackwall, near London, in the year 1836, from the designs and specifications of Mr. O. Lang, jun., of her Majesty's Dockyard, Woolwich. The engines were made by Messrs. Seawards and Co., of the Canal Iron Works, near London.

The very great success of this vessel, she having beaten all competitors from the time of her starting to the present, may be attributed to two principal causes:—

First, to a most judicious arrangement in the form and construction of the vessel, by which the quantity of materials used in the building are brought so to bear upon one another, that each piece performs the office assigned to it; and no more timber is used than what is requisite to give the ship the necessary strength and solidity. From the method of planking which is adopted, consisting of three thicknesses of oak placed diagonally and longitudinally, the vessel is completely trussed from end to end, and at once combines strength and lightness in an eminent manner. The length of the Ruby is 155 feet between the perpendiculars, 19 feet beam, and 9 feet 6 inches depth of hold; she will carry with ease 800 passengers. When launched she drew about two feet of water. Her after-cabin is 33 feet long, and will dine 100 passengers; the ladies' cabin is about 15 feet long, and the fore-cabin 33 feet.

Secondly, her superiority is attributable to her engines, which consist of two fifty-horse power engines (100-horse power the two), in the making and fixing of which every care was taken to have them as light and efficient as possible, without endangering their stability; and the calculation of weights and of displacement was so nicely adjusted, that when the whole of the weights were on board, and the vessel equipped for service, her real draught of water, 4 feet fore end and 4 feet 6 inches aft, was within a quarter of an inch of the builder's estimate. The weight of the engines complete with the water in the boiler is exactly 90 tons 5 cwt., being about 18 cwt. to the horse power; the diameter of the cylinder is 40 inches; length of stroke, 3 feet 6 inches; diameter of outer edge of paddle-wheel, 17 feet; and length of board, 9 feet 3 inches, and width 15 inches; with a dip of 17 inches with 200 passengers on board: then the speed of the engines is 30 strokes per minute, the pressure of the steam being only 3½lbs. above the atmosphere. The speed of the piston is therefore 210 feet per minute, the speed of the outer edge of the paddle board is nearly 20 miles per hour, and the speed of the vessel through still water by repeated trials is exactly 13½ miles per hour.

It is a remarkable fact, that from the first day of trial up to the present time, this boat has not varied her speed one-twelfth of a mile per hour; she has neither increased nor lost her speed. This is mostly to be attributed to the fact of the engines being in a most perfect state when set to work, but more particularly to the use of the patent slide valves on board of this vessel, and which after two years' working have been found as perfect upon their faces as when first put together; a further proof of their superior working is evinced by the vacuum in the condensers of the engines having never varied one-fourth of an inch, remaining constantly between 28¼ and 28½. This is ascertained by barometers attached to each engine, which are not affected by the atmosphere, and makes the vacuum as perfect as possible; for supposing the waste water, as it leaves the condenser, to have a temperature of 110 deg., which is equal to 1½ inch of mercury (see Professor Robinson's experiments), when added to 28¼ it gives 29¾, the usual height of the marine barometer in fine weather.

The safety valves are arranged upon the plan invented and used by Messrs. Boulton and Watt a long time since, and now generally adopted by the engineers of London. They are so arranged that no one on board can possibly have access to them; the engine man can at pleasure open them and let the steam escape, but he has no means by which he can keep them down, beyond the weight placed upon them by the engine maker, which weight is, as before stated, 3½lbs. on the inch; and it is a curious fact, that this boat has attained the great speed named, with this small pressure, while in a variety of instances vessels from different outports, working with high-pressure steam, and with the safety valves loaded *ad libitum* by the engineers and captains, have never been able to approach her in speed. This clearly proves, what the late Mr. Watt demonstrated long ago, that the most efficient, safe, and economical mode of working steam engines for marine purposes is at a pressure of from 2½ to 3½lbs. on the inch. At the same time, for single acting pumping engines there is no doubt an advantage gained by the judicious use of high pressure steam, say of 30lbs. on the inch, working expansively, with boilers properly constructed; but which boilers, for many reasons, are not at all fit for steam vessels: in fact, almost all the melancholy accidents that have lately occurred to steam boats by the explosion of their boilers, have been caused by the injudicious application of high pressure boilers to marine purposes.

It is here worthy of remark, that the Americans, who claim to propel their vessels at the high speeds of 15, 16, and in some cases 18 miles per hour (which, by-the-by, has been amply contradicted in this work by an able American writer, who states the greatest speed through still water attained by the best American steamers, he believes to be in one instance 14 miles per hour, but that the rest of the New York boats do not come up to this), state that the principal cause of their alleged triumphs is owing to the use of high pressure steam, used expansively; the causing the pistons of very long stroke engines to move at the rate of 300, 400, and sometimes 600 feet per minute; and lastly, to the superior form of the bows of their steamers, which are built so as to glide over the water instead of cutting through it.

In the case of the Ruby, in all these important matters she is decidedly the reverse of the Americans; the piston only travels about 210 feet per minute, very low pressure steam is used, the stroke of the engines is very short, being only two inches more than the diameter of the cylinder, and the form of the bow is decidedly that which will cut or divide the water without the least tendency to ride over it, inasmuch as this vessel's bow is shaped like a knife being as long on the keel as at the water's edge within two feet.

Judging from these facts, it will be seen that high pressure steam, length of stroke, and prow-shaped bows, qualities so loudly extolled by the Americans, are not all necessary for speed, but, on the contrary, the first two are positive nuisances; the length of stroke rendering the vessel an unwieldy, ill-contrived machine, totally useless for the purposes of sea navigation, as events have proved; while the high pressure steam system has been the means of filling the journals with those ever-occurring, heart-rending, and sickening details of hundreds and thousands that are being yearly sacrificed to ignorance and prejudice, by attempting to do that by the dangerous use of high pressure steam which can be so well effected by steam of a low pressure, and that too at one half the consumption of fuel.

The limits of this paper will not permit the writer to digress upon the subject of consumption of fuel, except by stating, that in no instance has the use of high pressure steam applied to an engine for rotary purposes ever been attended with economy of fuel, but the reverse; and it is not a little singular, that in this age, even in this year, northern engineers are imitating the Americans, by the use of the long stroke and high pressure steam, in the Thames, which one would think might have been spared this pestiferous curse. The results have been, and are, that the short stroke engines are propelling the boats, both sea and river class, faster than the long stroke ones. This length of stroke has been obtained by the placing of one half the machinery upon deck, some 12 or 14 feet high, and thus making the vessel frightfully crank and most unseemly to look at, while in vessels going head to wind, it exposes some hundreds of square feet of surface to be acted upon as a back sail.

The great danger of high pressure steam will be evident to every one, when it is recollected that within the last three years three different vessels have had dreadful explosions, viz., two on the Thames and one at Greenock (besides some less fatal ones in different parts of the north), by which more lives have been sacrificed to the Moloch of high pressure steam, than has ever occurred with low pressure steam during the whole progress of steam navigation, extending now almost to a period of forty years, and in the course of which nearly 3,000 steam vessels have been fitted out and successfully worked.

We have not room to extract farther from the extensive series of descriptions, but we refer the reader to the work, where he will find all necessary information respecting steam boats and locomotive engines.

The second volume proper begins with the sixth paper of the Appendix, which is by Professor Renwick, on the steam boats of the United States. We select from this interesting communication the portion explanatory of the superior speed of American vessels, which is the subject of the comments of the previous extract.

The writer made, in the "New Philadelphia," one of the most remarkable passages ever performed. Leaving New York at five o'clock P.M., with the first of the flood, he landed at Catskill, distant 111 miles, a quarter of an hour before midnight. As passengers were landed and taken in at seven intermediate points, the rate at which the passage was performed was not less than 18 English miles per hour. Now, as the current in no case exceeds 4 miles per hour, the absolute velocity through the water must have been at least 14 miles.

In obtaining these velocities of thirteen miles and upwards per hour, it does not appear that the force of the engines employed exceeded that which had been used in some American vessels which had far less speed. Neither was the relation of the power of the engine, estimated in the usual manner, to the tonnage of the vessel, greater than that found in European steamers, whose velocity does not appear, at that time, to have exceeded 10 miles per hour. Besides, it cannot be denied that the advantage in the finish and workmanship of the engines was on the side of the European vessels. We may therefore inquire to what circumstances it was owing, that a rate of speed, which a high British authority has very recently declared to be incredible, should be actually obtained. We ascribe this chiefly to the great difference in the principles which governed the structure of the engines in the two different countries. In the modifications of the original form of the engine of Fulton, the English engineers, whose efforts were principally directed to the navigation of stormy seas, thought it indispensable that the machinery should be included beneath the deck of the vessel. The stroke of the piston and the length of the crank

were therefore diminished below the proportion originally chosen by Watt. In America, the vessels being principally intended for the navigation of rivers, no such change occurred; and when it became necessary to make the "New Philadelphia" compete with vessels driven by more powerful engines, Stevens increased the length of the stroke and of the crank. The new relation between the diameter and length of the cylinder thus obtained, was followed, or even exceeded, in all subsequent engines. No change was made in the dimensions of the boiler, but the additional force was obtained by causing the steam to act expansively. The latter method was attended by an anomaly, which is however readily explained, when it is considered that the relative velocity of the circumference of the wheel is constant. It was not found that the steam, although cut off, at first at half stroke, was much increased in tension. The most obvious effect of the method was an increase in the velocity of the piston, by which the steam was prevented from accumulating.

When we consider the wheel as a body revolving on an axis, and which meets with a resistance, whose resultant is applied to a point at no great distance from its circumference, it will be obvious that there will be a point, to which, if the crank be applied, the whole force of the engine will be exerted to overcome the resistance; but if the crank be applied to any other point, a part of the force will be wasted upon the axle itself. Now, even in the long stroke usual in the modern American engines, it does not appear that the crank extends as far as this most favourable point; but in the short stroke of the English engines a large proportion of the whole power is lost.* This advantage is, however, at present less sensible in the American steam boats; for the principle of using cylinders of great length having been introduced, the next step was to increase the diameters of the wheels. The object intended to be gained by the latter change was an increase in the velocity of the circumference of the wheel, for the constructors of steam boats seem to have reached the conclusion that every addition to this velocity would add as much to that of the vessel. In one instance the diameter of the water wheels has been increased to 30 feet, and the stroke of the piston to 12 feet.

As an additional means of obtaining high velocities in the piston, the dimensions of the valves and steam pipes of the American engines have been increased beyond the proportion used by Watt. The flow of the steam from the boiler is thus rendered more rapid, and the velocity of the piston increased in like degree. We have already stated that the steam is cut off, and thus caused to act expansively: the advantage thus obtained is analagous to that derived from the same method in the pumping engines of Cornwall.

As an accessory, and one of no little importance, we may mention the form of paddle wheel originally introduced by the younger Stevens, but now universally adopted. The form of this may be readily understood, by supposing a common paddle wheel to be cut into three parts, by planes perpendicular to its axis; that one of these being supposed to remain at rest, the second is moved through one-third, and the third part through two-thirds of the space intervening between two contiguous paddles.

The triple wheel of Stevens does away the principal objection which can be opposed to the common paddle wheel, namely, the long interval between the successive strokes of the wheel against the water, and their violence.

In vessels of small dimensions the same principle is applied, but the wheel is only double, instead of being triple.

The velocity of the pistons of engines used for manufacturing purposes is about 200 feet per second. In the "North America" this velocity was carried up to 384 feet, and the rate is now exceeded in many of the newer vessels. Thus, in the steam frigate "Fulton," the velocity of the piston is 450 feet, and in the "Cornelius Vanderbitt" and "Highlander," as much as 600 feet per second.

The professor thus speaks of the defects of the American vessels :—

One prominent mistake, however, appears to have been committed in the vessels recently constructed for the navigation of the ocean in the United States. Departing from the practice, which had become sanctioned by successful usage, of employing two engines placed upon the wheel guards, a single one has been substituted.

The use of a single vertical engine of long stroke is attended with another difficulty, namely, that it requires a large opening to be left in the deck of the vessel, which cannot be sufficiently defended from the influx of the sea; for the bulkheads which surround it, cannot be rendered strong enough to resist a violent wave.

After all, the main objection to the present model of American steam boats, when considered in their fitness for the navigation of the ocean, is the weakness inherent in the great proportion which their length bears to their breadth and depth.

The following is an account given by Mr. Renwick of a vessel, which has been some months in preparation in the port of New York, for the purpose of running between that city and Liverpool :—

In this vessel a new form of boiler has been introduced, the principle of whose action is, that the combustion shall be maintained by air forced into a furnace without a chimney, and that the air, after acquiring, by the joint effect of compression and elevated temperature, a tension equal to that of the steam, shall open a valve by which it may join the steam in its passage to the valves of the engine. A sufficient number of experiments have been performed with this boiler, to show that it will produce a given effect at a vast saving of fuel, but various practical difficulties seem to oppose its perfect success.

* The author must here allude to the friction caused by the pressure on the shaft: no loss of power can otherwise result from the mechanical arrangement.—*Editor of Tredgold's Steam Engine.*

The conclusion of the Professor's remarks exhibit a spirit of candour which we should have liked to have seen manifested towards him :—

In conclusion it may be stated, that in respect to speed the steam boats of the Hudson exceed any others, have attained a velocity which is hardly believed to be possible in Europe, and are for the navigation of rivers unequalled. The same principles, modified according to the circumstances of the case, may be applied to give a greater velocity to vessels intended for the navigation of the ocean than has yet been attained by the English steamers. On the other hand, the vessels constructed in the United States for speed, want some of the essential properties of good sea boats. In the competition and honourable rivalry between the engineers and naval architects of the two countries, which the voyage of the "Great Western" is likely to call forth, the advantages of the methods which difference of circumstances has brought into use in England and the United States will probably be combined. We may therefore hope to see the rapid motion of the American vessels planned for river navigations, united with the strength, safety, and sea-worthy qualities of the British steamers.

The seventh paper is one of those previously mentioned on paddle-wheels, by Mr. Mornay, who, in an elaborate comparison of the several varieties, appears to prefer Morgan's improvement. We perceive, by-the-by, in the "United Service Magazine," a statement of a recent failure of paddle-wheels in H. M. steamer Megera, the particulars of which will be found in another part of the journal.

The eighth paper is on "Watt's Indicator," and the ninth on "Howard's method of Vaporization." The tenth paper is an able essay on the "General Theory of the Steam Engine," by the editor, and containing, among much other interesting matter, some remarks on rotatory engines.

The eleventh, similarly, by the editor, under the title of "Rules for calculating the Steam Engine," gives a complete system of practical steam arithmetic. Among many interesting objects, we find that the following extract will give the most available specimen of the treatment of the subject :—

POWER.

To find the power of an engine.

RULE.—Multiply double the length of stroke by the number of strokes per minute, and we get the velocity of the piston per minute.

If the engine works expansively, the mean effective pressure must be found by the previous rules.

Multiply the square of the cylinder's diameter in inches by the mean effective pressure on the piston in lbs. per square inch, and by the velocity of the piston; point off three figures and divide the product by 42, and the quotient will express the number of horses' power.

We have thus gone through the volume; but although we trust we have done full justice to it, we must refer the reader to the book itself to obtain a clear idea of its value. The greatness of such a work is a plea against hypercriticism, while the remarks which we have made will assure every one that we pay an honest tribute to the publisher and the editor when we assert, that it does as much credit to the public spirit of the one, as to the scientific acquirements of the other.

Transactions of the Institution of Civil Engineers. Second Volume. London: Weale, 1838.

The profession of civil engineering as a branch distinct from architecture dates only from a late period, and is one of those results of division of labour consequent upon our social progress. The idea of its association with architecture at any period, rested always upon a misconceived basis, for although it be true that in many instances both classes of professors operate upon the same materials, yet such circumstance by no means necessitates a bond of union; but may rather tend to show the distinctness of purpose. It is by confounding the architect with the builder and the mason, it is by this mingling of the operations of mind with those of matter, that we are often left in hesitation whether we should class a work as of architecture or of engineering. The professions have a connection in some studies, and may even in some cases pursue the same operations; but such facts no more tend to establish an intimate and indissoluble union, than the mutual study of medical jurisprudence to assimilate surgery and law. This division of pursuits has doubtless contributed no less to the mental progress than to the mechanical proficiency of the two classes; for if architects have more to deal with what is beautiful, so, on the other hand, engineers have greater scope in the colossal and sublime. If one be the lyric poet, the other is the epic, of the constructive arts; and it may be questioned whether an architect would attribute equal glories to the pyramids of Egypt, as to the basilica of St. Peter's or St. Paul's Cathedral. In the periods of the works of Sir Christopher Wren, the old bridges on the river, or the wall and terrace of Somerset House, we perceive little distinction made between the two professions; nor perhaps did an effective separation take place until the epoch of the great mania for canals,

at the end of the last century, which raged with a fury equal to that for railways in the present day. As it is, the result must necessarily be in the development of public works, that a still farther ramification must take place, and necessarily promote the improvement of engineering. What, indeed, can be a greater anomaly, than to expect a similar success from the same man in works so dissimilar as roads, bridges, and harbours? It is not that great minds may have succeeded equally in all branches, but that little minds, the staple of the world, must fail. It is not the universality of a Homer, a Shakspeare, or a Milton which denies, but, on the contrary, by exception confirms the rule. But to justify their independence, the profession must not, like lawyers, live only on old precedents; but, by the exertions of their inventive faculties, vindicate their claims to genius and their standing in the learned world. They must remember that they belong to a body which in modern times has produced Smeaton, Brindley, Rennie, and Telford, not to speak of its mechanical members, and which has most powerfully contributed to civilization by annihilating space and vanquishing the elements; which has thrown into the shade powers confirmed for tens of centuries, surpassed the fleetness of the horse on land, and placed us beyond the caprice of wind upon the ocean.

Among the features most worthy of interest in the career of engineering, are the joint contributions of the constituted body of its members, for it is to this volume that men of science will naturally have recourse, to ascertain how far the mental progress of the profession is commensurate with the just expectations of the public. We feel happy, therefore, in witnessing that this record shows a spirit of research and ability fully satisfactory, and particularly when we consider that the leading members of such an active profession, like general officers in a campaign, have little opportunity to register their opinions but by their works. In the volume now before us, the distribution of the subjects necessarily preventing any general view being taken of it, we must, on the present occasion, glance at the contents, and reserve for a future period a more discriminating examination of its parts.

The first paper is an Account of the Bridge over the Severn, near the town of Tewkesbury, designed by Telford, and communicated by W. Mackenzie, M. Inst. C. E., with three plates of the bridge and details. We know that the works of Telford are considered by many of the profession as good precedents, and undoubtedly in many cases very properly so; but we should wish them to observe, that too frequently the grandeur of the main feature of his designs is frittered away by the pettiness of its accompaniments. Telford had no eye for effect, but, having dashed out a leading object, he left all the rest to fate, and the consequence is that there is hardly one of his designs that we can recommend as a whole, for they look too often like colossal Gothic works, disfigured by the additions of an inferior artist. In the instance now before us, although it is a work of great merit, we regret to see it so much degraded by inattention. To the single arch of 170 feet span, and 16 feet 6 inches rise or versed sine, there is appended a collection of most incongruous and inappropriate lancet-shaped land-arches; and although there is great merit in the main arch and its details, yet these disfigurements make it look like a superior picture in a frame of ubbish.

Paper II. is *a Series of Experiments on different Kinds of American Timber, by W. Denison, Lieut. Royal Engineers, &c.* The author states that his object in making these experiments was twofold; in the first place, to establish some proportion between the strength of different kinds of American timber, and then to reduce them to a common standard, by reference to Mr. Barlow's experiments on European timber, so as to enable him to supply the place of the constant factors, which enter into the rules or formulæ by which the dimensions of timber for different purposes may be calculated with some degree of correctness; and in the second place, to ascertain the difference, both in dimension and strength, made by seasoning, or by difference of age, or position in the tree. The author then proceeds to detail the manner in which he made the experiments, and gives the result in a table, containing the details of 91 experiments, which were principally made on pieces of wood 24 inches long and about an inch square. This is a laudable object, but we wish we could se a series of experiments made upon a more enlarged scale than upon these bits of match wood, for the results produced, we fear would be wofully different. The Institution would do well were they to vote a sum of money for performing a series of experiments on an extensive scale, such as upon battens, deals, planks, and timber from 5 feet to 20 feet in length, and of different countries. Here we should have something tangible and practicable, something on which the practical man might place dependence.

Paper III. is *on the Application of Steam as a Moving Power; considered especially with reference to the Economy of Atmospherical and High Pressure Steam, by George Holworthy Palmer, M. Inst. C. E.* In this paper the author affects to regard with astonishment the official returns of the duty of 10 or 12 of the Cornish engines, and attempts to prove the impossibility of their performing any thing like the duty which they are reported to execute. His deliberate opinion, he states, is "founded on theoretical (?) and practical experience;" but he does not adduce one practical instance relating to a Cornish engine to support his theory; and to prove the assertions of the opposite party, Mr. Palmer winds up his paper with the following:—

Upon what principle, then, permit me to ask, can the Cornish engines perform so much more duty than all the other engines. Strong, indeed, should be the evidence that ought to outweigh or cancel the foregoing laws of nature, and induce this Institution to sanction statements of duty more than double that of the best Watt engine, and still more, surpassing the limits Nature has assigned steam to perform (under circumstances over which man has no control, the atmospheric pressure), unless, as before premised, the Cornish engineers can convert, with 7lbs. of coal, more than 62½lbs. of water from 40 deg. F. to atmospheric steam; and unless highly elastic steam can be applied as a first mover without converting sensible into latent caloric.

Really this language is not very complimentary to Captain Lean, Mr. Taylor, Mr. Henwood, Mr. Wicksteed, and others, whose evidence does not seem to be sufficient for Mr. Palmer; but we trust the practical experiments made by Mr. Wicksteed in Cornwall, and related by him in the present volume, will soon be put to the test in London, for the satisfaction of Mr. Palmer and his anti-Cornish engine associates.

A steam engine, with a cylinder eighty inches in diameter, is nearly completed at the East London Water-works, and in few days Mr. Wicksteed will have a practical opportunity of dispelling the theoretical mist from the eyes of his adversaries, who cannot see the difference in working of a steam engine with its boilers, pipes, and cylinders well clothed, to prevent the loss of heat by radiation; nor are they aware of the difference in the construction of boiler furnaces, the manner of feeding them, the qualities of coal, and many other accessaries, each of which makes important differences in the consumption of fuel; and their combined effect, no doubt, will account for the vast difference in the cost of working different steam engines.

Paper IV. is *a Description of Mr. Henry Guy's Method of giving a true spherical Figure to Balls of Metal, Glass, Agate, or other Hard Substances*, which paper we shall notice on a future occasion.

Paper V. is *on the Expansive Action of Steam in some of the Pumping Engines in the Cornish Mines, by W. Jory Henwood*, of which paper an outline was given in Journal No. 7, page 169. Appended to it are several tables, showing the proportions of the engines, and the quantity of fuel consumed. The author gives the following as

The work accomplished for a certain expense.—The foregoing details supply all that is requisite for this inquiry, except the prices of the materials consumed; these were coal, at the rate of forty one shillings for seventy two measured bushels; grease, forty-five shillings and sixpence per 112lbs.; and oil, four shillings and two pence per gallon; at which rates the results

Huel Towan, Wilson's engine, 1085 tons;
Binner Downs, Swan's engine, 1006 tons;
East Crinnis, Hudson's engine, 870 tons;

lifted one foot high for the expense of one farthing.

Paper VI., *on the Effective Power of the High Pressure Expansive Engines in use at some of the Cornish Mines, by Thomas Wickstead, M. Inst. C. E.*, we have given at full length in another part of our Journal. At a period when there is so much controversy and doubt regarding the economical working of Cornish engines, this paper will be read with great interest, and the more so as Mr. Wicksteed is quite unconnected with any party in Cornwall. Being engaged professionally, and having a responsible duty to perform on behalf of the company of which he is the engineer, he took every reasonable precaution in managing the experiments, and obtaining correct results, which proved perfectly satisfactory, and confirmed the previous reports which had been made. This report led to that company purchasing an engine belonging to the East Cornwall Silver Mining Company, which has been removed to London, and erected at the East London Waterworks, Old Ford. It is expected to be completed in a few days, we hope to be able to give a full account of its performance in our next number.

Paper VII. contains *a Description of the Drops used by the Stanhope and Tyne Railroad Company for the Shipment of Coals at South Shields, by Thomas E. Harrison, M. Inst. C.E.*, accompanied with drawings and working details of the construction. This machine, if we may so call it, may be easily and advantageously adapted for railways, when the stations and depots are considerably above or below the

common roadways, as possesses considerable ingenuity in its construction, and appears to be well adapted for the purposes to which it is applied.

The mode of shipping coals, shown by the drawings, was made the subject of a patent by the late William Chapman, of Newcastle-upon-Tyne, in the year 1807, and it is one of those instances in which the patentee, either from prejudice or some other cause, received little remuneration for an invention which has been the means of saving thousands to the coal owners on both the rivers Tyne and Wear; for although it was almost entirely neglected during the continuance of the patent, it shortly afterwards came rapidly into extensive general use. *

Previous to the introduction of the plan now generally adopted, coals were chiefly transferred by waggons from the various collieries to the river, where they were put into keels or barges, the bottom of the waggon being let out, and the coals running down a spout or guide to the keel; in these keels they were conveyed down the river to the vessels, and cast by the keelmen into the hold of the vessel.

From these various operations and transhipments the coals received much damage by breakage, and the attendant expense was also considerable. The same system is, however, in use in some collieries at the present day; but from the various railways now in progress, which will bring all the coal to parts of the rivers at which they can be shipped at once into the vessels, there is little doubt but that in a few years a keel will hardly be known upon either the river Tyne or Wear.

During the year 1837, the quantity of coals shipped from the north of England was as follows: from Newcastle 2,868,651 tons, Sunderland 1,174,598 tons, and from the port of Stockton 1,192,353 tons, making in the whole 5,235,602 tons; of which it may be calculated that at least three fourths are shipped by means of drops varying considerably in arrangement of the machinery, but all upon the principle of the original patent.

The advantages of the plan are, that it avoids considerable breakage to the coals, as the waggon is lowered down to the level of the deck of the vessel, and the coal has much less height to fall; that by arranging the length of the vibrating or falling frame according to the situation, a vessel may lie in deep water at a distance from the quay and receive her cargo; and that the whole machine being self acting, the expense of shipment is very trifling. * *

The cost of one of these drops, including all machinery, timber, and iron work, but exclusive of masonry and gangway, is about 500*l*. Great steadiness is given to the machinery by two heavy piers of masonry, the four main legs (upon which the whole of the superstructure rests) being half let into them, and firmly bolted together by strong bolts running through them.

The great length of the vibrating frames enables vessels to receive their cargoes at these staiths, whilst lying in a depth of water varying from thirteen to sixteen feet (at the different drops) at low water of a spring tide.

One of these drops is capable of shipping one Newcastle chaldron of coals of fifty-three cwt. every minute, but this is never required in practice, as the coals cannot be trimmed in the ships so fast, the usual work being from twenty-five to thirty-five chaldrons per hour.

Paper VIII. is *on the Principle and Construction of Railways of Continuous Bearing, by John Reynolds, A. Inst. C. E.* The author describes the advantages of his patent rail, and compares its cost with other rails; time and experiments, however, are the only tests of superiority. A length of the patent rail has been laid down on the Great Western Railway, but we have not yet heard whether the result of the experiment has proved successful or not.

Paper IX. describes a *Wooden Bridge over the River Calder at Merfield, Yorkshire, designed and erected by William Butt, A. Inst. C. E.* Simplicity and cheapness in the construction constitute its great recommendation. The span of the bridge is 147ft. 6in., and 11 feet rise; the roadway is 5 feet wide in the centre, and 8 feet at each end; its cost was under 500*l*.

Paper X. is *on the Teeth of Wheels, by Professor Willis.* The simplicity to which the professor has reduced the method of setting out the teeth of wheels will be both useful and valuable to the millwrights. We shall, very probably, be induced to examine this paper on some other opportunity; as, to do it justice, it would require more space and time than the lengthened extracts we have already given on other papers would enable us to spare.

Paper XI. contains *a Series of Experiments on the Strength of Cast Iron, by Francis Bramah, M. Inst. C. E.*, and describes a series of 29 experiments on cast iron, very carefully performed on various sections; the rectangular, the T form, the T reversed, the open rectangular, open T, and the triangular; the general length of the specimens was 3ft. 1in. in the clear of the bearings, and they weighed from 15 to 22 pounds each. The whole of the experiments made were very satisfactory, and fully proved the importance and value of Tredgold's formulæ. Mr. Bramah observes—

That the extent of the elastic power of the material is the limit of practical strength there can be no doubt, for as soon as the applied force exceeds that amount, the tenacity of the material becomes sensibly impaired, and the injury increases rapidly as the point of fracture is approached. The coincidence of the two forces, extension and compression, to produce equal effects when confined within the limit of elasticity is very striking, and their divergency after passing that point is equally remarkable. * *

It is a striking feature in these experiments, that the results not only accord most minutely with the theoretical deductions of Tredgold, but that they show most completely that the aggregation of the particles of the metal, whether in the smaller or enlarged sections, is nearly the same; since in beams of the largest kind weighing from four to five tons and upwards, and constructed to sustain a load of from 50 to 150 tons weight, the same degree of fidelity attends the comparison. It is very important to know this, for in work of such extensive requisition as Tredgold's essay on cast iron, to have a doubt existing of its accuracy in theoretical or practical detail is to involve the practitioner in the most painful perplexity. It is also a source of the highest gratification to be enabled upon this positive testimony to conduce so decidedly to the establishment of such a valuable contribution to science, and to maintain, although it cannot elevate, the character of a man who, by his peculiar acumen and indefatigable industry, has in the very limited period allotted to his scientific labours, enriched so many of the paths of science by eradicating the weeds of empiricism, and in their stead sowing the seeds of principle, founded on the natural laws and affections of matter.

Paper XII., *on certain Forms of Locomotive Engines, by Edward Woods,* advocates the adoption of six wheels for locomotive engines, and points out the several disadvantages of the old locomotive, which have been overcome by the addition of a third pair of wheels.

The advantages obtained were almost immediately apparent. The engine lost in a great degree its peculiar rocking motion, as also the unsteadiness arising from lateral undulations; which latter effect was in like manner attributable to the diminution of the angle of which the oscillations were susceptible. Beside such direct and immediate results, time soon developed further consequences of an important nature. The component parts of the engine remained for a much longer period than before securely united and firm, the fastenings of the tubes became less liable to leak and give way, and the bolts and stays of the framings were less disturbed. Lastly, though not of least importance, an inherent source of safety was superadded, in the diminished liability of the engine to run off the rails in the event of the large wheels or the crank axle breaking. Instances in which this quality has been put to the proof have occasionally occurred. They have invariably demonstrated the high importance of the application as an especial security to passengers and to the attendants; and in consequence the principle introduced was not abandoned, even after the road had been entirely relaid with new rails.

Paper XIII. is an *Account and Description of Youghal Bridge, designed by Alexander Nimmo, by John E. Jones, A. Inst. C. E.* There is nothing particularly attractive in this bridge, excepting its great length. Its construction does not possess any new feature.

Paper XIV. is *on the Evaporation of Water from Steam Boilers, by Josiah Parker, M. Inst. C. E.* This is a valuable paper, containing a practical examination into that important subject, the comparative quantity of fuel consumed for the evaporation of a given quantity of water; and we regret that we cannot now enter more fully into this important paper, as it is one deserving of the attentive study of every person interested in the employment of a steam engine, whether he be a manufacturer of them or merely a proprietor.

Paper XV. is an *Account of a Machine for cleaning and deepening small Rivers, in Use on the Little Stour River, Kent, by W. B. Hays, Grad. Inst. C. E.* Much good may be effected by collecting drawings and descriptions similar to the one described in this paper, for we feel convinced that many of them would be found admirably well adapted for the formation of harbour and the improvement of tide rivers. We cannot explain the operation of the machine described by Mr. Hay, except from the drawings, which we could not copy without trespassing on the original work. We should feel obliged if some of our correspondents would favour us with drawings and descriptions of similar machines, and the cost of constructing and working them.

Paper XVI., *Description of the Perpendicular Lifts for passing Boats from one Level of Canal to another, as erected on the Grand Western Canal, by James Green, M. Inst. C. E.* This is another useful practical paper, clearly and accurately describing the construction and working of the lock, and accompanied by some excellent drawings, very beautifully engraved; but it is useless for us to attempt to give any lengthened extract, as the whole of the paper and drawings are necessary to a proper understanding of the construction, and as we have given an outline of this communication in Journal No. 8, page 200, and No. 9, page 229.

Paper XVII., *on the Methods of illuminating Lighthouses, with a Description of a reciprocating Light, by J. T. Smith, Capt. Madras Engineers, &c.* In this paper is described the system of lighting by fixed and revolving lights, and afterwards the mechanical arrangement of the reciprocating light.

The whole of the reflectors are fixed in their proper positions to a reflector frame, attached to a central spindle placed vertically, and to which motion is communicated from a machine of common construction (moved by a weight and regulated by fans) by means of a couple of bevelled wheels, one of

which is fixed on the vertical spindle just mentioned, and hence revolves in a horizontal plane; the other turns in a plane at right angles to the above on a vertical plane, its arbor or axis being at right angles to the spindle. Now, if instead of this single vertical wheel, acting continually on one side of the horizontal one abovementioned, another one be similarly situated on its *opposite* side, and engaged in the teeth on its margin, these two wheels are mounted on the same arbor and consequently turn in the same direction, it will be evident that they would, if successively engaged, produced *opposite* motions in the spindle and the apparatus, but that if both were engaged at the same time no motion at all could be effected, since by their opposite tendencies they would *act against* each other.

This successive action, therefore, is effected by fixing both of the wheels upon the arbor in the same manner as if they were singly employed, that is, with their teeth engaged at the proper pitch in the horizontal wheel above them, and then by cutting away those of the alternate semi circumferences of either, so that while those are engaged and produce motion in one direction, the blank circumference of the other is presented, and the moment the former ceases to act, the teeth of the latter come into play, producing an opposite movement.

Paper XVIII. contains *Experiments on the Flow of Water through small Pipes, by W. A. Provis, M. Inst. C. E.*, an abstract of which will be found in Journal No. 14, page 383. We regret that Mr. Provis had not time to carry out his experiments to different sized pipes, both straight and curvilinear, and also to an examination into the best form of connecting pipes with reservoirs and cisterns; likewise connecting one pipe with another. We hope that he will be able to resume his experiments, and give their result in the ensuing session.

Paper XIX. *Experiments on the Power of Men, by Joshua Field, V. P. Inst. C. E., F.R.S.*

In this paper are recorded the results of some experiments made to ascertain the working power of men with winches, as applied to cranes. The experiments were undertaken with a view of ascertaining the effect men can produce working at machines or cranes for short periods, as compared with the effect which they produce working continuously.

The apparatus, a crane of rough construction in ordinary use, and not prepared in any manner for the experiments, consisted of two wheels of 92 and 41 cogs, and two pinions of 11 and 10 cogs; the diameter of the barrel, measuring to the centre of the chain, was 11¾ inches, and the diameter of the handle 36 inches. The ratio of the weight to the power on this combination is 105 to 1.

The weight was raised in all cases through 16½ feet, and so proportioned in the different experiments as to give a resistance against the hands of the men of 10, 15, 20, 25, 30, and 35lbs. *plus* the friction of the apparatus. * *

In order to compare these experiments with each other, these results must be reduced to a common standard of comparison, and it is very convenient to express the results of such experiments by the pounds raised one foot high in one minute, this being the method of estimating horses' power. The number is in each case obtained in the following manner. I will take the first experiment.

Here 1,050 lbs. was raised 16½ feet high in 90 seconds; this is equivalent to $(1{,}050 \times 16{\cdot}5) = 17{,}325$lbs. raised one foot high in 90 seconds, which is equivalent to $(17{,}325 \div 1{\cdot}5) = 11{,}550$lbs. raised one foot high in one minute. In this case then the man's power $= 11{,}550$.

The same calculations being pursued in the other cases, give the numbers constituting the last column of the following table:—

No. of Experiment.	Statical resistance at handle.	Weight raised.	Time in seconds.	Time in minutes.	Remarks.	Man's power.
I.	10	1050	90	1·5	Easily by a stout Englishman	11550
II.	15	1575	135	2·25	Tolerably easily by the same man	11505
III.	20	2100	120	2	Not easily by a sturdy Irishman	17325
IV.	25	2625	150	2·5	With difficulty by a stout Englishman	17329
V.	30	3150	150	2·5	With difficulty by a London man............	20790
VI.	35	3675	132	2·2	With the utmost difficulty by a tall Irishman	27562
VII.	..	....	150	2·5	With the utmost difficulty by a London man, same as Experiment V.	21255
VIII.	..	....	170	2·83	With extreme labour by a tall Irishman	21427
IX.	..	....	180	3	With very great exertion by a sturdy Irishman, same as Experiment III. ..	20212
X.	..	....	213	4·05	With the utmost exertions by a Welshman ..	15134
XI.	..	....	35	....	Given up at this time by an Irishman	.....

We may consider experiment IV. as giving a near approximation to the maximum power of a man for two minutes and a half; for in all the succeeding experiments the man was so exhausted as to be unable to let down the weight. The greatest effect produced was that in experiment VI. This, when the friction of the machine is taken into the account, is fully equal to a horse's power, or 33,000lbs. raised one foot high in one minute. Thus, it appears, that a very powerful man, exerting himself to the utmost for two minutes, comes up to the constant power of a horse, that is, the power which a horse can exert for eight hours per day.

Paper XX., *Particulars of the Construction of the Floating Bridge lately established across the Hamoaze, between Torpoint in the County of Cornwall, and Devonport in Devonshire, by James M. Rendell, M. Inst. C. E., &c., &c.* Although last, this communication is one of the most important. It describes an entirely new method of forming a communication from one side of a river to another. We have no doubt the publication of this paper will lead to a very extensive introduction of the floating bridge in all parts of the kingdom. Mr. Rendell has accompanied his paper with some beautiful drawings, explaining the construction of all parts of the vessel, the engine, &c. In Journal No. 7, page 169, will be found an abstract of this paper, to which we add the following particulars:—

The cost of the first bridge, with its machinery and chains, was 3,222*l.* that of the second was 3,316*l.* The cost of the landing planes, shafts, and balance weights, 1,530; of engineering and law expenses about 1,000*l.*; making the whole expenditure about 9,068*l.* The yearly charges of disbursements amount to 691*l.* 7s. 6d. * *

As yet we have no means of fixing with any precision the sum which should be reserved yearly as a rebuilding fund, for the bridges and machinery are still as good as new; and the chains, which at first I expected from the great depth of the river would be an expensive item in the repairs, are scarcely at all worn.

The income of the ferry for the year ending 11th April, 1834, when the bridge was opened to the public, was 930*l.*, whilst for the year now just ending, the tolls are let at 2,000*l.* over and above the cost of collecting, being an increase in four years of 1,070*l.*, that is, the tolls have already more than doubled. This is the strongest evidence than can be adduced in proof of the great accommodation which the bridge affords. * *

In conclusion, I have only further to state, that whilst the bridge here described was in construction, one was established at Saltash (higher up the Tamar), and still more recently, a similar bridge (though differing in the arrangement of its details to suit the locality) has been established under my directions at Southampton, across the Itchen, which is, at the site of the bridge, 1,400 feet wide at high water, and is crossed eight times an hour. This bridge is found so formidable a rival to the *fixed* bridge a little higher up the same river at Northham, as to have drawn off nearly all the travelling, the trifling saving in distance into the Portsmouth, &c., road which the floating bridge and new road effect, being sufficient to induce all the stage-coaches and mails, amounting to eleven a day, and general travelling, to use it in preference. This is the most convincing proof that the accommodation is regular and commodious. Already the tolls of this bridge have been let for 2,500*l.* per annum, although the work has not been finished eighteen months; and the only traffic on the ferry previously to the establishment of the bridge was foot passengers, and produced only 400*l.* a year.

We have now gone through the whole of the papers, and although our remarks and extracts are rather extended, we feel our inability to do full justice to many of the important papers, but must beg our readers to be satisfied with the view we have been able to afford them of this work, which exhibits much sound practical information and naval research.

Illustrations of the Public Buildings of London, with Historical and Descriptive Accounts of each Edifice. By Pugin and Britton. Second Edition, greatly enlarged, by W. H. Leeds, in 2 vols. London: Weale, 1838.

We regret that the late period at which we received this work prevents us from entering into a critical examination of its details, but as the former edition has been, for many years, before the profession, the general basis of the work must be sufficiently known to them to render this delay a matter of less importance. On the present occasion we must content ourselves with reminding our readers that it is a work of high sterling merit, and to assure them that this new edition, which was so much called for, is not behind in maintaining this high character.

It contains outline engravings of most of the public buildings of the metropolis, with geometrical plans of each building, executed with great neatness and exactitude. Among the many important additions are Buckingham Palace, the Post Office, the Corn Exchange, and the Traveller's Club. The letter press of the former edition has been revised, and augmented with many valuable critical notes, which confer great credit on the gentleman to whom the editorial department has been confided. In the preface, Mr. Leeds points out the important share which he has taken in the improvement of the work, and as this will best enable the reader to appreciate his task, and the value of the new edition, we consider that the following extract from the preface will prove acceptable:—

To many it has been matter not only of regret, but of surprise, that a work like the present, so convenient and economical in form, and interesting to others as well as professional men, should not have been continued beyond the two volumes originally published; more particularly as in the interim from their appearance, a variety of structures of more or less merit and note have been added to the public edifices of the metropolis. That there is an abundant supply of fresh subjects for such purpose, will hardly be disputed;

many of them, as it is hoped this new edition will satisfactorily testify, even more interesting than several of those previously represented. Yet although there are ample materials for a third or even a forth volume, the present publisher deems it more advisable, as the work is now out of print, to commence with an entirely new edition containing several hitherto unedited buildings.

Besides the additions both in regard to plates and their descriptions, others to a very considerable extent have been made by the present editor, both in the form of notes, and of remarks appended to the accompanying letter-press by other writers. The opinions of the latter have been left untouched by him, even when decidedly at variance with his own; in order that the reader may adopt whichever shall appear to him the most judicious, and the best-founded. All that has been done in the way of altering the original letter-press, has been confined to abridging several of the articles, by paring away what was evidently extraneous matter, what related only very remotely indeed to the buildings themselves, and was by no means in accordance with the character of a work that is most undisguisedly of a strictly architectural nature, therefore not at all likely to find purchasers among those who seek merely historical and topographical information.

One unquestionable improvement upon the first edition is, that instead of the subjects being mixed together, without any attempt at arrangement, they are now classified under the respective heads of, I. Churches; II. Theatres; III. Commercial and Civic Buildings; IV. Buildings connected with Literature and Art, &c.; V. Palaces and Private Mansions: VI. Bridges. * *

In addition to the general classification now adopted, chronological order has been in some degree observed, and the works of the same architect, when belonging to the same class (as Wren's churches), have been placed together. The third, fourth, and fifth divisions, are so miscellaneous as hardly to admit of precise arrangement, on which account the only order attempted in regard to the first-mentioned, is that of their situation in the course from east to west.

As every one of the buildings now added to the original subjects is of quite recent date, no history as yet attaches to them; a circumstance the editor is far from regretting, because the respective accounts are now necessarily confined to remarks on the buildings themselves; whereas, when History and Architecture sit down to make a meal together, the latter gets very little more than the crumbs which fall from the table, while poor Criticism is fairly kicked under it, as if unworthy even to show her face. In the preface to his *Geschichte der Kunst*, Winckelmann gives us an anecdote to the purpose, of a writer who filled what professed to be an account of two statues of captive barbarian kings, with a history of Numidia! * *

And architects ought by this time to have discovered, that the better informed the public in general are in respect to their art, so much the better both for that and for themselves. In proportion as architectural topics can be made to engage general attention, and rendered matter of conversation and discussion in society, so will the public take a livelier and more extended concern in the art. In this respect something has been done of late years by the establishment of the "Architectural Magazine," which there is every reason to suppose has been the means of leading many to direct their attention to a study which, if rationally pursued, is not without its allurements for others besides professional men.

More recently another periodical has appeared, entitled "The Civil Engineer and Architect's Journal," which, in conformity with its title, devotes itself more particularly to strictly technical and practical matters, yet by no means to the exclusion of more popular subjects. Both these publications have already effected some good in disseminating a taste for such studies, and in diffusing more enlarged and liberal views in respect to the æsthetic principles of architecture, than have hitherto prevailed.

How far the editor's own criticisms, here offered to the public, satisfactorily exemplify what he recommends, must be left to the reader to determine. At all events, they are in no very great danger of being found fault with on the score of not entering sufficiently into details, or of being too dry and formal. Leaving alone what may be thought of many of the opinions and remarks they contain, they will strike different persons very differently, because some will relish them all the better for that, on account of which others will probably object to them. The writer who attempts to accommodate himself to the particular taste of every one, will please no one; whereas he who satisfies himself, will at all events have the luck of pleasing some one, and be apt to write naturally, if not originally. * *

Should what has been done be found to give satisfaction, the editor will most probably resume his task, it being in contemplation to carry on the work by at least one additional volume; yet further than that probability is at present in favour of this being done, no assurance is here given—no positive promise made, because the performance of it will in a considerable degree depend upon the reception that shall be given to the two now published. * *

Even when all the available materials shall have been exhausted as regards the metropolis itself, there would still remain a new and ample stock for a similar—or companion work to the present one, illustrative of the Provincial Architecture of England.

As the field would be so extensive, such a work ought to be confined to the very best specimens, and to such as are unedited. The idea of a work of the above description, however, itself belongs to that species of architecture denominated "castle building," it being as yet matter of doubt whether the plan here hinted at will be acted upon. *

To speak, by way of conclusion, respecting his own share in the present volumes, it will be evident enough that the editor has not scrupled to impugn many *veteris mendacia famæ*, and to indulge in some observations that can hardly fail to shock what the author quoted on the title page calls the "orthodoxy of pedantry." Yet if not uniformly in accordance with those commonly received,—if they occasionally tread too sharply on the heels of prejudices,—if, moreover, some of them shall be convicted of being erroneous, as well as unpalatable, the opinions here put forth by him may at least claim the merit of being independent and unborrowed. He may also be allowed to say, that in the articles now added by himself, he has endeavoured, as far as the subjects themselves afforded scope for doing so, to invest description and criticism of this kind with some degree of interest, by impartially pointing out both merits and defects, and by calling attention to particulars, which, more frequently than not, are passed over altogether. If, therefore, in some instances praise and censure nearly balance each other, that circumstance argues no inconsistency in him, whatever it may do in respect to the buildings so spoken of.

The further examination of the work we must delay until next month, and in the meantime we earnestly recommend this work as a valuable addition to the libraries of the elder members of the profession, and an excellent guide for the studies of the younger.

Versailles: Heath's Picturesque Annual for 1839. Twenty highly-finished Engravings. Longman and Co.

If we have been greatly disappointed by the new volume of the "Landscape Annual," which exhibits a falling-off as sad as it is sudden from its predecessors for the last two or three years, both as to the subjects and the execution of its engravings, we are not a little agreeably surprised at the improvement manifested in this one of the "Picturesque." One very great and obvious improvement is the adoption of Hancock's patent binding, which will prove a most valuable invention indeed, if it can be applied to large architectural works and books of plates, since it causes the book to lie quite flat when open, whereas very great inconvenience is generally felt in the kind of works alluded to, inasmuch as they are quite curved towards the middle, so as frequently to render it almost impossible to take horizontal measurements with accuracy, on that side of an architectural engraving which is next the back of the book.

The "Picturesque" gives us this year several architectural subjects, and those too of a class which are of comparative rare occurrence, we mean interiors of galleries, and other splendid apartments. That such subjects should so very seldom be made choice of, is hardly owing to their want of interest—for we hardly know of any that are more so—but may very fairly be attributed to two circumstances; first, the difficulty of obtaining access to them, for the purpose of taking views; and secondly, the greater care and time required for the drawings, and afterwards the engravings. Here effect alone will not answer the purpose; in an exterior view, it seldom happens that there is occasion to show much of the minutiæ of details, because it seldom happens that any part of the building represented comes immediately into the foreground; but in interiors, all the details of foreground, whether those of walls, ceiling, pavement, or carpet, together with those of furniture, must be distinctly shown and expressed, let them be ever so intricate, complicate, and elaborate. Of what may be effected in such subjects, even within the compass of an octavo plate, we have here proof in those of the Chapel, the Grand Gallery, the Gallery of Statues, the Theatre, &c., in a palace remarkable for its lavish decorations though not exactly a model as regards the taste displayed in it. Most of these plates are from drawings by Mackenzie, whose admirable talents for similar subjects stands in need of no compliment from us; nor can we but wonder at the extraordinary diligence with which every piece of detail is elaborated. As an instance, we refer to the cornice and ceiling of the Gallery of Battles, also to the Great Gallery or that of Mirrors, so called from the arcades opposite to, and corresponding with the windows, being filled with plates of glass to resemble other windows.

We do not recollect having before met with any interiors of this class, so highly finished-up; for they have either been in imitation of coloured drawings, as those in Pyne's "Royal Residences," and Nash's "Brighton Pavilion," or else very different as to subject; for instance, the elaborately engraved interiors of Henry the Seventh's Chapel, in "Neale's Westminster Abbey," a work, by-the-by, that places that artist in the very highest rank of architectural draftsmen. With these specimens in the "Picturesque" before us, we cannot help being of opinion that there is a very extensive and almost untouched field of architectural illustration open to any one disposed to enter upon it. Numerous subjects, of equal or even greater pictorial interest, might be found without quitting our own metropolis; and a work illustrating them after the style of the engravings in this Annual, could hardly fail of success. Nor perhaps could any one be found fitter for such an undertaking than Mr. Heath. We hope he will take our well-intentioned hint, and thereby fill up the utter blank that at present exists in regard to one department, and certainly not the least unworthy one, of the graphic illustration of our architecture. Meanwhile we congratulate him on the improvement manifested in his "Picturesque Annual" this year, which we recommend to all our architectural friends;—not, however, for the letter-press portion, which might have been better, if instead of translating what

was furnished for the purpose by a Frenchman, Mr. Leitch Ritchie had availed himself directly of Zinkeisen's Historische Rückblicke on the Palace of Versailles, which is a most interesting historical and architectural memoir. Very probably, however, the letter-press will generally be considered of very secondary importance—at least such seems to be the case with most publications of this class; and if so, the engravings in the "Picturesque" this year give it a decided superiority over its rivals, and that not only on account of their intrinsic interest, but also the novelty of their subjects; whereas the picturesque of landscape scenery has of late been served up so often, as to be now quite hackneyed and stale.

---

1. *Geology of England and Wales, with a Map.* London: Grattan. 1838.
2. *Geological Map of England, Ireland, and Scotland.* By Professor Phillips. London: Weale. 1838.
3. *Geological Map of the British Isle.* London: Wyld. 1838.

These are some of the recent fruits of the progress of Geology in the public mind. The first is an elementary compilation with a small map, which presents two novel features; first, that the strata are represented by various modes of lineshading on the plate; and secondly, that it was originally published for threepence. The second is the first map of the whole of the British Isles, but being on a small scale admits but of little novelty in detail. The remaining work is an endeavour to render this class of maps cheap and easily accessible to the public.

Report to the "Académie Royale des Beaux-Arts de l'Institut," made in the Session of 1838, on the Work published at Milan in 1829, by M. Carlo Amati, *entitled "Dell' Architettura di Marco Vitruvio Pollione, libri dieci publicati di Carli Amati, Professore Architetto, membro di varie Academie, e della Commissione d'Ornato publico di Milano."* By M. Guenepin, Honorary and Corresponding Member of the Royal Institute of British Architects. [Translated from the French MSS.]

[As the subjoined paper excited considerable interest in France, we have availed ourselves of this opportunity to present a translation of it.]

The author of the work is M. Carlo Amati, architect, of Milan, for the last thirty-five years Professor to the Imperial Academy; Member of the Academy of Vicenza, and of many others; decorated with the order of St. Stanislaus of Russia; and lastly, Member of the Commission for the Public Embellishment of Milan.

M. Amati, who is architect of the cathedral of that town, has erected, according to his designs, a great number of buildings, both public and private; twenty-seven churches have been either built or repaired by him; and he is at this moment raising a Christian temple under the invocation of St. Charles Boromeo on the Corso de Servi at Milan, in place of the present church: the plans of which temple he has published in a volume, to be found in the library of the Institute; and on which one of our fellow-members will undertake the task of addressing you.

Notwithstanding such manifold and weighty occupations, and the unremitting attention that M. Amati has for many years paid to a number of scholars succeeding each other in his office, he has yet found leisure enough to publish several works relating to architecture, among which is a folio edition of the "Five Orders of Architecture," by Vignole, to which he has added some of the plans executed by that architect, a Treatise upon Shades, a work on the ancient Thermæ of St. Lawrence, at Milan, and, lastly an Italian edition of Vitruvius, in two volumes, illustrated by numerous well-engraved plates.

It is this work which is the object of the present review. M. Amati, full of love for his art, and of zeal for the instruction of his pupils, beheld them with regret deprived of the valuable assistance which they might have derived from the study of Vitruvius. In fact, there are but few editions in Italian of that author, for the most part very old, and only to be obtained with great difficulty. The important works published of late years on Vitruvius are little known in Italy; those of Rode, Schneider, Stratico, and Poleni are written in Latin, and can consequently only be understood by a few. M. Amati being desirous to remedy a want so prejudicial to the study of architecture, urged on by an irresistible desire of being useful to his profession, and encouraged, moreover, by the profound research he has bestowed upon the ancient monuments of Italy, did not hesitate to undertake an Italian translation of Vitruvius; an unthankful and laborious task, to which his modesty has allowed him to prefix the title of publication only. The terms which he has himself used in the preliminary notice of his work are remarkable for their simplicity and propriety; they deserve to be recorded word for word, and will explain, better than I can do, the utility of this undertaking and the able character of its author.

Having set forth some general considerations on architecture, M. Amati thus expresses himself:—"What Quintilian, speaking of eloquence, said of Cicero, may be applied to Vitruvius and architecture; that he who takes pleasure in the writings of Vitruvius will acknowledge himself to have profited not a little by the study thereof.

"Owing to the scarcity of the editions of Vitruvius, it has appeared to me to be necessary to publish a new one, convenient, cheap, and adapted to the capacity of that part of our youth who have devoted themselves to such an important profession.

"For many years I have directed all my cares and studies to this object, the utility of which is so considerable. Among the numerous editions that I have consulted, those of Durantino, Giocondo, Barbaro, and Schneider,—of Galiani, Orsini, and that of Stratico, and Poleni,—have chiefly served for the basis of this: I have merely added some short notes, rested upon the ancient monuments, or drawn from the commentators, in order to throw additional light upon the subject. The drawings follow the progressive order of the author's writings. I have annexed several from the most interesting works of Roman antiquity, for the most part examined on the spot, and measured by myself, and some others taken from the monumental remains of Greece, for the purpose of explaining and clearing up the true sense of Vitruvius' text. Each plate is accompanied with a succinct explanation of the principal proportions as they are to be found in the text itself. These plates are for the most part compiled from the original reading, and I have taken some from the illustrations of the most eminent commentators. Thus this edition will abound in nothing of mine, so much as the goodwill of being useful to those students of architecture, the instruction of whom has been for the last thirty years one of the most pleasing employments of my life."

It is not without some motive that I have rendered literally the words of our author; for they not only give a very complete idea of the end which he has proposed to himself, and of the path he has pursued, but they at the same time explain the wide difference that separates his publication on Vitruvius from the important editions of that author's works by Schneider, Stratico, and Poleni, and more recently, that of the Marquis Marini.

We must not expect, therefore, to find in M. Amati's edition all the enlargements, explanations, comments, dissertations, discussions, and other illustrations, with which the authors just named have, after the fashion of their predecessors, enriched their productions. In the simple *Notarelle* announced by M. Amati, as intended to render more intelligible the text, we have none of that ponderous baggage more voluminous even than the work; nor shall we meet there with any of those happy and unforeseen discoveries, or those luminous interpretations that present in a new light some of the many passages of Vitruvius which are yet but imperfectly explained, or which have been disfigured by commentators often more obscure than the author himself.

I could nevertheless quote a number of passages where M. Amati has in few words solved many serious difficulties which had often brought the reader to a stand; but the explanation alone of these difficulties, the discussions they would bring with them, and their enlargements, would far surpass the time placed at my disposal.

M. Amati has certainly done signal service to the art he professes with so much distinction, by giving to his countrymen in their own language an edition of Vitruvius, containing the result, and, in some sort, the summary of the labours and inquiries which have occupied so many architects and learned men since the revival of letters. By means of this work, the fruit of many years' experience, the student will avoid those investigations, always dry and tedious, and often inaccessible to the novice in architecture. The help of his profound erudition and long practice has alone enabled him to present to them in abridgement, if I may so express myself, the instruction which those who deliver themselves up to the pursuit of this science could not have obtained otherwise than by an assiduous and lengthened labour. We understand what care and perseverance it must have cost to have annihilated even the traces of the trouble an undertaking of this description must have involved.

If, then, M. Amati's work is not of those which open a new road to the interpretation of Vitruvius' text, or remove the boundaries of art, still it will possess the no mean advantage of increasing the circle of those who cultivate it, and of extending the taste for architecture, by rendering more attainable the means of its study. At this time, when the applications of art become daily more frequent, there is a happy *apropos* in placing within the reach of a greater number the acquisition of that information it imperatively requires.

Everything, then, that is important to be known in those editions which have been published down to the present day, will be found in this of M. Amati; with the sole exception of the magnificent Latin edition, in four folio volumes, published at Rome, in 1836, by the Marquis Manni, from a press established on purpose by the author;

an immense and splendid work, to which he has dedicated many years of his life, and which he has enriched with one hundred and forty engravings, and all the documents that he considered necessary to make it complete.

M. Amati has signified his intention of publishing, for the use of those who may wish to read the works of Vitruvius in the original, the Latin text of that author, in a single volume, with the various readings, faithfully selected from the learned edition of Udini.

In spite of all that has been said and written of Vitruvius, it is impossible to speak of his works without noticing the author; and we cannot abstain from remarking, that something extraordinary seems to attach itself both to his person and to his productions. Vitruvius himself is but imperfectly known; it has not yet been decided whether he was really an architect, or simply an amateur, as may be inferred from several passages in his book. There is nothing certain as to the time in which he lived; his name and his country have been the objects of endless discussions, which have arrived at no definitive result; and now it is asserted that he never existed.

In Germany, where the wildest paradoxes are sometimes maintained with an earnestness that proves conviction, and sometimes with a boldness that carries weight, it has been asserted that Vitruvius was but an imaginary being.

In the work entitled "Rhenish Philological Museum" (Rheinisches Musæum fur Philologie), there is to be seen a correspondence which took place between Goëthe and Dr. Schultz, in 1829. No one will be astonished to see Goëthe, a poet, and almost universally skilled in literature, engaged in an architectural discussion, whilst, at another Academy of the Institute, are proclaimed his discoveries in botany and comparative anatomy. (Session of the Academy of Sciences of the 12th March, 1838.)

Dr. Schultz, a very learned man withal, and whose reputation in this respect is incontestable, affirms that the work of Vitruvius is a compilation of the tenth century, made by Sylvester the Second, who had been Archbishop of Rheims before he was made pope, and when, under the name of Gerbert, he was as yet but Abbot of Robbio. The basis of this work might have been borrowed partly from evidences collected from the Greeks and Romans, and partly from Arabic fragments; but the primary origin of the compilation would be due to a similar work in Greek of the fifth century. Dr. Schultz moreover intimates, that it might have been dedicated at that epoch to Otho the Second, or perhaps later, to Otho the Third.

Goëthe appears to have entertained with him this opinion, if we refer to what he says on this subject in his complete works (vol. xxiv., p. 142, and vol. xxvii., p. 191). With these many learned men of Bonn, Francfort, and elsewhere also agree—Messrs. Osarin, of Giesen, Welcker, Professor at Bonn, and Weber, of Francfort.

Dr. Schultz, above all, rests upon the little concord existing between Frontinus and Pliny, on the one hand, and Vitruvius on the other, concerning aqueducts, and the inclinations on which it is proper to construct them. In the Roman works of the Augustan age, according to Vitruvius, in the sixth chapter of the eighth book, it was usual to give the subterranean ducts an inclination of one or two inches in 100 feet; but above ground, and more especially in aquaducts, the inclination was still less. A fall too rapid would have had the inconvenience of leaving the pipes dry, and of supplying troubled and muddy water.*

The maximum inclination pointed out by Vitruvius does not equal the minimum employed by the Romans even in their mock-naval fights, where the pipes were subterranean, and consequently more exposed to resistance, and in which it was less important to obtain the water limpid and clear, than to fill immense spaces in a short time.

Several other discrepancies between the doctrines of Vitruvius, and what is related by Pliny, Frontinus Mechanicus, Atheneus, the compiler of Alexandria, and other authors, have served Dr. Schultz for a basis on which to found his assertions. I refer to his correspondence with Goëthe, to explain the texts upon which he relies. I could not here dwell upon them without swelling beyond measure a report already too long; perhaps, indeed, I have insisted too much on an opinion so whimsical as to appear to belong rather to the history of the human mind than to that of architecture.

The work of Vitruvius has not been more free from the vicissitudes of opinion than his person—for books as well as men have their fate. At the revival of literature it was welcomed with the blindest enthusiasm, its precepts were recognised as infallible, and its author was for a long time regarded as the supreme law-giver in architecture; but when a vigorous investigation of the text had exposed a number of unintelligible passages, the obscurity of which, no doubt, arose from the absence of explanatory plates not to be found with the manuscripts, and still more when the assiduous researches on the monumental antiquities every where coming to light, had shown that, in many instances, the doctrine of Vitruvius did not tally with those beautiful models bequeathed to us by the ancients; the implicit faith our author had inspired was replaced by a more considerate and qualified admiration. And it was understood how a profound and attentive study of this work, united with that of the monumental remains, might illumine, and perhaps establish the theory of architecture.

These studies, continued with perseverance up to the present time, far from being barren, have borne abundant fruits; a great number of obscure passages have been explained, and everything inclines us to the belief that notwithstanding the success that has hitherto crowned the labours of art and erudition, of which Vitruvius is the object, much may yet be done. The study of the Grecian monuments, disentangled and simplified, may lead us to hope that the lost drawings of Vitruvius's work may be recovered from the ruins of the monuments he has cited. Already some valuable remains of edifices mentioned by him have been recognised, and though the much desired time for rightly interpreting the text of Vitruvius does not appear to me to be yet arrived, it cannot be far distant.

It is not at all certain whether Vitruvius had ever travelled out of Italy, though the monuments of Asia Minor are those he cites most willingly; he does not seem to have attached much importance to, or perhaps he was but imperfectly acquainted with, those of Attica and Greece. He even goes so far as to advance, in the third chapter of his second book, a remarkable opinion that I shall quote from the translation of Perrault:—"There have been certain ancient architects who did not conceive the Doric order to be fit for temples, as there was something inconvenient and embarrassing in its proportions. Farchesius and Pytheus were of this opinion, and it is also said that Hermogenes having a great quantity of marble for constructing a Doric temple to Bacchus, changed his plan, and made it Ionic. (Nonnulli antiqui architecti negaverunt Dorico genere ædes sacras oportere fieri, &c.)

It is probable that these Doric temples of Greece, of Sicily, and even those of great Greece, although situated in Italy, were almost entirely unknown to him.

It is also probable that to the study of the ancient monuments of Attica, and the other parts of Greece, at this moment followed up with so much activity, will succeed that of the antiquities of Asia Minor; then the comparison which may be made between the edifices cited by Vitruvius, and his own work will, perhaps, explain the difficult passages of the text, in the same way that those parts of the monuments which may need interpretation will be explained by him.

This work will thus become more valuable; it ought then always to be considered, and deservedly so, as one of the most precious that antiquity has transmitted to us. In it will be found a new source of information, curious remarks which could not be met with elsewhere, and details full of interest on the state of the arts and sciences among the ancients. The greatest benefit will fall to the share of the student, and it will be allowable for every one who has read it to boast that he has done so, and above all that he has understood it.

* According to the same Dr. Schultz, Pomponius Mela is likewise a supposititious writer; the work entitled "De Situ Orbis," is a youthful production of Boccacio, the author of "Decameron," who might have availed himself of the fragment bearing the same title of the ninth or tenth century, and deposited at Mount Cassino.

ORIGINAL PAPERS, COMMUNICATIONS, &c.

RALPH REDIVIVUS—No. 11.

THE CITY CLUBHOUSE.

This is certainly the handsomest clubhouse in the City, for the simple reason that it is at present the only one, therefore has nothing to apprehend from comparison with any rival in the same quarter. Similar, however, as it is in its style and general design to one or two at the other end of the town, it is as far remote from them in taste as is east from west,—which, perhaps, the reader will say, is no more than right and proper, considering the respective localities. Yet how, it will—with another *perhaps*—be asked, if it is cognate with them in style, can it be so foreign from them in taste? For the very simple reason that the style itself is treated without taste.

Of late years there has been a vast deal of prosing and twaddling about styles of architecture, to very little actual purpose; for after all that is said, it is of infinitely more moment how the style is treated than what it is; because the very best style may be rendered feeble

and trashy, tasteless and insipid, by bad management of it, and an inferior one imbued with elegance and spirit by a mind capable of entering into it with *geniality*—that is, a mind capable of infusing fresh vitality into its elements. Now, although mixed with a great deal of rubbish and dross, the elements of Italian architecture are so complex and varied, that if well filtered from their impurities, and a little of spir. gen.—which must not be mistaken gin—be added to them, they are almost all-sufficient for any occasion. The misfortune is, that the same spir. gen. is not a marketable commodity—is not to be had for money, nor to be procured at any dispensary whatever; accordingly, it is mostly dispensed with altogether, and those who have it not, get on as well as they can without it, or contrive, perhaps, to make the world believe that they possess of it at least *quantum sat.* All this, however, is merely proem—the printer, I hope, will blunder it into poem. But *revenons* in good earnest: the building in question is stamped, I will not say by all the defects of the style, neither by its worst vices, but by its most tolerable faults, without any of its redeeming qualities. There is nothing particularly to offend, so also is there nothing whatever to admire. Its worth as a design is altogether negative, for it has that *je ne sois quoi* of badness which it is as impossible to define as it is the correspondent quality in regard to beauty. Without being particularly ugly, it is more than particularly inelegant. Without presenting any very glaring solecism it is mawkishly mediocre, and exquisitely dull *secundum artem.* There is little in this façade which, taken by itself, can be censured as decidedly bad—at least not as at all worse than may be observed in many other buildings that possess some degree of merit; but everything about it is poor, has an awkward, plodding air, and bespeaks utter apathy of taste. There is, if may I be allowed the expression, the mere *surface* of the style, just enough of it by which to recognise it, without anything to give assurance that the architect himself has any relish whatever for it, or knows it otherwise than as a schoolboy has got his lessons. The remark just made applies unfortunately not to this building, but to many others—to a very large proportion indeed of our modern *soi-disant* Grecian and Gothic, which too evidently betray that those who designed them have but very little kindred feeling for, and but very imperfectly understand, the resources of the respective styles. To which remark I may further tack, by way of *codicil*, that architects are too apt to complain, and lay the fault upon circumstances; when the deficiency rests mainly, if not entirely, with themselves. Undoubtedly it much more frequently than not happens, that an architect is fettered and cramped, not merely by considerations of economy, but also by whims and caprices of others, and prevented from following out his ideas; yet let him be ever so much cramped that way, he is not, therefore, hindered from accommodating his ideas to circumstances; and thus debarred from proceeding, as he probably might do, according to some approved precedent, he is still left to the resources of his own mind, provided he has any, together with those of his art;—in one word, to show his feeling and his originality. Merely to do well what a hundred others could perhaps in the same situation do *quite as well*, is no very particular achievement; but to possess such a mastery over the elements of beauty as to hold them at beck, and compel them to diffuse a secret grace over the most unpromising subject—to do that—to ennoble what in other hands would sink into utter insignificance, if not into positive hideousness, is far worthier than it would be to erect a second Parthenon. However confined and cramped he may be, a man of genius will never betray it, because he will take care not to let it be seen that he has aimed at one tittle more than he has been able to accomplish.

Encore, revenons. I was saying that the architect of the City Clubhouse seems to have very little real feeling for the style he has adopted; because, instead of availing himself of one of its best characteristics, he has substituted for it what, while it reminds us of it, makes us feel its great inferiority. I allude to the insipid horizontal stripes on the piers between the windows of the lower floor, thereby giving his basement an air of finical neatness and spruceness quite at variance with the formal taste elsewhere displayed, and more especially with the grotesquely cumbrous richness of the trusses and festoons to the doorway. Here, then, we behold in juxtaposition two most incongruous specimens of architectural costume, and though there may be some novelty in putting them thus fancifully together, there is assuredly very little originality, or rather quite the reverse of it. Had this doorway been rendered obviously the principal feature in the composition, and the rest treated as altogether secondary, then it might have been even still more ornamented, without appearing at all too much so. Even had the *outré* fashion of decoration here set been consistently followed, and expanded throughout, there would, at all events, have been unity, and the partial heaviness now so observable would have been avoided. Where uniformly adhered to, even heaviness may be a merit rather than not; for it is conflicting expressions, which must by no means be confounded with *contrasts*, that are injurious in architecture.

If, too, this doorway, so overcharged with fantastic ornament—that is, with ornaments which appear quite fantastic in comparison with the design generally—does not at all agree with the other parts of the basement, it is not much better in accordance with the exceedingly stiff and dry details of the upper part, where the Doric pilasters just serve to produce a certain cold formality and littleness, and where the dressings to the windows have a miserably meagre look. Infinitely better would it have been had the architect omitted pilasters, and decorated the whole front with bossages or rustics of different kinds, those below being more boldly expressed than those of the upper floor. That he did not adapt this is the more to be regretted, because we have no such example of the Italian style, notwithstanding that it affords so much scope for design, and is compatible with a very high decoration in the windows.

The fact is, even those who affect to admire and extol the Italian style appear hardly to understand what it is capable of, or to comprehend by it more than its most commonplace and uninteresting elements, without regard to those richer and more delicate qualities, of which the façades of the Travellers' Clubhouse afford two such beautiful examples, and upon the least of whose details more study probably was bestowed than was upon the whole design for the Clubhouse in Broad-street, unless it be that instinctive taste supplied the place of studious consideration. I am inclined to imagine that far less depends upon the style chosen, and far more upon the treatment of it, than persons in general seem to suspect; for while the very best may, as we daily see, sink down, not only to mediocrity, but to drivelling dullness and imbecility, so may the very poorest acquire a power and charm when taken up with geniality, and touched *con spirito, con gusto, con amore.*

DUTCH ARCHITECTURE.

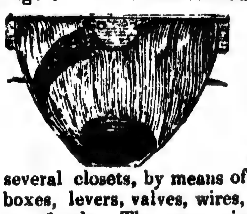
[The following extract from a letter written by a foreign architect, one of the corresponding members of the Institute of British Architects, to his friend, an English architect, conveys so just and striking an opinion of the architecture of Holland, that we doubt not it will be acceptable to our readers :—]

As you are acquainted with the town of Rotterdam, I have nothing new to tell you about it. I shall only add, that it perfectly brings to one's recollection the thousand views of Dutch towns to be met with in different picture-galleries; it does not, however, answer to the ideas of cleanliness which one forms respecting this singular country, and which, in the midst of a general movement, remains, to all outward appearance, in precisely the same state in which it was a hundred years ago. From Rotterdam, I went to the Hague: its general character differs but little from the Dutch towns; the country, however, is more agreeable, and the monotonous plain which pursues one in Holland, is partly hidden by a wood that surrounds a part of the town, and in which is situated a pavilion of the King, remarkable for nothing but its extreme simplicity; a large central hall, on account of its size, and the paintings it contains of the great masters, forms a distinct feature among the objects by which it is surrounded. I was much astonished at the Hague, by the extraordinary phenomenon of their executing *two new buildings at the same time;* it must have been a long, long time since a similar event occurred. One of the buildings, with a portico of columns, is intended for a sort of concert room; the other is a villa on the border of the wood; the general style of architecture of both evidences a good design, at the same time that it betrays a weakness in the carrying out, arising from want of study. You are aware that this town contains a rich and unique collection of interesting objects of all kinds, from China and Japan. I went over it with pleasure, and many objects connected with architecture and interior decorations interested me very much by their originality, and the good sense which they evidenced. This good sense—precious as it is—is becoming daily more rare amongst us: in saying *us*, I mean artists in general. From the Hague I made an excursion to Leyden, whilst I was waiting for the minister of Würthemburg (to whom I had an introduction) to prepare my letters for Amsterdam. I confess that I was infinitely better pleased with Leyden than with any thing I had before seen in Holland. I did not indeed find a better style of architecture, nor superior scenery; but the cleanliness and breadth of the streets, the well kept canals, and the quiet which reigns there, so consistent with the existence of an university, produced a very agreeable impression upon my mind. I visited the botanical gardens and hothouses, but found them nothing in comparison with what I had seen in England. To satisfy my conscience I

ran through the rooms containing the immense collection of natural history, and took a hasty glance at the skeletons and mummies, hoping to feast my eyes by the sight of the collection of birds and butterflies, for which I have quite a passion, on account of the elegance, the variety, and the brilliancy of form and colour, which nature has lavished upon these creatures; I was, however, disappointed, for these classes were not yet arranged, and the rooms were closed. I went to see the monkies, toads, bats, and other objects of this kind, which do not please the imagination of an artist, even whilst they are living; and which are repulsive when seen under glass, or in spirits of wine. As regards buildings I can only cite the Hotel de Ville, the exterior of which, though somewhat whimsical, has a certain piquant air, and bears the impress of Dutch architecture of the sixteenth century. After Leyden I proceeded to Amsterdam—with its pestilential canals, painted houses, and, for the most part, dirty streets, I searched in vain through this large city for a single building, which might please and satisfy an architect. The most common-place taste, mixed up with old-fashioned details, and an insignificant puerile and sterile invention pervade everything here. Even the Hotel de Ville, which is converted into a palace for the King, although of very vast dimensions is not grand, and only serves to prove, that even with immense sums of money a people without imagination and without refined sentiment must remain sterile and dry in their productions. I did not regret leaving Amsterdam for the pretty little town of Haarlem, which contains more than one edifice curious for its antiquity—there is one large church paved with wood, the walls very white and bare, copper lustres very bright, and an organ celebrated for the richness of its tone and the variety of its pipes. The environs of Haarlem present a long series of gardens and country houses of a bad style of architecture, such as I had observed throughout Holland.

ROE'S PATENT WATER CLOSET BASIN.

We noticed Mr. Roe's improvement on water closets when he exhibited one at the Architectural Society last session, and gave a drawing of the basin and a description, in Journal No. 6, page 141; since which Mr. Roe has considerably amended and simplified their mechanism, and has fitted up several under the directions of Mr. Hardwick at the Marylebone school, also for Mr. Wyatt and other architects. He is likewise about to supply a large number of them for the new hotels and dormitories now erecting at the Birmingham Railway Terminus, Euston-square. The principal improvement is in the basin, the edge of which is surrounded with a small chamber or recess, as shown in the annexed engraving.



This chamber is always kept charged with water, and when the handle is lifted, the water is discharged all round the basin, as well as the fan at the back, thoroughly and momentarily cleansing the pan. Another advantage of this addition to the basin is, that it saves the expense of a water or service box in the bottom of the cistern; and that the water may be laid on to several closets, by means of one pipe, instead of having distinct pipes, water boxes, levers, valves, wires, and cranks to each, which are continually getting out of order. The communication from the pipe to the basin is shut off by a stop cock, which is turned off and on by simply pulling up the handle of the closet in the ordinary way; and when the hand leaves go, it is immediately pulled down by the weight below, and shuts off the water, thereby preventing any waste. Although this arrangement is not new, we mention it, as Mr. Roe has obviated one great inconvenience in the cock, by making the key fit with great accuracy, and introducing an oil cup over the water way, which is always charged with oil, and constantly lubricating the key to prevent it setting fast or grinding, thereby avoiding leakage.

We are decidedly advocates for abandoning all the superfluities of the water-closet, and substituting, instead of the complicated apparatus of the valve, lever, water box, air and wire pipe, service box, wires and cranks, simply one pipe, with branches to each closet, as is effected by Mr. Roe. If the pipes be covered with a non-conducter of heat or cold, as hemp or wool, (as ought to be done with all pipes exposed to the weather,) there will be no fear of their bursting in frosty weather. If it should still be the wish to pursue the old plan of having a valve and the usual apparatus, the same may be used without having the water box. The Patentee, at No. 69, Strand, will be able to afford every illustration as to detail to any member of the profession.

MOMENTUM OF FALLING BODIES.

SIR,—It would be rendering an essential service to many of your readers if some of your professional correspondents would give some information as to the effective blow of the ram used in driving piles.

We all know that the effective blow of a body in motion is its momentum; and also that the momentum is measured by the weight multiplied into its velocity. A second being the shortest space of time which we can easily measure, the velocity acquired by a body in that time, falling from a state of rest, has been ascertained; and as the accelerated velocity is governed by known laws, the velocity, or rather the number of feet passed through, in a second of time, has become the datum of all calculations regarding the momentum of bodies. The rule therefore given to ascertain the momentum, is to multiply the weight of a body by its velocity *in feet per second.*

This rule is doubtless correct in a comparative estimate of the momenta of different bodies in motion; but I do not know that the rule would hold good in comparing a body in motion with one at rest. That is to say, that a body of the weight of 5lb., moving at a velocity of 16 feet per second, would produce the same effect as one of 80lb. at rest. There are, doubtless, a time and space which would be the exact measure of the effect produced in weight; but whether that is the velocity in feet per $\frac{1}{2}$, 1, or 2 seconds, nothing but a set of well-directed experiments can determine.

I have carefully examined several mathematical works in order to ascertain this point, but have been disappointed; and not being able to discover any reason why the number of feet, passed through in a second of time, should measure the effective momentum, any more than the number of yards, or inches, I should be obliged if some of your more enlightened correspondents would give us some information on this subject; or if the results of any experiments on the subject have been published, would direct us where they are to be found.

The subject, you will perceive, is one of considerable importance, as the stability of all bridges and buildings, erected upon piles as a foundation, depend upon it. The practical result to which I wish to arrive being to ascertain what weight, in a state of rest would produce the same effect as a ram of known weight falling on a pile at a certain velocity.

Hoping the subject may be deemed worthy the attention of some scientific correspondent, I remain, yours, &c.

November 13th, 1838. C. E. C.

THE NELSON MONUMENT.

The chief symptom of this project's exciting any interest among architects is that a plan of the site has been published for their assistance. Nevertheless it is a matter that ought to be timely attended to; and instead of holding back their remarks, as generally happens until the time for profiting by them has quite passed away, those who are, or fancy themselves capable of offering sound advice, should not delay it until it becomes little better than annoying, mischief-making impertinence. We have had quite enough of that mode of giving counsel in the affair of the new houses of Parliament, when, for some time after every thing had been settled, certain busy-bodies put forth pamphlets protesting against the style of architecture adopted and the site of the edifice; therefore, if intended to be of any use, the objections ought to have been made beforehand, and while there was opportunity for adopting them, without undoing and unsettling everything, and beginning, in fact, entirely *de novo*. Their excuse must be that they were conscious it would make very little difference at what time their advice was offered; and they could, besides, at any rate fancy that it would have been acted upon had it been forthcoming earlier.

In regard to the competition for the Nelson Monument, there is one thing that looks like extreme liberality, namely, that no restrictions nor conditions of any kind are imposed, further than that the cost shall not exceed 30,000*l*. The competitors are allowed, in fact, to choose their own subject—column, arch, or whatever other form they may devise for the purpose. Yet if thus far quite unfettered, I cannot help being of opinion that they must also be proportionably perplexed; because, under such circumstances, every one must be afraid lest his own idea should happen to be the only one of the kind, and therefore be deemed at once an 'out-of-the-way' one. On the other hand the perplexity of the committee is likely to be not at all less, when they come to sit in judgment upon, and have to make their selection from among a number of designs of so various a kind as hardly to admit of comparison. For this very reason alone it is highly desirable that there should be a public exhibition of the designs *before* any one be selected, in order that public opinion may be in some degree sounded, as to the kind of structure that ought to be adopted, and to elicit opinions from all sides. If perfect fairness, without anything approaching to trickery or delusion, be intended, surely such publicity ought rather to be courted than shunned; while, if it produced no other advantage, it would operate beneficially, first by giving an additional stimulus to men of talent, as they would be aware that if they displayed superior ability the merit of their designs could not fail to attract the notice of competent judges among the public, though it might fail to secure for them their main object; and secondly, by deterring many from entering the lists who must be conscious that theirs were ill-calculated to stand the test of a public scrutiny. Adverting once more to the embarrassment which, I think, it will be found the committee have subjected both themselves and the competitors, I must remark, that if the latter are left perfectly unfettered, they are at the same time left without anything whatever to guide them. Their designs may be for a temple, or a cenotaph, or a fountain, or a triumphal arch, or a column, or for a mere pedestal and statue upon it; or, in short, such is the latitude given for any ornamental structure, or display of sculpture, which will probably occasion many an old drawing of the kind to be dragged forth from its portfolio, and furbished up anew to serve as a Nelson Monument.

One thing, which most especially deserves to be considered, is the utter inadequacy of the sum to which the estimate is limited, for anything upon a grand scale, for any splendid array of sculpture and architecture. Either the monument must be very moderate as to size, or almost bare of decoration. The site naturally suggests a spreading substructure or platform, in some degree proportioned to the area in which the monument is to be erected;

but terraces with flights of steps, and ornamented parapets and pedestals, would swallow up nearly the whole funds, which being the case, I would suggest that it would be more prudent, on the part of the committee, to look, not so much to what can be effected at once with their present funds, as to what may be ultimately produced. Were a truly noble work commenced, one worthy of being considered a grand national trophy, I am inclined to believe that the public would come forward liberally with their contributions towards its completion; or, supposing that they niggardly refused to take a single farthing more out of their pockets for the purpose, I, for one, would much rather behold a magnificent plan to be left incomplete for another half century, than one on an inferior scale, and perhaps a decided failure, though fully terminated according to its design. The subject at least deserves to be most maturely considered by all who have our national credit in architecture at heart.

PRO CIVIBUS.

ARCHITECTURAL DICTIONARY.

Sir,—In the last number of your Magazine is a brief review of the Architectural Dictionary lately published under the editorial skill of Mr. Britton.

I am unwilling to trespass on your pages by any remarks which may appear suggested in the spirit of hypercriticism, or to make observations calculated to deter men of talent from offering to the profession the result of their researches, when such publication can reflect credit on the author, and confer benefit on the practitioner and student; but I must protest against the practice of book making instead of book writing, which certainly prevails at the present day, and it is in this spirit that I am induced to make my comments upon Mr. Britton's Architectural Dictionary.

I readily concede to Mr. Britton the credit of having *directed* many useful works, but this must not serve as a panoply to protect him when he undertakes a book professing to supply specific information, and either fails or neglects to fulfil this pledge.

A very palpable instance of this kind is evident in the Architectural Dictionary, a publication designedly brought forward to supply the deficiencies of former books of the kind.

You have already alluded to a few inexcusable omissions, and it is not difficult to prove a vast many others—a negligence the more remarkable, as Mr. B. seldom fails, in his prospectuses and prefaces, to relate the exertions and fatigues, with other personal matters to which he is subjected in compiling his books. It is certainly very doubtful whether any author ever equally exerted himself, or met with the like obstacles in his career, at least their prefaces have the good taste of being silent on such personal topics, leaving the volume of subject matter to testify what great toil and trouble must have been exerted by the compiler.

But I go to the work itself, which professes to supply the deficiencies of former Architectural Dictionaries,—*the inducement* that naturally leads those in possession of Stuart's Dictionary, Pugin's Works, with Willson's Glossary, and other recent glossaries, to possess themselves of Mr. Britton's book. As a student, I was desirous of making myself acquainted thoroughly with ancient terms now in frequent use, but I sought in vain for the following words under their initials:—Arras, Abbatoir, Badge, Blazoning, Battering, Bronze, Camber, Cramp, Cistern head, Cinque cento, Close, Discharging-arch, Dubbing, Flint-work, Filigree, Fleur-de-lis, Garth, Gussett, Guard-chamber, Handle, Husk, Linen-pattern, Lazar-house, Muniment-room, Medallion, Mask, Motto, Perforations, Pomegranate, Quartering, Ruby, Renaissance, Strawberry-leaf, Story-post, Stud-work, Scarfing, Saddle-bar, Wreath, Water-pipe. To these I could add many others, but I think the few mentioned come entirely within the province of an architectural dictionary; it cannot be said that they are insignificant in their meaning, and, therefore, unworthy of insertion, for this argument must exclude from the work many terms which are carefully explained.

It is readily granted that a complete dictionary of architectural terms is a difficult object to effect, but the classification under different heads, as you suggest, seems to offer the greatest probability of success, a scheme which would embrace not only ancient architecture, but the mechanical and other improvements of our own age, which require much exposition, since the application of science to purposes and objects not contemplated by our gifted ancestors has brought into action several classes of artificers, where formerly the mason and carpenter alone would have been engaged; and it should be the object of an architectural dictionary, of the nineteenth century, to furnish the professor and student with the peculiar technical terms used by each of these branches. Trusting that the day is not far distant when this desirable object will be undertaken by some competent person,

I remain, Sir, your obedient servant,

A CONSTANT READER.

[Several of these remarks had suggested themselves to us, but on recurring to one of the titles attached to the book, which styled it "A Dictionary of the Ancient Architecture of Great Britain," we did not feel ourselves justified in blaming Mr. Britton for his omission of articles relating to foreign medieval Architecture.]—Editor.

ON THE ARCHITECTURAL SOCIETY.

Sir,—As those who commit mischief are in duty bound to make all the reparation in their power, I hope that as you have narrated the vain squabbles of a T Square and a *Straight-edge*, you will not refuse to insert the peaceful exhortations of a *Set-square*.

T *Square*, then, should be first reproved, inasmuch as he gave the first provocation, viz., by stating, notwithstanding the secession of several of its members, among whom were Messrs. Wyatt, Walker, G. Moore, Owen Jones (the distinguished author of "La Alhambra"), Duesbury, and Ferrey*, that "the Architectural Society was still composed of those gentlemen who ever took its interests in their consideration, and supported it by their exertions, abilities, and funds," thus implying that the above gentlemen were mere cypers in the institution. His expression was a hasty one, and certainly an injudicious, if not an unjust one: for by provoking the calumniating reply of *Straight-edge*, the public trust and attachment to the society must be necessarily weakened. *Straight-edge*, however, should be treated with more marked displeasure, as his observations proceed from one who was formerly a member of the Society; otherwise, who could reckon themselves secure, when their nearest friends may, at a future time, become their deadliest enemies? He asks, in reply to T *Square*, "whether talent, or zeal, or liberality, or whether the circumstance of being amongst its earliest adherents, constitute the title to chieftaincy." Thus the injudicious remark of T *Square* is answered by *Straight-edge*, in words of even greater injustice and untruth. But *Straight-edge* is not satisfied here, but he next exhibits rancour and malice, in lieu of what should have been merely the feelings of a just resentment. After increasing the numerical strength of the seceding members, he goes on to state that "the numbers of the Architectural Society have decreased, and apathy usurped the place of that energy and spirit which was her strong ground." So far from this being the case, the list of members of the society is longer than it has ever been, and its resources in a more flourishing condition; so that they think of enlarging their rooms, and this even before the handsome presents to the society of 30l. from Mr. Tite, and 20l. from Mr. George Smith. The names of these gentlemen, with Messrs. I'Anson and Savage, were formally announced as having joined the Society on November 6, their first evening conversazione, notwithstanding his attempted intimidation.

He lastly endeavours to dissuade the public, "that ours is the profession of all others which possesses sufficient power and influence and is strong enough in the number of its followers, to admit of two societies being advantageously carried on." To this the rooms of each society bear sufficient proof. Besides, although the grand object of each is similar, the ways by which they strive to attain that object are very different; the Institute having, in fact, more claim to the title of a *society*, being composed only of those who have served the time of their articles in the profession; the Architectural Society, on the other hand, should rather be called *an Institute*, as one of its main objects is the forming a *school* of architecture for the younger members of the profession.

As the Architectural Society is thus steadily advancing, it is to be hoped that it will publish its Transactions at the end of the sessions (which it has hitherto only been prevented from doing, not from want of zeal or ability, but simply from want of finances), and then, laying claim to a charter and the Royal patronage, become a joint instrument with the Institute in directing the public taste, and in founding a National College of Architecture; when an architect will only be permitted to practice on his producing a diploma from each society; for it is only by mutual co-operation that this can be obtained.

Your obedient servant, SET-SQUARE.

[This communication must close the contention.—Editor.]

ON SETTING OUT SLOPES OF EXCAVATIONS AND EMBANKMENTS ON RAILWAYS.

Sir,—Seeing in the last number of your very excellent Journal, some remarks by Mr. Bruff on a method of setting out, on sidelong ground, the slopes of excavations and embankments, I have taken the liberty of suggesting another method, which in my opinion possesses some advantages over the one described by Mr. Bruff, in so far as it is more expeditious, and, taking into account the great liability to error in calculations made in the field, however simple and elementary they may be in themselves, also more accurate.

Fig. 1—Cutting.

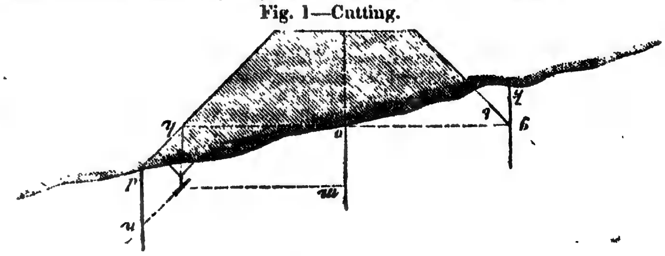


Fig. 2—Embankment.

* Mr. Johnson is still a member, being now in Italy, at the expense of the Royal Academy.

Fig. 1 represents a section of an excavation, in which *e f* is the surface of the ground and *o* the centre line of railway. The slopes being determined upon, had the ground been level, as *g ó h*, by measuring the distances *o g* and *ó h* on each side of the centre line, the tops of the slopes *g* and *h* would at once have been found.

Let, however, these distances be measured off and marked on the sloping ground at *k* and *s*; then, to find the top of the upper slope, place the *theodolite* at *s* and level to *m*, above the centre line; set the instrument now to the angle of the slope, and bring the staff to the higher ground, and move it about until you read the same height at *n* as you did at *m*. It is obvious, by inspecting the parallelograms *m h* and *h n*, that *d*, where the staff will then stand, is the point required.

To set out the lower slope requires the addition to the levelling staff of a leg, *g t*, capable of being set to any angle with the staff, and also of moving along it so as to be adjusted at any height. By placing the staff plumb at *k*, the leg being set to the angle of slope, and the top of it, *g*, on a level with *o*, it is clear that a line stretched along *g t*, and produced until it intersects the ground, will do so at the point *a*, which is the top of the slope required.

Fig. 2 is a section of an embankment which sufficiently explains itself. If you consider this of sufficient importance to merit a place in your useful miscellany, by inserting it you will oblige

Yours, &c.,

Halifax, November 19, 1838. DAVID W. BOWMAN, Engineer.

NEW ACT RELATING TO BUILDINGS.

The statute of 25 George III., c. 27, for the better regulation of buildings, and more effectually preventing mischief by fire, and by which a person was prohibited, in the penalty of 100*l*., from carrying on any manufactory for the distillation of turpentine, &c., in quantities above 10 gallons at a time, in any place within 75 feet of another building (except in buildings then in use for carrying on such manufactories), is repealed, so far as relates to the exception, by the act 1 and 2 Victoria, c. 39, passed at the close of last session; and the above penalty is declared to extend to the owner of any turpentine distillery within the distance of 75 feet from any other building, unless such other building adjoining the distillery be occupied jointly by the tenant of the latter, and the whole of such buildings (including the distillery and premises adjoining) be 75 feet distant from other buildings. The act contains, however, a proviso, that the proprietors of distilleries which have been in operation 30 years are not to be liable to the penalty until the 1st of August, 1840.

OVER ESTIMATES.

"They do these things better in France."—STERNE.

SIR,—We have heard a great deal from some parties about the defects of the English system of private engineering, and the advantage of a well organised government department. A great clamour has at the same time been raised, and much stress laid upon the excess which has taken place in most of the estimates for our English lines. The remedy is plain, according to these economists; but, as our fellow-countrymen may like to look before they leap, will you allow me to call their attention to the practical working of this superior system as exhibited in France, where great agitation now exists on the subject. In the case of the St. Germain Railway, the estimates of the Administration des Ponts et Chaussees amounted to only 6,000,000f. while the real expense exceeded 14,000,000f. In the same way the expenses of the Versailles and Meudon line have been estimated at only 5,000,000f., whereas it appears, to bring the line to Paris, 17 or 18,000,000f., at least, would be required. In the case of the Paris and Havre line, the estimate of this model Board of Works, instead of 90,000,000f., is expected to amount to 200,000,000f.

I leave these facts to speak for themselves, and the admirers of government boards to contemplate what they so much admire.

A FOE TO HUMBUG.

FRENCH MEASURES.

The following will be found simple methods of calculating, in round numbers, some of the French measures:—

To reduce English miles into metres, multiply by 16 and add two figures to the result, the true proportion is 1609.

To reduce metres into miles, cut off two figures and divide by 16.

To reduce yards into metres, multiply by 9 and cut off the last figure.

To reduce metres into yards, cut off the last figure and multiply by 11.

To reduce pounds sterling into francs, add two figures and divide by 4.

To reduce francs into pounds sterling, multiply by 4 and add two figures.

These rules will be found with all ordinary numbers to give a result within one per cent. of the truth.

GUILDHALL.

SIR,—As the City authorities have been making an alteration in Guildhall, by rendering the east end similar in style to the west, and decorating it with the statues of Edward VI., Queen Elizabeth, and Charles I., rescued from the coal cellar, may I be permitted, through the medium of your influential journal, to submit to the civic authorities another improvement. Some time ago, there was exhibited in the Hall some ancient tapestry and pictures, which are again consigned to oblivion and destruction in their former receptacles. Now, what I should beg leave to suggest is, that some of these objects might be well exhibited in the vaulted passage leading into the Hall from Basinghall-street, and which could be protected from injury by payment of a very small amount out of the 2,000*l*. per annum paid for watching the Hall. It was in a somewhat similar way that the French have used the temporary wooden galleries erected at the Louvre for a ball, as a place for the exhibition of their collection of tapestry. Yours, &c.,

A CONSTANT READER.

REPORT ON INTERNAL COMMUNICATION TAXATION.

The committee, after showing the great inequality which exists, steam boats paying nothing, railways ⅛d. per passenger per mile, stage coaches ½d., and post masters ¾d., recommends the abolition of all such taxation at the earliest possible period, and that, in the meanwhile, steam boats, railways, and stage coaches, should be charged one halfpenny per passenger duty for every four miles. In the evidence taken before the committee, Mr. Horne, the coach proprietor, states that great difficulty is sustained by the coachmasters on all lines of road where they are affected by steam navigation, as the east of England, as far as York and Edinburgh. Mr. Horne does not think that with a reduction of duties, nor without an abolition of tolls, that the stage coaches could come into competition with railways. He states that a similar effect is felt in Kent, but that coaches are started after October, on account of the bad weather. Mr. Robert Gray states, that were the post-chaise duty taken off, a great number would be kept by country innkeepers to convey passengers to the railways.

To this report is appended a return of the amount of mileage duty and composition paid by 18 working railway companies; among which, for the year 1837, are the Manchester, 7,485*l*.; Leeds and Selby, 2,235*l*.; Greenwich, 451*l*.; and the others various amounts, from 250*l*. and under. The total amount of duty was 10,296*l*., or one-fiftieth of the stage coach duties.

CITY IMPROVEMENTS.

SIR,—The city Commissioners of Pavements have recently erected disgusting stone lamp-spikes at each end of Cheapside, but I submit that their places might well have been occupied in another way. The city which can raise tens of thousands for a statue to the Duke of Wellington, could very easily have erected a statue to Milton near his birth-place, Bread-street, and another to Pope, near Lombard-street; at least they might have dedicated columns to their memory, as they have done in Farringdon-street, to two brawling politicians. All that has been done to commemorate Milton in the place of his nativity has been to dedicate Grub-street to his name.

A. C.

CHIMNEYS.

(From Dr. Ure's Dictionary of Arts, Manufactures, and Mines.)

Chimney is a modern invention for promoting the draught of fires and carrying off the smoke, introduced into England so late as the age of Elizabeth, though it seems to have been employed in Italy 100 years before. The Romans, with all their luxurious refinements, must have had their epicurean cookery placed in perpetual jeopardy from their kitchen fires, which, having no vent by a vertical tunnel in the walls, discharged their smoke and frequently their flames at the windows, to the no small alarm of their neighbours, and annoyance of even the street passengers.

Chimneys in dwelling houses serve also the valuable purpose of promoting salubrious circulation of air in the apartments, when not foolishly sealed with anti-ventilating stove-chests.

The first person who sought to investigate the general principles of chimney draughts, in subserviency to manufacturing establishments, was the celebrated Montgolfier. As the ascent of heated air in a conduit depends upon the diminution of its specific gravity, or, in other words, upon the increase of its volume by the heat, the ascensional force may be deduced from the difference between the density of the elastic fluid in the interior of the chimney, and of the external air; that is, between the different heights of the internal and external columns of elastic fluid supposed to be reduced to the same density. In the latter case, the velocity of the gaseous products of combustion in the interior of the chimney is equal to that of a heavy body let fall from a height equal to the difference in height of the two aerial columns.

To illustrate this position by an example, let us consider the simple case of a chimney of ventilation for carrying off foul air from a factory of any kind; and suppose that the tunnel of iron be incased throughout with steam at 212 degrees Fahr. Suppose this tunnel to be 100 yards high, then the weight of the column of air in it will be to that of a column of external air 100 yards high, assumed at 32° F. inversely as its expansion by 180°; that is, as 1000 is to 1·375; or as 72·727 is to 100. The column of external air at 32° being 100 yards, the internal column will be represented by 72·727; and the difference $= 27{\cdot}27$, will be the amount of unbalanced weight or pressure, which is the effective cause of the ventilation. Calculating the velocity of current due to this difference of weight by the well-known formula for the fall of heavy bodies, that is to say, multiplying the above difference, which is 27·27, by the constant factor 19·62, and extracting the square root of the product; thus, $\sqrt{19{\cdot}62 \times 27{\cdot}27} = 23{\cdot}13$ will be the velocity in yards per second, which, multiplied by 3, gives 60·30 feet. The quantity of air which passes in a second is obtained of course by multiplying the area or cross section of the tunnel by this velocity. If that section is half

a yard, that is = a quadrangle $2\frac{1}{4}$ feet by 2, we shall have $23{\cdot}13 \times 0{\cdot}5 = 11{\cdot}565$ cubic yards, $= 312\frac{1}{4}$ cubic feet.

The problem becomes a little more complicated in calculating the velocity of air which has served for combustion, because it has changed its nature, a variable proportion of its oxygen gas of specific gravity 1·111, being converted into carbonic acid gas of specific gravity 1·524. The quantity of air passed through well-constructed furnaces may, in general, be regarded as double of what is rigorously necessary for combustion, and the proportion of carbonic acid generated, therefore, not one half of what it would be were all the oxygen so combined. The increase of weight in such burned air of the temperature of 212°, over that of pure air equally heated, being taken into account in the preceding calculation, will give us about 19 yards or 57 feet per second for the velocity in a chimney 100 yards high incased in steam.

Such are the deductions of theory; but they differ considerably from practical results, in consequence of the friction of the air upon the sides of the chimneys, which varies likewise with its form, length, and quality. The direction and force of the winds also exercise a variable influence upon chimney furnaces differently situated. In chimneys made of wrought iron, like those of steam boats, the refrigeration is considerable, and causes a diminution of velocity far greater than what occurs in a factory stalk of well-built brick-work. In comparing the numbers resulting from the trials made on chimneys of different materials and of different forms, it has been concluded that the obstruction to the draught of the air, or the deduction to be made from the theoretical velocity of efflux, is directly proportional to the length of the chimneys and to the square of the velocity, and inversely to their diameter. With an ordinary wrought-iron pipe, of from 4 inches to 5 inches diameter, attached to an ordinary stove, burning good charcoal, the difference is prodigious between the velocity calculated by the above theoretical rule, and that observed by means of a stop-watch, and the ascent of a puff of smoke from a little tow, dipped in oil of turpentine thrust quickly into the fire. The chimney being 45 feet high, the temperature of the atmosphere, 68° Fahr., the velocity per second was,—

Trials.	By theory.	By experiment.	Mean temperature of chimney.
1	26·4 feet	5 feet	190° Fahr.
2	29·4	5·76	214
3	34·5	6·3	270

To obtain congruity between calculation and experiment, several circumstances must be introduced into our formulæ. In the first place, the theoretical velocity must be multiplied by a factor, which is different according as the chimney is made of bricks, pottery, sheet iron, or cast iron. This factor must be multiplied by the square root of the diameter of the chimney (supposed to be round), divided by its length, increased by four times its diameter. Thus, for pottery, its expression is $2{\cdot}06\sqrt{\frac{D}{L+D}}$; D being the diameter, and L the length of the chimney.

A pottery chimney, 33 feet high, and 7 inches in diameter, when the excess of its mean temperature above that of the atmosphere was 205° Fahr., had a pressure of hot air equal to 11·7 feet, and a velocity of 7·2 feet per second. By calculating from the last formula, the same number very nearly is obtained. In none of the experiments did the velocity exceed 12 feet per second, when the difference of temperature was more than 410° Fahr.

Every different form of chimney would require a special set of experiments to be made for determining the proper factor to be used.

This troublesome operation may be saved by the judicious application of a delicate differential barometer, such as that invented by Dr. Wollaston; though this instrument does not seem to have been applied by its very ingenious author in measuring the draughts or ventilating powers of furnaces.

If into one leg of this differential syphon, water be put, and fine spermaceti oil into the other, we shall have two liquids, which are to each other in density as the numbers 8 and 7. If proof spirit be employed instead of water, we shall then have the relation of very nearly 20 to 19. I have made experiments on furnace draughts with the instrument in each of these states, and find the water and oil syphon to be sufficiently sensible: for the weaker draughts of common fire-places the spirits and oil will be preferable barometric fluids.

To the lateral projecting tube of the instrument, as described by Dr. Wollaston, I found it necessary to attach a stop-cock, in order to cut off the action of the chimney, while placing the syphon, to allow of its being fixed in a proper state of adjustment, with its junction line of the oil and water at the zero of the scale. Since a slight deviation of the legs of the syphon from the perpendicular changes very considerably the line of the level, this adjustment should be made secure by fixing the horizontal pipe tightly into a round hole, bored into the chimney stalk, or drilled through the furnace door. On gently turning the stop-cock, the difference of atmospherical pressure corresponding to the chimney draught, will be immediately indicated by the ascent of the junction-line of the liquids in the syphon. This modification of apparatus permits the experiment to be readily rectified by again shutting off the draught, when the air will slowly re-enter the syphon; because the projecting tube of the barometer is thrust into the stop-cock, but not hermetically joined; whereby its junction line is allowed to return to the zero of the scale in the course of a few seconds.

Out of many experiments made with this instrument, I shall content myself with describing a few, very carefully performed at the breweries of Messrs. Truman, Hanbury, and Buxton, and of Sir H. Meux, Bart., and at the machine factory of Messrs. Braithwaite; in the latter of which I was assisted by Captain Ericsson. In the first trials at the breweries, the end of the stop-cock attached to the differential barometer was lapped round with hemp, and made fast into the circular peep-hole of the furnace door of a wort copper, communicating with two upright parallel chimneys, each 18 inches square, and 50 feet high. The fire was burning with fully its average intensity at the time. The adjustment of the level being perfect, the stop-cock orifice was opened, and the junction level of the oil and water rose steadily, and stood at $1\frac{1}{4}$ inches corresponding to $\frac{1{\cdot}25}{8} = 0{\cdot}156$ of 1 inch of water, or a column of air 10·7 feet high. This difference of pressure indicates a velocity of 26 feet per second. In a second set of experiments the extremity of the stop-cock was inserted into a hole, bored through the chimney stalk of the boiler of a Boulton and Watt steam-engine of twenty-horse power. The area of this chimney was exactly 18 inches square at the level of the bored hole, and its summit rose 50 feet above it. The fire-grate was about 10 feet below that level. On opening the stop-cock, the junction line rose $2\frac{1}{4}$ inches. This experiment was verified by repetition upon different days, with fires burning at their average intensity, and consuming fully 12lbs. of the best coals hourly for each horse's power, or nearly one ton and a third in twelve hours. If we divide the number $2\frac{1}{4}$ by 8, the quotient 0·28 will represent the fractional part of 1 inch of water, supported in the syphon by the unbalanced pressure of the atmosphere in the said chimney; which corresponds to $19\frac{1}{4}$ feet of air, and indicates a velocity in the chimney current of 35 feet per second. The consumption of fuel was much more considerable in the immense grate under the wort copper, than it was under the steam-engine boiler.

In my experiments at Messrs. Braithwaite's factory, the maximum displacement of the junction line was 1 inch, when the differential oil and water barometer was placed in direct communication with a chimney 15 inches square, belonging to a steam boiler, and when the fire was made to burn so fiercely, that, on opening the safety-valve of the boiler, the excess of steam beyond the consumption of the engine, rushed out with such violence as to fill the whole premises. The pressure of one-eighth of an inch of water denotes a velocity of draught of 23·4 feet per second.

In building chimneys, we should be careful to make their area rather too large than too small; because we can readily reduce it to any desired size, by means of a sliding register plate near its bottom, or a damper plate applied to its top, adjustable by wires or chains, passing over pulleys. Wide chimneys are not so liable as narrow ones to have their draught affected by strong winds. In a factory, many furnace flues are often conducted into one vertical chimney stalk, with great economy in the first erection, and increased power of draught in the several fires.

Vast improvements have been made in this country, of late years, in building stalks for steam boilers and chemical furnaces. Instead of constructing an expensive, lofty scaffolding of timber round the chimney, for for the bricklayers to stand upon, and to place their materials, pigeon-holes, or recesses, are left at regular intervals, a few feet apart, within the chimney, for receiving the ends of stout wooden bars, which are laid across, so as to form a species of temporary ladder in the interior of the tunnel. By means of these bars with aid of ropes and pulleys, everything may be progressively hoisted, for the building of the highest engine or other stalks. An expert bricklayer, with a handy labourer, can in this way raise, in a few weeks, a considerable chimney, 40 feet high, 5 feet 8 inches square outside, 2 feet 8 inches inside at the base, 28 inches outside, and 20 inches inside at the top. To facilitate the erection, and at the same time increase the solidity of an insulated stalk of this kind, it is built with three or more successive plinths, or recedures, as shown in *fig.* 281. It is necessary to make such chimneys thick and substantial near the base, in order that they may sustain the first violence of the fire, and prevent the sudden dissipation of the heat. When many flues are conducted into one chimney stalk, the area of the latter should be nearly equal to the sum of the areas of the former, or at least of as many of them as shall be going simultaneously. When the products of combustion from any furnace must be conducted downwards, in order to enter near the bottom of the main stalk, they will not flow off until the lowest part of the channel be heated by burning some wood shavings or straw in it, whereby the air syphon is set agoing. Immediately after kindling this transient fire at that spot, the orifice must be shut by which it was introduced; otherwise the draught of the furnace would be seriously impeded. But this precaution is seldom necessary in great factories, where a certain degree of heat is always maintained in the flues, or, at least, should be preserved, by shutting the damper plate of each separate flue, whenever its own furnace ceases to act. Such chimneys are finished at top with a coping of stone-slabs, to secure their brickwork against the infiltration of rains, and they should be furnished with metallic conducting rods, to protect them from explosions of lightning.

COMPANION TO THE ALMANAC FOR 1839.

Reserving a fuller notice of this publication for our next Number, we shall merely state at present that the architectural section is more copiously illustrated than usual, and that the wood cuts manifest considerable improvement. Among them are a view of the Athenæum, Hotel, &c., at Derby; a view and ground plan of the Victoria Rooms, Bristol; a section of the Fitz-william Museum, Cambridge; and a view of the new London and Westminster Bank; all which subjects, as well as many others, are fully described in the letter-press.

COLES' PATENT ANTI-FRICTION RAILWAY CARRIAGES.

Fig. 1.—Perspective View of a Carriage.

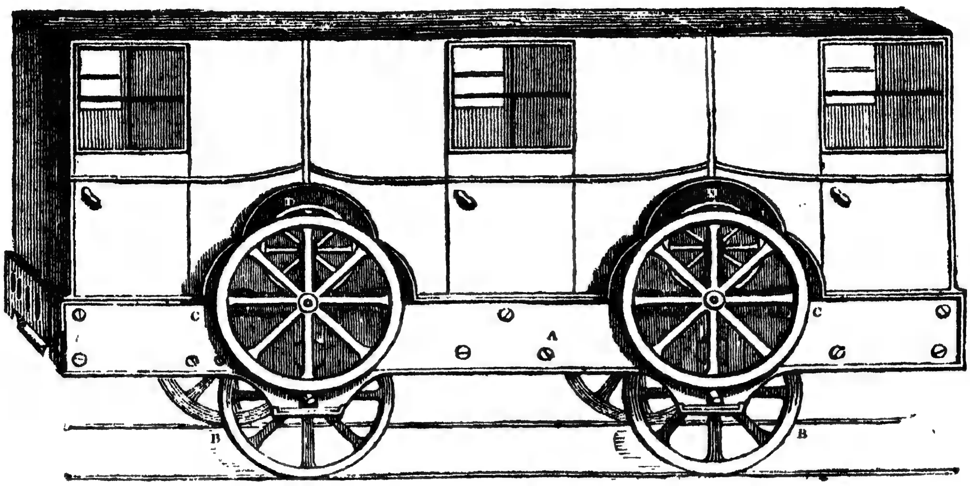

Fig. 2.—Plan of the Carriage Framing.

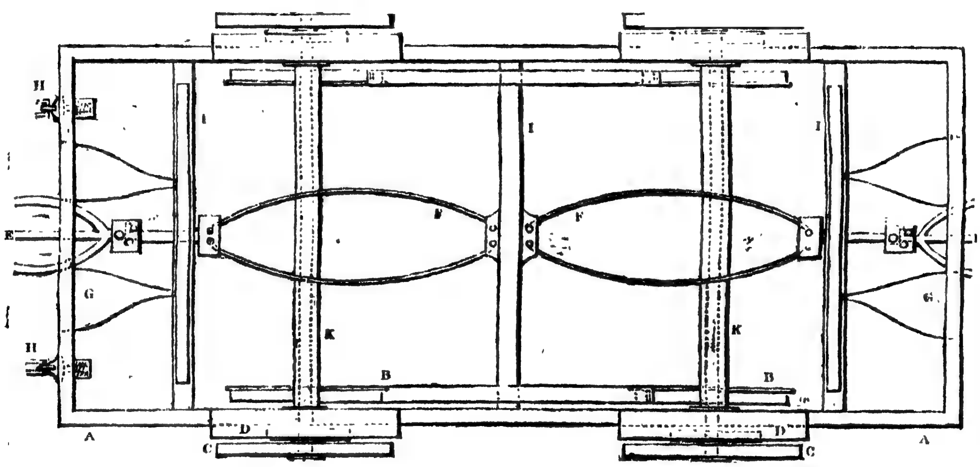

Fig. 3.—Transverse View, showing the Running Wheels and the Anti-friction Wheels.

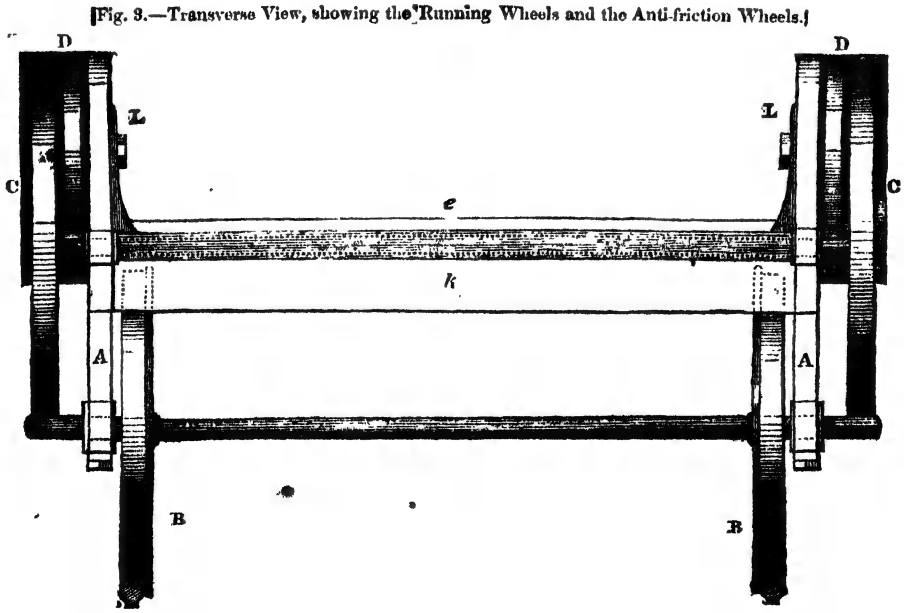

COLES' PATENT ANTI-FRICTION WHEEL RAILWAY CARRIAGES.

In a former number of the Journal (No. IX., p. 226) an engraving and short description of the above carriages were given. I now forward some additional drawings and description, which will better illustrate the construction of the carriages and the application of the anti-friction wheels, and the buffing apparatus.

"The object of my invention or improvement in carriages, more particularly for railways or tramroads, is, in the first place, to reduce the friction upon the axles of the wheels on the rails, and by the introduction of two-wheel carriages, prevent that contact when turning curves upon the rail, to which four-wheel carriages are always liable; secondly, to ameliorate the effects of concussions of such carriages one against the other. The former consists in a novel or improved arrangement of anti-friction wheels or rollers, which bear upon the axles of each other, thereby transferring the weight of the body and its contents from the axle of the quickest motion to that of the slow motion; whilst the latter consists in an improved construction and arrangement of elliptic spring buffers and spring fastenings to connect the same, for the purpose of reducing or ameliorating the concussion of one carriage against the other, or of the engine or tender: all of which improvements are exhibited in the accompanying engravings, as applicable to two-wheel or four-wheel carriages.

Fig. 1 is a perspective view of a four-wheel railway carriage, with my improvements applied thereto; fig 2 is a plan or horizontal view of the carriage-framing of the same; fig. 3 represents a transverse view of the wheels: A A is the framing of the carriage; B B, the running wheels, having anti-friction wheels C C bearing upon their axle; D D are smaller anti-friction wheels bearing upon the axles of C C. The axles of the upper wheels are fixed, and do not revolve with the wheels. The middle and lower axles, with their boxes or collars, work up and down in a groove of the framework of the carriage. The whole weight of the load and frame is borne off by the upper friction wheels: E E are strong iron bars, which pass through each end of the carriage, and are bolted or attached to an iron which passes through one cross stay, and is thereby connected to the spring buffer; which buffer is also affixed to a similar iron attached to the other cross stay, against which the spring buffers are protected from being too much compressed or elongated, care being taken to allow sufficient room for the action of the springs either way; F F, the spring buffers; G G are two springs, fixed in the cross stay, and pressing against the connecting rod to keep it in a straight line to receive the bolt which connects the carriages; H H are two dovetail irons fitted into grooves, with chain to each; and also a bolt, which passes through the end of the carriage and through a coiled spring fitted into a box for that purpose, and connected to the next carriage. This mode of attaching the carriages renders them secure and flexible, and when pulling sideways have always two bearings to draw from, and when going straightforward, three; I I I are three cross stays, to which the springs and the spring buffers are attached; K K are two circular tubes, forming also stays, under which the middle axle works, and through the ends of which the upper axles are screwed and bolted; L L are two supports for the upper axles, to confine the wheels in their place, with screws to fix them.

"The two-wheel carriage differs from that above described, by having only two cross stays and one spring buffer; the axle of the upper wheels passes through the body of the carriage, and likewise forms a stay for the upper part of the frame.

"I claim, as my invention or improvement in carriages, the novel and peculiar adaptation of the mode of employing the friction wheels; and, thirdly, the peculiar adaptation of spring buffers and spring fastenings, as shown in the above drawings, or otherwise.

Having given the above description, I will now point out what I consider the advantages of my patent. It will be seen, by reference to the drawings, that the running wheels, and also the large anti-friction wheels, have only the friction of the collar, weighing about eight or ten pounds, whereas, in the common carriage, the friction of the whole, weighing from four to five tons, is thrown on the axle of the running wheels, which often produces such a great heat as to cause the axle to enlarge and the orifice of the collar to contract, no matter whether the collar be in one piece or in parts, thereby preventing the oil passing between the surfaces to lubricate the bearings. This is a very frequent occurrence when travelling at a great speed, and obliges the engineer to keep a good look-out to check the velocity of the train, when such an occurrence is likely to take place, so as to prevent any serious accident. The axle and collar may become so united by friction as to prevent the wheel revolving; but that never can be the case with the anti-friction wheels, even if the carriages were propelled five times faster than one with common bearings; moreover, the motion of the large anti-friction wheels, supposing they had to sustain the friction of the whole weight of the carriage, would be ten times less than the running wheels; but, when the whole weight is borne by the upper friction wheels the motion is only one-sixtieth part, and the heat produced, most probably, would not be one-thousandth part as great as that of the running wheels; consequently, the saving in oil or grease would be very great, notwithstanding that the bearings are as three to one.

A model may be seen of a carriage with the anti-friction wheels, propelled at the speed of seventy miles an hour. Here there is a weight equal to three ounces as a propelling power when the anti-friction wheels are in action, while a power of eighteen or twenty ounces is required when they are out of action, and the friction of the whole weight is thrown on the axle of the running wheels; and whether the weight be reduced or increased, the same proportion of propelling power will be necessary to give the carriage motion. Therefore, by reducing the friction of the carriages to one-sixth part, the engine or propelling power will be enabled to draw an increased load, as six to one; or, in other words, an engine of one-sixth the power will be capable of propelling the same load.

3, Charing-cross. W. COLES.

CORNISH STEAM ENGINES.

ON THE EFFECTIVE POWER OF THE HIGH PRESSURE EXPANSIVE CONDENSING ENGINES IN USE AT SOME OF THE CORNISH MINES. BY THOMAS WICKSTEED, M.INST.C.E., COMMUNICATED IN A LETTER TO THE PRESIDENT OF THE INSTITUTION OF CIVIL ENGINEERS.

I am induced to address you again* upon the subject of the engines used in the mines in Cornwall, from the very kind manner in which you received my last paper.

I have been lately into Cornwall, having been instructed by the Directors of the East London Water Works Company to proceed there for the purpose of examining an engine that was to be disposed of by the East Cornwall Silver Mining Company, with a view of purchasing it for the company's works at Old Ford. The result was, that the engine, whose cylinder was 80 inches in diameter, was purchased, and is now being removed to London, and I expect that by this time next year it will be at work here.

While in Cornwall, I was very desirous of making such a trial of one of the engines as might be satisfactory to the London engineers, and trust that I have succeeded in my object.

I received permission to make a trial of the engine upon the Holmbush Mines near Callington, and beg to give you the following detailed account thereof.

The diameter of the cylinder was fifty inches; the sizes of the pumps, or "boxes," as they are termed in Cornwall, and the height of the lifts, are as follows, viz:—

	Fath.	ft.	in.		
Tye lift - - -	42	2	6	Diameter of pump -	11 inches.
Rose lift - - -	37	5	6	Ditto - - - - - -	11 „
Bottom lift - -	8	5	6	Ditto - - - - - -	10 „

The chief points to which my attention was directed, were the quantity of coals consumed, and the actual quantity of water lifted.

I saw 94lbs. (a Cornish bushel) of coals weighed, and had the stoke-hole cleared, and the coal bins and stoke hole doors sealed; and in addition to these precautions, besides my own observation, I had one of my young men stationed in the boiler-house during the time of trial, so that I am quite satisfied that no more than 94lbs. of coals were used.

Before the trial I ascertained exactly the length of the pump stroke, which was eight feet one inch, and caused the engine to work slowly that I might have sufficient time to measure the quantity of water delivered per stroke. The water was delivered into a wooden cistern, with a valve to let the water out when I had measured it. Finding that six separate measurements produced as nearly as possible the same result, the greatest variation being 2 per cent., I then weighed the quantity of water delivered by each stroke, and found it to be equal to $285\frac{6}{10}$lbs. I had a rod made the exact length of the stroke, namely, 8 feet 1 inch, and during the trial measured the stroke frequently; it varied from 8 feet 1 inch to 8 feet 2 inches. I have in my calculations taken the shortest length.

The diameters of the pumps, and the exact heights of the lifts, were taken very carefully.

TRIAL.

The fire under the boiler was worked down as low as could be without stopping the engine. The pressure of steam was 40lbs. per square inch *in the boiler;* I took the counter and the time, and then started the engine. At the end of 2¼ hours the fire was lowering, and the speed of the engine reducing, and it was necessary to have more fuel. The 94lbs. of coal having been consumed, the engine was then stopped, and the counter again taken. It had made 672 strokes, or very nearly 5 strokes per minute. The weight of water raised was (285·6lbs. × 672 strokes =) 191,823·2lbs.; the height to which it was raised (was 42fath. 2ft. 6in. + 37fath. 5ft. 6in. + 8fath. 5ft. 6in.) = 535ft. 6in. the weight multiplied by the height in feet is equal to 102,721,323lbs. of water lifted one foot high with 94lbs. of coals.

This result, however, although it shows how much water was actually

* For previous communication, see Vol. I. of the Transactions of the Institution of Civil Engineers.

raised to the surface, does not show the duty of the engine, for although, in consequence of leaks and defective valves the quantity raised is not so great as it would be were it possible to have every part perfect, nevertheless the engine has to raise the quantity due to the areas of the pumps, multiplied by the length of the stroke, under the pressure due to the columns of water equal in height to the lifts, notwithstanding that in consequence of the defects mentioned, the whole quantity may not reach the surface; the fair mode, therefore, of calculating the duty of the engine, during the trial, would be as follows:—

	lbs.
Weight of column of water 11 inches diameter, and 42fath. 2ft. 6in., or 254·5 feet in height	10,498
Ditto - - ditto - - 11 inches diameter, and 37fath. 5ft. 6in., or 227·5 feet in height	9,384
Ditto - - ditto - - 10 inches diameter, and 8fath. 5ft. 6in., or 53·5 feet in height	1,824
Load upon engine	21,706

21,706 × 672 strokes × stroke $8\frac{1}{12}$ feet = 117,906,992lbs. weight lifted one foot high with 94lbs. of coals.

From the foregoing it will be seen that 191,823lbs. of water, were raised 535 feet 6 inches high with the expenditure of 94lbs. of coals, and that the duty of the engine was equal to nearly 118 millions of pounds raised one foot high. I should observe, that the engine had not been overhauled, or any thing done to it to prepare for the trial, which was not determined upon (as regarded the engine upon which the trial was to be made), until the previous day. The boiler and flues had not been cleaned for eleven months.—My object was to prove what could be done by an engine worked upon the expansive principle, and I therefore considered that a trial for two hours would prove the capability of the engine, although, most probably, the average duty of the engine for twelve months would not be so great as it was for the short time that it was under trial. I am perfectly satisfied the trial was a fair one.

I was not able to ascertain what the pressure of steam was when it first entered the cylinder, having no indicator with me; but the engineer, Mr. West, stated that the steam was wire drawn and reduced from 40lbs. above the atmosphere, which was the pressure in the boiler, to 30lbs. above the atmosphere upon entering the cylinder.

The steam was cut off at one-sixth the stroke. The steam in the jacket round the cylinder communicates directly with the boiler, and radiation is completely prevented, by the casing round the jacket; consequently a high temperature is preserved, which is absolutely necessary to obtain the full effect from the expansive force of the steam.

The following will show what effect could have been produced by the steam power, provided the engine and pump gear had worked *without* friction.

Pressure of steam when first admitted into the cylinder (30lbs. + 14·75lbs. —1·5lbs. deducted for imperfect vacuum) = 43·25lbs.

		lbs.	
For $\frac{1}{6}$ of the stroke, the pressure was		43·250	per square inch.
When the piston had made $\frac{2}{6}$ of its stroke the pressure was reduced to		21·625	
Ditto	$\frac{3}{6}$	14·416	
Ditto	$\frac{4}{6}$	10·812	
Ditto	$\frac{5}{6}$	8·650	
Ditto	$\frac{6}{6}$	7·208	
		6)105·961	
Mean pressure of steam		17·66lbs.	

The area of cylinder was	1963·5 square inches.
Mean pressure of steam per square inch	17·66lbs.
Number of strokes	672
Length of stroke in cylinder (being one foot longer than in shaft)	9ft. 1in.

Power of steam 1963·5 sq. in. × 17·66lbs. per sq. in. × 672 strokes × $9\frac{1}{12}$, length of stroke, = 211,658,702lbs. raised 1 foot high with 94lbs. of coals; now as the effect produced was 117,906,992, the friction of the machinery was equal to 93,751,710lbs. raised 1 foot high, or about $7\frac{3}{4}$lbs. pressure per square inch. As the friction of a water-works pumping engine is about $5\frac{3}{4}$lbs. per square inch, it may be safely inferred, that an engine when working upon the expansive principle at a water-works will do more work than it does in the mines; to those who have seen the heavy pump rods, balance bobs, &c., attached to a mining engine, it will appear very evident.

In the observations I have had opportunities of making, I am very well satisfied that the engine I am about to erect at the East London Water-Works will do a duty equal to at least 120 millions.

As it had been observed that the expansive principle would not answer for rotary or double engines, I was induced to make some observations upon a double engine working the stamps for breaking the copper ores at the Tincroft Mines, and I beg leave to give you the details.

The diameter of cylinder	36 inches.
Length of stroke	9 feet.
Length of crank	3 feet 6 inches.
Steam was cut off in down-stroke at	$\frac{4}{5}$ths.
Ditto - - - - - up-stroke at	$\frac{1}{3}$rd.
Number of strokes per minute	10

The engine worked with a very equal velocity, in fact there appeared no irregularity whatever in the motion; Captain Paul, the agent of the mine, allowed me to examine the coal accounts, from which it appeared, that the average consumption of coals for the engine was 30 bushels for 24 hours.

The engine was working,—1st, a set of stamps; 2nd, a pump; 3rd, a crushing machine: and 4th, a trunking machine. The last two pieces of machinery had lately been added, and previous to this increase of machinery, it appeared from the books, that the consumption of coals was equal to 27 bushels, of 93lbs. each, in 24 hours.

The stamping machinery worked 48 lifters; to ascertain the weight of them, I examined an account showing the weight of 26 of the cast iron heads when new, and found the average weight to be 3 cwt. 12lbs. each, these are used until the weight by wear is reduced to 1 cwt. 2 qrs., the average weight will therefore be (3 cwt. 12lbs. + 1 cwt. 2 qrs. ÷ 2) = 2 cwt. 1 qr. 6lbs. The weight of the wood work of the lifter, the iron straps, washers, &c., I found by trial to be 1 cwt. 3 qrs. 24lbs., making the total average weight of the lifter and head (2 cwt. 1 qr. 6lbs., + 1 cwt. 3 qrs. 24lbs.) = 4 cwt. 1 qr. 2lbs. or 478lbs. The average height the stamps were lifted was 10 inches, and the 48 stamps were lifted 5 times per stroke.

The following calculations will show the duty performed by the stamping engine.

48 lifters × 478lbs. × 0·833 feet, height lifted, × 5 times per stroke × 10 strokes per minute, × 60 minutes per hour, × 24 hours per diem, 1,376,089,344 lbs. lifted one foot high in 24 hours.

The diameter of the pump was	14 inches, or 1·069 sq. ft. area.
Length of stroke	6 feet.
Strokes per minute	10
Lift	26 feet.

Duty performed 1·069 sq. ft. × 6 ft. × $62\frac{1}{2}$lbs. per cubic ft., × 26 ft. lift × 10 strokes per minute, × 60 minutes × 24 hours = 150,087,600lbs. raised one foot high in the 24 hours.

DUTY OF ENGINE.

1,376,089,344 = 150,087,600 ÷ 27 bushels = 56,525,072lbs. lifted one foot high, with a bushel or 93lbs of coals.

The single engine at the Holmbush mine was, during the time of my experiment, doing the work of 26·48 horses; thus the experiment lasted $2\frac{1}{4}$ hours, or 135 minutes × 33,000lbs., lifted 1 foot = 4,455,000lbs., which would be lifted 1 foot high by the exertion of 1 horse's power in $2\frac{1}{4}$ hours. 117,906,992lbs., ÷ 4,455,000 = 26·48 horses' power. The coals consumed were equal to 94lbs. or (94lbs. ÷ 26·48 horses' power ÷ 2·25 hours) = 1·57lbs. of coals per horse's power per hour. The coals used by one of the pumping engines at Old Ford in an experiment lasting 1 hour, tried upon the 18th of February 1835, were equal to 4·82lbs. per hour per horse's power, or three times the consumption of the Cornish engine, notwithstanding the extra friction in a mining engine.

The double engine at the Tincroft mines was doing the work of 32·11 horses; thus 33,000 × 60 minutes × 24 hours = 47,520,000lbs. lifted 1 foot high by the exertion of one horse's power during 24 hours. The engine lifted 1,526,176,944lbs. 1 foot high in the 24 hours; 1,526,176,944 ÷ 47,520,000 = 32·11 horses' power. The coals consumed were 27 bushels of 93lbs. each, or 2,511lbs. ÷ 24 = 104·62lbs, per hour ÷ 32·11 horses' power = 3·25 lbs. of coals per hour per horse's power.

Mr. Farey, in his valuable treatise on the steam engine, states at page 488, that a rotary or double engine of Bolton and Watt's construction, will require $10\frac{1}{2}$lbs. of coals per hour per horse's power, or three times the consumption of the Tincroft double engine.

Old Ford, Aug. 7, 1837. THOMAS WICKSTEED.

MORECAMBE BAY EMBANKMENT.

To Sir H. Le Fleming Senhouse, and the Gentlemen forming the Provisional Committee of the "Caledonian, West Cumberland, and Furness Railway."

Gentlemen,—In obedience to instructions received from you in February last, I examined Morecambe Bay and the Dudden Sands, for the purpose of determining the most eligible points, and ascertaining the practicability of carrying railway embankments across those estuaries, and diverting the courses of the rivers; and in a letter addressed to Sir H. Le Fleming Senhouse, in March last, I briefly stated my opinion upon the subject. Since then, having received more particular instructions to survey, and give in plans and estimates of the expenses, and report my opinion as to the best mode of forming those embankments, and diverting the rivers, with the view to the formation of a company, and an application to Parliament to carry those objects into effect, I now beg to lay before you the result of my labours.

Having obtained the assistance of Mr. Padley, of London, who has had much experience in making surveys and taking levels for railways, I, early in June, commenced my operations. I first inspected the terminus of the Preston and Lancaster Railway, at Lancaster, and examined the intervening country to Morecambe Bay, in order to fix upon the most desirable line of railway from Lancaster, and the best point for the embankment to cross the bay. I then examined the eastern shores of the bay, and took such levels of the sands, and trials of the substrata, as I considered necessary; proceeding round the bay, viewing the entrance of the rivers and streams falling into it, and the surrounding country to Ulverstone. At Ulverstone I made inquiries respecting the trade of that port and the other places round the bay, and as to the local interests generally, to learn, as far as pos-

sible, to what extent those interests might be affected by the intended embankment and railway, and the diversion of the channels and rivers. I then examined the eastern shores and sands of Morecambe Bay, from Ulverstone to Rampside, and the peninsula of Low Furness, lying between Morecambe Bay and the Duddon, and round the Duddon sands by Ireleth and Broughton, to the south-westernmost point at Hodbarrow. After these preliminary steps, I commenced taking levels, soundings, and measurements, on the Duddon, to ascertain the distances, the height of the tides, the depth of water, and, from borings, the nature of the substrata under the sands. I then proceeded in the same manner with my surveys, measurements, levels, soundings and borings, on Morecambe Bay.

Upon a careful examination and consideration of all the circumstances and localities, I am of opinion, that the object the committee have in view is perfectly feasible, and that there is not any difficulty in an engineering point of view, in carrying a railway across these two bays. I recommend that the railway should commence at the terminus of the Lancaster and Preston line, proceeding, at about a mile radius, round the eastern side of the town of Lancaster to the river Lune, passing that river between the old and new bridges near to Skirton, and from thence in a straight line to the south of Torrisholme and Poulton to Morecambe Bay, at Poulton Ring. From this point the embankment should be carried across the bay to a point of land in Low Furness, which I have called Leonard's Point, lying to the north of the Gleaston river or Beck, and to the south of Newbiggin; from thence the railway will go in nearly a straight direction to the south of Dendron and Dalton to the Duddon Sands at Ronhead. The embankment across the Duddon to be taken from Ronhead Crag to Hodbarrow point in Cumberland. The length of the embankment across Morecambe Bay will be 10 miles and 51 chains, and that across the Duddon 1 mile 65 chains. The mode of making the railway embankments across Morecambe and the Duddon Sands, I propose should be as follows :—

I commence, on each side of the bay, by driving four rows of piles, the width of the railway, 21 feet apart from centre to centre, across the bay, with longitudinal timbers on the top; these timbers to be strengthened by diagonal struts or braces from the piles to the under side of the timbers, the piles to be well secured together by cross braces at the upper ends. The piles are to be driven through the sand into the clay a sufficient depth to render them quite safe. This is done by machinery constructed for the purpose, fixed upon a platform about 60 feet long, mounted upon wheels, which will move forward with the work. On the platform is fixed a carpenters' shop, to protect the men, and enable the work to go on in all weathers. The rails are laid on the longitudinal timbers as the work proceeds. On the sea side of the piles, close to the first row, I drive sheet piling, grooved into each other as high as the present line of the sand, to about two feet into the clay. This is to prevent the water making its way through the loose sand, and undermining the foundations. I have proved, from borings in various places across the bays, that the substrata under the loose sand is clay. The levels of the upper surface, and the substrata of clay, will be better seen from the section accompanying this report.

While this is going on, the coffer-dams, tide-gates, and bridges, will also be in progress, so that the whole may be completed at the same time. The level of the railway will be 6 feet above the highest, or 30 feet spring tide.

I then commence making the embankments, by running carriages, loaded with materials, on the railway, and dropping stones therefrom between the piles, to fill up the hollows, so as to make a level line or dam across the bays; the bottom of the carriages will be made to open, so that the whole line may be filled in at the same time. As the filling up proceeds, and the embankments gradually rise, the action of the sea will assist in forming a beach with a natural inclination. The waves, when propelled forward in a body by the winds, tides, and currents, possess the power to move the rolling mass of sand and other substances with them in their course, until they meet with some obstruction or point of rest. After striking the beach or embankment in an upward direction, they break and lose their force, and, in receding over a gently inclined and equal surface, they are incapable, in an exhausted state, of returning the sand or substances back to the level from whence they had forced them. Taking advantage of what nature herself points out, is the best mode by which artificial sea embankments may be formed. A great part of the materials for the embankments will thus be brought in by the waves, tides, and currents, and a natural sea-beach will be forming until the works are completed to high water-mark; after which rubble, earth, binding gravel, and small stones, will be filled in from the top of the railway. I propose to cover the seaside of the embankments with binding gravel, to the thickness of about two feet, and upon the top of that three or four feet of small stones, making a slope of about seven to one on the sea side, and two to one on the land side, of the embankments.

In regard to the time which will be occupied in completing the contemplated works, I am of opinion, that within two years from the work being fairly commenced in Morecambe Bay, the piling, framework, bridges, and tide gates, can be completely finished, and the communication effectually and safely opened across the bay. The same works would be completed in much less time across the Duddon. And the embankments can be completed in eighteen months more; making, altogether, a period of three years and a half from the commencement.

The embankment in Morecambe Bay—exclusive of the spans allotted for bridges—I calculate will require, altogether, 10,453,785 tons of material. Of this quantity, 6,149,379 tons will be brought in by the sea and furnished in the bay during the progress of the works, in the manner described above. The remainder, viz, 4,304,406, will consist of small stones, binding gravel, and other material, and will be furnished from the cutting in Furness and on the Poulton shore. I do not propose to interfere with the present channels of the rivers inside the proposed embankment, until the sea beach is completed. On the outside of the embankment it will be necessary to keep the channels open, and which I should do by working a drudging-engine. This will, at the same time, assist in forming the bank.

As the embankments rise, the tide-gates will be arranged so as to regulate the quantity of water inside the bays. When the tide ebbs to the level of the embankments, the water is then regulated by the sluices to prevent its running over the embankments, and disturbing the sand and other substances brought in by the sea. A portion of the tidal waters being for the time kept inside of the embankments, will allow the silt and mud to deposit, and thereby tend to raise and improve the quality of the land to be reclaimed. On the ebb of the tide the water from the land and rivers being let out through the sluices, and conducted near the shore, navigable channels will thus be formed under the protection of the land, and by carrying down sand and silt will aid the action of the returning tides in forming and strengthening the sea beach at the base of the embankments. By working drudging-engines along the lines of the desired new channel, their courses will soon be formed. In most parts the material found and taken out of the new channels, will be sufficient to form the banks, but in some parts facine work will be necessary. These banks will be of sufficient height to protect the adjoining lands from the highest spring-tides. The navigation to the ports inside of the embankments will not be interrupted, as vessels may pass through the tide-gates and bridges at stated and proper intervals, and when the embankments are completed the vessels will pass along the new channels. On the north-west side of Morecambe Bay I propose to direct the new channel for the waters from the Leven and Crake rivers into a basin close to the entrance of the Ulverstone Canal, which will be so constructed as to scour and keep itself clear of mud and sand, and will materially improve the port of Ulverstone, as ships may then lay close to the shore. Over this channel a draw-bridge will be made, and after the embankment is completed the tide will be allowed to flow up and down, so that whenever there is a sufficient tide in the river ships will be able to pass up to Ulverstone with much more certainty and security than at present.

At the entrance I also propose to place pointed gates, which, in the event of an extraordinary high tide, can be shut, and thus the land inside protected from the damage consequent upon such high tide.

On the east side of Morecambe Bay, I propose to have tide-gates to allow the passage of small vessels into the new channels to be made for the waters from the Kent and Wynster rivers. From the best inquiries I could make I have not found the traffic up these rivers of sufficient magnitude to require a draw-bridge.

During the progress of the embankments, or when raised to near high-water mark, and before the tides can be altogether shut out, no fears need be entertained by proprietors of land round the bay, that they will be more inconvenienced than they at present are at high tides—as the water inside of the embankment may be gradually lowered through the sluices, on the decrease of the tides from spring to fall. A parapet bank or wall of earth will be raised about six feet above the level of the railway, on the side of the embankments next the sea, to protect them from the wind and spray.

This report is accompanied by plans, sections, and models, which will better explain the position of the proposed embankments across the two bays, the line of railway from Lancaster to Morecambe Bay, and across the peninsula of Low Furness, and the branch railway to Ulverstone, as well as the intended new channels, tide-gates, &c., and the mode by which the operations are intended to be carried into effect.

As regards the expenses of these various works, I estimate that the timber, iron, materials, and workmanship, for the piles, frame-work, railway, and embankment, tide-gates, drawbridge, &c., on Morecambe Bay, will amount to 289,359*l.* 14s. 10d.; and the expenses of forming the new channels on each side of this bay, to 73,501*l.* 6s.—making the expenses for Morecambe Bay 362,861*l.* 0s. 10d., or about 34,111*l.* 10s. per mile, calculating the distance at 10 miles 51 chains. The same works on the Duddon will amount to 55,870*l.* 8s. 6d., and the new channels to 15,400*l.*—making the expenses for the Duddon 71,270*l.* 8s. 6d., or about 39,322*l.* per mile, calculating the distance at 1 mile 65 chains. The total expenses for the embankments, &c. of the two bays, will thus be 434,131*l.* 9s. 4d. The reason why the Duddon is more expensive is, that the cost of the erections on each side are as great as on Morecambe Bay, whilst the distance is so much less.

The quantity of land which will be reclaimed by means of these embankments and works, I estimate at about 52,000 acres—namely, about 46,300 acres in Morecambe Bay, and 5,700 acres in the Duddon; and taking the land at 23*l.* per acre, on an average, the total value of the land to be reclaimed will be 1,196,000*l.*

The remaining part of the line will pass through a district of country peculiarly favourable, and presenting no obstacles of importance. As, however, this is now being surveyed by Mr. Rastrick, I forbear making further comments. I am, however, justified in stating that, although the cost of the two embankments will be considerable, I am well satisfied, that the total average cost of the whole line from Lancaster to Maryport will be much under that of most of the existing railways.

A railway is, or will shortly be, opened to Preston; and, in the course of the ensuing year, one will be opened to Lancaster; and with the Caledonian, West Cumberland, and Furness Railway carried into effect, the communication will be complete from London to Carlisle, a distance of 301 miles: and, in such case, there can be little doubt but a line will be continued from Carlisle to Glasgow, thus forming a chain of railway communication from London through the great agricultural, commercial, mining, and manufacturing districts of Scotland, alike profitable and beneficial to both countries, and which will also greatly facilitate the communication with the north of Ireland. The en-

closure of Morecambe Bay and the Duddon Sands, and the reclaiming of so great an extent of land, at present overflowed and unproductive, may be considered of itself an object of national importance; and, no doubt, will be favourably looked upon and supported by the Government.

Being only required, by my instructions, to report as to the practicability of forming embankments across the two bays, and the diversion of the rivers, I do not feel called upon to enter into a comparison of the advantages which this line of railway will possess over the other projected lines through the mountainous districts of Westmorland, or of the eastern line through Yorkshire, Durham, and Northumberland; or to enlarge upon the benefits calculated to arise to the public generally, or to the local interests in particular. I will merely observe, that the "Caledonian, West Cumberland, and Furness Railway," if carried into effect, must be greatly advantageous to the existing railways from London to Lancaster, and Maryport to Carlisle—promote the commerce and industry, and improve the value of property, in the districts through which it passes—and cannot be otherwise than ultimately profitable to the shareholders who may engage in the undertaking.

I have the honour to remain, Gentlemen,
Your obedient servant,
36, Cable-street, Wellclose-square, London. JOHN HAGUE.

ON LIMESTONE AND CALCAREOUS CEMENTS.

BY ARTHUR AIKIN, ESQ.

(*From the Transactions of the Society of Arts.*)

When men began to assemble themselves in society, and to occupy fixed habitations, the first great work on which to employ their common exertions would be, surrounding the space covered by their huts by a mound or wall, in order to keep out wild beasts and their still more dangerous human enemies. With this view, the most favourable situation that could be chosen would be a detached rocky hill, of moderate height, flat-topped, and having its flanks more or less protected by inaccessible precipices. On the more gently sloping sides a wall would be raised by collecting the largest blocks lying about, and laying them on one another; at the same time so adapting their irregular surfaces as to leave between them the least possible spaces, and filling up these spaces with smaller pieces of stone. Walls of this kind, if skilfully built, and with blocks of large dimensions, even if not united into one mass by the use of cement, oppose, by the mere magnitude and weight of their ingredients, great impediments to disintegration, either from natural causes or external violence. If the hill thus occupied were massive in its structure, like granite or basalt, the blocks furnished by it would be of very indeterminate figures, and the face of the wall would present the appearance of irregular polygons, which would require, on the part of the builders, considerable skill to arrange without insterstices. But, if the hill were composed of beds or strata, lying over one another, then the blocks would offer at least two parrallel faces, and thus would be far more easy to arrange as a wall. Examples of this very antique mode of building, generally known by the name of Cyclopean, are by no means unfrequent in Greece and in Italy, especially in that part of it formerly called Etruria. Mycene, in Peloponnesus, is very remarkable for its gateway and walls of Cyclopean architecture, which we know to have resisted the utmost efforts of the Argians to demolish, at the time they took the city, and have since, for a long series of centuries, continued to brave the destructive rage of barbarians and of the elements. Even in more regular and elaborate structures of hewn stone, where the blocks are large, and the surfaces of pressure well levelled, the use of cement may be dispensed with, as is the case in the antique temples of Upper Egypt.

But where, from choice or necessity, the materials of building are pieces of small size, whether regular or irregular in figure, it is impossible to make of them solid and durable constructions without the use of cement of some kind interposed between the pieces, in order to bind them together. Every one who has travelled through the hilly districts of this country, must have observed the dry stone walls by which the fields are enclosed, and probably have personally experienced the ease with which a breach may be made, even in those that are the most carefully and solidly built. We know, from the concurrence of sacred and profane history, that one of the earliest seats of the human race was the alluvial plain watered and periodically inundated by the Euphrates. In this district neither rocky strata nor detached blocks of stone are to be found, but a tenacious and silty soil offers to the ingenuity of man materials capable of being moulded into artificial stone, that is, bricks, of any desirable form. It is impossible to make bricks of very large dimensions, as the clay would infallibly crack in drying, as well as in baking. While, therefore, we learn from historical authority that the structures of ancient Babylon were raised in brick, we know, from the testimony of modern travellers, who have examined the ruins, that these bricks are not more than about 13 inches square by about three inches thick. From this fact we might infallibly conclude, even in the absence of all direct evidence, that cement of some sort must have been employed in raising walls and other solid buildings of such materials. Bitumen, in a melted state, was, as we are informed by Herodotus, and by the author of the book of Genesis, the substance made use of on this occasion; and this statement is confirmed by recent observers, who not only inform us that at Hit, a district a little higher up the river than the ruins of Babylon, there are even now numerous springs of petrolium; but that what seem to be the oldest parts of the ruins themselves, are constructed of layers of unburnt brick, faced by layers of burnt ones; the whole cemented together by bitumen and mats made of reeds. But the knowledge and use of calcareous cements was either contemporary with that of bitumen, or was invented shortly after; for among these very ruins occur many parts built of burnt brick set in lime-mortar, which latter, even at the present day, is of extreme toughness and hardness.

But no ancient people seem to have made so much use of calcareous cements as the Romans, for, with the exception of the cloaca maxima, or great sewer—a prodigious subterranean vaulted tunnel, constructed, in the reign of their king Tarquinius Superbus, of blocks of a light and porous stone, without any cement whatever—with the exception, I say, of this great work, all the other public structures appear to have been of brick or stone, cemented by lime mortar. Nor was it in raising buildings alone, in the usual acceptation of the term, that calcareous cements were employed by the Romans; the chief of their military roads and highways were pavements resting on a foundation of rough stones consolidated into one mass by liquid mortar or grout, which, beginning at Rome itself, accompanied and facilitated the march of her conquering legions to the very remotest extremities of the empire. The port of Ostia, at the mouth of the Tiber, was a place of immense consequence, as commanding the whole water communication of the capital with the provinces, and great exertions were made, by the construction of moles and jetties, to convert the naturally hazardous and exposed entrance of the river into a secure and capacious harbour. The fashion, also, among the more opulent classes, of quitting Rome during the heats of summer, for a residence in the numerous villas on the shores of the bays of Naples and Baiæ, and which were frequently constructed on moles actually projecting into the sea, rendered necessary the invention of a cement capable of preserving its efficacy even under water. Accident or experiment, discovered near the town of Puteoli (itself situated on the bay of Baiæ) a bed of porous, half-concreted matter, which, when reduced to powder and mixed with lime, or with common mortar, gave to it the property of hardening under water. The substance described by Vitruvius and by Pliny, by the name of powder of Puteoli (Pulvis Puteolanus), still retains essentially the same appellation; only, as the name of the town has been modernized into Pozzuoli, so that of the substance has passed into that of puzzolana.

If the description given by Julius Cæsar of the towns in the south-eastern part of Britain, which, from its vicinity to the continent of Europe was also the most civilized, be at all correct, it is highly probable that the use of calcareous cements was not known in this country till after its conquest by the Romans. Of the buildings erected by them the greater part have now perished from the effects of time and of violence; but some of the simpler kinds still remain sufficiently entire to show their style of building, and the durability of their materials. The most ancient limestone quarries in the kingdom, and which continue still in full activity, having been originally opened by the Romans, are at Tadcaster, in Yorkshire, the name of which place in the Roman itineraries is, from this circumstance, called Calcariæ.

The essential ingredient of all calcareous cements is lime, a substance which never occurs naturally in a pure state, being always combined with some other body, as well as mechanically mixed with impurities of various kinds. The usual state in which it is found is as an earthy salt, called, when crystallized, calcareous spar; and, when massive, limestone, being combined with carbonic acid in the proportion of about 54 of lime to 46 of carbonic acid in the 100 parts.

The natural state of carbonic acid, under the ordinary atmospheric pressure and temperature, is a gas, or permanently elastic fluid; and as this gas is but sparingly soluble in water, it follows that when we put a piece of limestone in a glass, and cover it with water, and then add any substance capable, by combining with the lime, of separating the carbonic acid, this latter will rise through the water in a stream of bubbles, producing that appearance which the chemist calls effervescence. Most acids, when dissolved in water, will separate carbonic acid from lime in the way I have just described; and hence we are furnished with an easy test for distinguishing limestone from sandstone, and from other usually occurring rocks, by its almost entire solubility, accompanied by effervescence, in cold dilute muriatic, or nitric acid; the proportion that remains undissolved indicating with considerable, though not perfect, accuracy, the amount of impurities.

Every kind of limestone is not equally adapted to the use of the bricklayer; and, as these differences depend partly on mechanical and partly on chemical properties, it becomes necessary to describe somewhat in detail the principal varieties of limestone, as far as their economical use is thereby affected. With this view they may conveniently be arranged into four families.

The first includes those limestones which are, for the most part, of a pale colour, and burn to a white lime, containing very little foreign matter.

Of these, the purest is white granular or statuary marble, which contains hardly any impurities, except a little silicious earth. This is actually used by the chemist, when he wants a lime purer than usual; but as, when heated it is very liable, on account of its granular crystalline structure, to fall into a coarse powder, it is manifestly incapable of being burnt in a common limekiln, and therefore is of no use as a material for mortar.

White chalk is another of this family, which, on account of its softness and porousness, is easily quarried, and requires less fuel and a shorter time for its burning than common gray limestone does. It has, however, this disadvantage, namely, that the cores or centres of those pieces that have been only superficially burnt, are easily broken down with the back of a spade, and therefore are often mixed up with the other ingredients of the mortar, instead of being scrupulously rejected, as they ought to be.

Oolite is another limestone of this family, and derives its name from the small round grains or concretions of which it is principally composed, and which were formerly supposed to be the eggs of fish in a petrified state. In

hardness, and other qualities, it holds a place intermediate between chalk and gray limestone.

Gray limestone, itself, includes all those beds in mountain limestone and in transition limestone which, with a structure passing from scaly into compact, are decidedly harder than the preceding, and require the assistance of gunpowder to detach them from the quarry, unless where they occur in very thin beds. They take, in burning, a longer time and somewhat greater quantity of fuel than the preceding, and are often mere aggregates of corals and other organic remains. The amount of impurity, chiefly sand and clay, rarely exceeds four or five per cent., and the darker varieties usually furnish the whitest lime, showing the colour to be chiefly carbonaceous.

The second family includes the swinestones and bituminous limestones; the first name being given to them from the fetid smell, like that of a pig-sty, produced by rubbing them against any hard substance. Their colour is dark brown, passing into black; all the varieties of black marble being of this kind. When heated red-hot, the carbonaceous colouring matter begins to re-act on the carbonic acid, converts it into another gas called carbonic oxide, which, having no attraction for lime, flies off, leaving behind the lime itself, of a snow-white colour, and rendered perfectly caustic, in a shorter time, and by a less expenditure of fuel, than is required for any other kind of limestone. Being, when burnt, more porous than any other of the compact limestones, it falls down into an exceedingly fine powder, by the action of water, or on exposure to the air; a quality which renders it particularly valuable to the farmer, as well as to the builder.

The third family is that of the magnesian limestone. Its chief repository in this country is that very extensive formation called the new red sandstone, which, in the natural series, lies immediately above the coal measures: here it occurs in thick beds, as well as occasionally in the mountain limestone. Its colour is sometimes reddish, but usually is of a pale yellowish brown. Many varieties have so greatly the aspect of fine grained sandstone, that they were for a long time considered as such; but a minute inspection will show that they are an aggregate of small rhomboidal crystals, which on analysis prove to be compounds of carbonate of lime and carbonate of magnesia, the relative proportions of which, though subject to considerable variation, may be stated at about three-fifths carbonate of lime, and two-fifths carbonate of magnesia. If a piece of this limestone be put into cold dilute nitric acid, it will dissolve very slowly, with hardly any sensible effervescence, although in hot acid the effervescence will be as vigorous as with common limestone. When burnt to lime, it retains its causticity for a much longer period than common lime does; and, therefore, no doubt modifies to a certain degree the properties of the mortar into the composition of which it enters, although its precise action has hitherto been very little investigated.

The fourth and last family includes those limestones which contain in their composition so large a proportion of iron and clay as to enable them to form cements, which have the property of becoming solid under water, and, therefore, are peculiarly valuable in subaqueous constructions.

One of these is the gray chalk, or chalk-marl. The bottom bed of the great deposit of chalk is considerably thicker than the upper ones, and contains no flints; in colour it is of a less pure white or gray, and is considerably harder than the upper chalk, so that many parts of it make a tolerably good building stone. In composition it is not uniform; the proportion of slightly ferruginous clay that it contains, notably increasing from the top to the bottom of the bed: the lower parts moulder by exposure to weather; and the lowest of all not only moulder, but are more or less slaty in structure; that is, are in the state of true marl. That part of the gray chalk which is used for water cement, contains various proportions of clay, from six or eight, up to about 25 per cent., and after burning has a pale brownish yellow colour. It is known in the London market by the name of Dorking lime, there being very extensive quarries of it near that town, as well as at Merstham and Halling.

Another and still more valuable variety of limestone for water cement. is the blue limestone, which is generally of a dark dove colour, and of a dull earthy aspect: by long exposure to weather it becomes, superficially at least, of a liver brown, and when burnt into lime is of a buff colour. It forms occasional beds in the transition and mountain limestone deposits, but constitutes nearly the whole of the lias limestone. This latter is one of the most remarkable of the English strata. Its geological position is between the lower oolite, and the new red sandstone. It passes obliquely through the country in a direction from N.E. to S.W.; from the sea coast at Whitby, to the cliffs at Lyme-Regis in Dorsetshire, on the British Channel. In its course southward it passes to the east of York, and crosses the Humber near the junction of the Trent and Ouse; thence it passes through the western edge of Lincolnshire, and traverses the counties of Nottingham, Leicester, Warwick, and Gloucester; its breadth in this part of its course being pretty uniformly about six miles. Hence the main body proceeds in nearly a southerly direction through Somersetshire to the coast of Dorset, while a broken line of the same skirts along the southern shore of the Bristol Channel as far as Watchet, and appears on the northern shore in detached patches in the counties of Monmouth and Glamorgan. The entire thickness of this deposit is perhaps about 250 feet; the middle part consists of beds of blue limestone alternating with blackish slaty marl; the upper and lower parts, being less calcareous than the middle, are composed chiefly of beds of marl, in which are harder masses of a compressed globular figure, less clayey than the slaty marl in which they are found, but less calcareous than the blue limestone. The quarries of Watchet, Aberthaw, and Barrow, in Leicestershire, were long celebrated for the excellent water lime which they produce, before it had been ascertained from geological surveys that they are only on different parts of the same deposit. From an analysis by Mr. Smeaton of the blue limestone of Watchet, Aberthaw, and Bath, the proportion of iron and clay in each appears to be the same, or about 11½ per cent. The blue lime of Barrow, according to Mr. Marshall, contains about 14, and according to Smeaton, 21·3 per cent. of the same ingredient, and that of Westbury, 9 per cent. The lias limestone used by the London builders, is brought from Lyme-Regis, but is little used in the metropolis, being about 25 per cent. dearer than Dorking lime, the difference in cost depending, in part at least, on the longer time and greater quantity of fuel required in burning it.

The balls which I have mentioned as occurring in the upper and lower beds of the lias formation, are not peculiar to it, but appear to be formed in all deposits of bluish slaty clay that contain carbonate of lime, but not sufficient to separate from the rest of the ingredients into distinct beds of limestone. Thus, in several of the beds of blue clay that lie above the chalk in that district called the London Basin are to be found layers of compressed spheroidal balls, known by the name of septaria, or cement stone. The outer part of them consists of obscurely slaty concentric layers, with an excess of clay, and which peel off by long exposure to the air; the interior part is more compact, and is not unfrequently divided into nearly cubical pieces by cracks generally filled or lined with calcareous spar. They may be observed in the cliffs of London clay that form the eastern coast of the island of Sheppy, also in the low cliff at Southend, at the mouth of the Thames; and they have been dug up wherever excavations have been made in the London clay, as at the archway road at Highgate, and in the deep cutting and tunnelling now going on for the London and Birmingham railway, near Primrose-hill. Of late years these stones, burnt and reduced to powder, have been very extensively used in all water building and other masonry requiring particular care, with such success as to have entirely superseded the employment of puzzolana, and of Dutch tarras. With this concludes my survey of the calcareous raw materials employed in the construction of cements, in which I have begun from the purest kinds of limestone, and have terminated with those which contain the smallest proportions of carbonate of lime.

Two other sorts of materials now require a short notice. The first comprehends a few non-calcareous substances, the essential ingredients of which appear to be oxid of iron and burnt clay, which have the power of giving to mortar made of white lime the property of becoming extraordinarily hard, and of setting under water.

Of these, puzzolana is volcanic ashes, thrown out of Vesuvius during its eruptions, and concreted, on the places where it has fallen, into a cellular mass of a rusty colour, and of slight cohesion.

Tarras, or trass, is a bluish black cellular trap or lava, quarried at Andernach on the Rhine into mill-stones; the fragments produced in making which are sent to Holland, where they are ground into powder: and when mixed with lias lime form a cement, extensively used in the dykes and other water buildings of that country.

In England, Rowley rag, a basalt obtained from the Rowley Hills in Warwickshire, and in composition probably very similar to the Andernach stone, has been used for the same purposes with good effect.

The other non-calcareous ingredient employed in the composition of mortar is sand, which, with reference to this use of it, may be divided into the pure and the clayey, the coarse and fine-grained, the round and the sharp-angled. Smeaton has shown by actual experiment, that raw clay sensibly impairs the hardness of mortar; it is obvious, therefore, that the use of pit-sand, which is generally dirty, should be avoided where it is possible, unless it has been previously cleaned by washing till it no longer troubles the clearness of the water. As the action of sand in mortar seems to be merely mechanical, that which is sharp-angled is evidently better than that which is round, as offering a better surface for the adhesion of the lime; it is likewise manifest that a due admixture of coarse and fine sand will fill a space, leaving the smallest interstices, and, therefore, capable of greater resistance to external pressure. Where chalybeate springs rise out of sand, the colour of this latter is yellow, from the intermixture of ochre; and such sands, if free from clay, produce a cement of extraordinary hardness.

Limestone, even when reduced to the finest powder, is wholly inefficacious in the composition of mortar, and it is only useful for this purpose when the carbonic acid has been driven off from it by a high heat continued a sufficient length of time. The fetid limestones, as I have already mentioned, may be wholly deprived of their carbonic acid at a lower heat than is required for the other limestones. In these latter it is probable that no difference in intensity of heat is required, but a longer continuance of it, according as the limestone under operation is more or less clayey, and more or less compact. The separation of the carbonic acid begins from the outside of the pieces, and so proceeds to the centre. The size, therefore, of the pieces before burning should be as small as is consistent with the expense of breaking them. It may easily be judged whether a kiln of limestone has been perfectly burnt by taking a few samples, and selecting a piece as big as a pea from the middle of each, and then dropping them separately into a glass containing weak muriatic acid. If no effervescence ensues, the burning has been complete, and the degree of its incompleteness may be estimated by the vigour of the effervescence as compared with that of an equal piece of the same limestone unburnt.

As soon as the lime has grown cold, it begins to reabsorb carbonic acid; and, in course of time, will fall to pieces, and return to the state of carbonate; there is, therefore, an obvious advantage in using lime as soon as possible after it has been burnt; there is, however, a considerable difference in the rate at which different limes recover their carbonic acid; the white limes take it up the most rapidly, and the argillaceous and magnesian ones the most slowly. In an experiment by Mr. Marshall, a piece of white Bristol lime

kept in a drawer, was found, in seven days, to have increased in weight 33 per cent.; while a piece of blue lias from Westbury, in the same time, and in the same place, had increased no more than 10½ per cent. In close casks, the lias lime will keep good for a long time. Smeaton's experience goes as far as seven years; but, in this case, the lime was previously reduced to powder by slacking with water, and then was trodden hard down into the casks.

When cold water is poured on a piece of perfectly well-burnt lime, it is rapidly absorbed, and in great abundance; the piece becomes warm, then cracks, gets hotter than the hand can bear, exhales a large quantity of steam, and finally falls down into a dry powder, almost as fine and impalpable as flour. To appearance, the whole of the water is evaporated; but the great heat produced, shows that very energetic chemical action has taken place; and, on weighing the lime, it will be found to have increased in weight 24·2 per cent., which increase is nothing but water combined with the lime into a solid substance, and which no heat short of redness will separate from it. This compound is called hydrate of lime, or slacked lime; and it is this, and not lime itself, which enters into the composition of mortar. Lime will not combine with water if it retains its carbonic acid; and, therefore, those pieces that are very imperfectly burnt, remain as lumps or cores after the rest has fallen to powder; and if these lumps are too hard to be broken by a blow of a spade, the mortar is all the better for their exclusion.

By the addition of a little water, hydrate of lime may be made into a stiff paste, which, in a short time, will become dry, and will retain its form, although it possesses scarcely any hardness or tenacity, and a shower of rain will wash it all away. It is only by the admixture of sand and other hard substances that it acquires the properties of a mortar or cement. The proportion of sand that can be incorporated into mortar, depends partly on the fineness or coarseness of the sand itself, and partly on the nature of the lime; but, as the sand is the cheaper ingredient, there is always a temptation to excess on this side. Pliny mentions that the failure of buildings at Rome in his time was owing to a deficiency of lime in the mortar; the proportions being 1 of lime to 4 of sharp pit-sand, and 1 of lime to 3 of round-grained sand from the sea or river: he likewise adds, that the quality of the mortar is greatly improved by the addition of a third part of pounded tiles. The common London mortar is made of 1 part white chalk lime, and 2½ of clean sharp river sand; but, not unfrequently, dirty pit sand is substituted for the latter, and the lime itself being very imperfectly burnt, a mixture is the result which never becomes hard, and has only a very imperfect adhesion to the bricks. White lime, when really good, will take a larger proportion of sand than the brown limes will, but, in the London practice, the reverse generally prevails; an additional proof of the badness of common chalk lime. Although it be certain that lime has a considerable chemical attraction for silica in a state of solution, or, perhaps, of very fine division, yet it seems improbable that any action should exist between the two, when the silica is in grains of sand, especially considering their hardness, and, consequently, the strong adhesion between the particles of which they are composed; yet there are certain facts and points of practice which can hardly be explained, unless this be admitted. The cohesion of a paste of hydrate of lime is not greater than that of a paste of carbonate of lime or chalk, and if the action of sand were merely mechanical, it is not easy to understand why it should form, with hydrate of lime, a strong cement, and not with chalk. It was an ancient law in Rome, that after the ingredients of mortar had been rubbed together with a little water, the mass should be kept in a covered pit for three years before being used; and we are expressly informed by Pliny, that buildings erected during the operation of that law were not liable to cracks. It was likewise an ancient practice (and Smeaton has confirmed the advantage of it by his own experience) to beat the mortar for a long time with a heavy pestle, just before being used; the effect of which would be, not only more thoroughly to mix the ingredients, but to rub off from the outside of the grains of sand the compound of lime and silica, if such had been formed, and, by incorporating it with the mass, dispose it the more rapidly to consolidate. Mr. Smeaton also found that mortar made with white lime, is far more improved by repeated beating, than cement formed of argillo-ferruginous lime, which is satisfactorily accounted for by assuming (and it may be done with great probability) that the combination of part of the lime with the clay is effected in these latter limestones during the process of burning. The same excellent observer also found that if two samples—one of well-beaten mortar, and the other of mortar mixed only in the usual way—be afterwards diluted with water to the state of grout, the former will set sooner and become harder than the latter, which is all in favour of chemical action taking place between the ingredients. This combination of lime and silica (perhaps, I ought only to say this supposed combination) appears, however, to be decomposable by the carbonic acid of the atmosphere, just as silicate of potash is; for, by long exposure, the lime in mortar will regain the greater part, but, probably, not the whole of its original carbonic acid. Thus Mr. Tennant found that common mortar, which had been exposed to the air for a year and three quarters, had regained only 63 per cent. of its full quantity of carbonic acid; and Mr. Marshall found that some mortar from Pickering Castle, some centuries old, had regained not more than 86 per cent. of its carbonic acid. I may also mention, as having some relation to this question, that many attempts have been made to burn old mortar, with the expectation of bringing it again into a state capable of forming a cement when mixed with water, but without the smallest success.

Of water cements there is a great variety, both as relates to the ingredients themselves and their composition; some of the principal of which I shall now proceed to notice. The only cement employed by the Roman builders, in the erection of moles and other structures in the sea, was 1 of lime, and 2 of puzzolana.

Mr. Smeaton's cement, which he employed in building the Eddystone Lighthouse, was equal measures of Aberthaw lime in the state of hydrate and in fine powder, and of puzzolana, also in fine powder; proportions which, if reduced to weight, and due allowance be made for 24 per cent. of water in the lime, differ not materially from those recommended by Vitruvius. The cement was also well beaten, till it had acquired its utmost degree of toughness, and, probably, therefore, till chemical action had begun to take place.

The gray chalk of Dorking forms the basis of a number of excellent cements, for use both in water and on land. The composition of that which is most generally used is 1 of lime to 3 or 3½ of sharp river sand; and for filling-in the interstices of thick walls, 1 of lime to 4 of coarse gravelly sand.

The piece of brick-work on the table is part of the boundary wall of the East India Dock, built in 1804, and taken down in 1834. It was cut off a large block, carried away on a truck, and afterwards chiselled into shape, without the cement giving way in the slightest degree. It was composed of 1 part Merstham lime, and 4 parts gravelly sand dug out of the excavation of the dock; and if this sand was, like that dug out of the London Docks, deeply coloured with yellow ochre, the extraordinary goodness of it is very satisfactorily accounted for, and it differs from two other specimens before you only in the circumstance that the former of these contains 2 of the same kind, and the other 5.

To the same class of cements belong a specimen composed of 1 lime, and 3½ of sand dredged out of the Thames, and two concretes or pebble mortars; the former of which was composed of 1 lime and 7 river ballast, and the latter of 1 lime and 8 clean-washed shingle.

Tarras mortar, made of white lime and tarras, requires long and repeated beating to bring it to perfection; probably, in consequence of the tarras not having previously been roasted. And the evidence of chemical action among the ingredients of this cement is unquestionable, by its *growing*, as the workmen call it, in the joints of the masonry, owing, no doubt, to the expansion of the tarras, in proportion as it is acted on by the lime.

In the cements made with lias, or argillo-ferruginous limestone, the clay and oxide of iron seem to have combined with the lime during the burning, forming a compound capable of uniting with great firmness, and without much difficulty, with an additional portion of sand, or of burnt ferruginous clay; the quantity of this latter admissible into the cement being probably the less, as the amount of the same in the lime itself is the greater. Lias is but little used in London, on account of the greater cheapness of yellow chalk, which answers nearly the same purpose, but is not so strong. It was, however, employed in the cement used for setting the bricks that form the facing of the London Docks, to the depth of 14 or 18 inches from the outside. The precise composition of the cement was—

4 lias lime,
6 river sand,
1 puzzolana,
1 calcined iron stone,
—
12.

The celebrated ash-mortar, or *cendrée* of Tournay, may be mentioned as perhaps, the best of the lias cements. It is thus prepared. After the large pieces of lias are withdrawn from the kiln, there remain a quantity of small fragments, mixed with the ashes, of the very slaty coal, which is the fuel employed, in the average proportion of 3 of ashes and 1 of lime. Of this mixture, about a bushel at a time is taken, and is sprinked with water only sufficient to slack the lime; the whole quantity, thus treated, is then put into a pit and covered with earth, where it remains for some weeks. It is then taken out, and well beaten by an iron pestle for half an hour, which brings it to the consistence of soft mortar; it is then laid in the shade for a day or two dry, and again beaten till it becomes soft. This is repeated three or four times, till at length it is only just sufficiently soft for use; being then applied to brick or stone, it forms, in a few minutes, a very compact mass, and, after twenty-four hours, has acquired a stony hardness.

The process and its effects are well worthy of notice. The coal-ash is chiefly burnt clay, in a state of fine division, and, therefore, well fitted to combine rapidly with the argillo-ferruginous lime. By bringing the lime to the state of hydrate, and allowing it to remain for some time in contact with the ash, a commencement of combination in all probability takes place; this is carried farther by the process of beating, during which the lime parts with its water, and combines with the ash; and when, by a continuance of this process, no increase of moisture is produced, it may be presumed that nearly perfect combination of the lime and ash has happened, and the cement is then ready to set and become solid.

I have already explained what the balls are of which Roman cement is formed, namely, a limestone more highly charged with ferruginous clay than even lias limestone; so that they may, without impropriety, be considered as containing not only the calcareous ingredient, but the ferruginous clay also required for the composition of cement. On this account it is that, when burnt, so little of their lime is in a state to become hydrate, that, though when moistened with water the mass will heat, it will not fall to powder, but requires to be ground, and, when afterwards beaten, it will form a hard cement without any further addition. It is, however, capable of combining into a firm mortar, with a considerable proportion of sand, either alone or mixed with yellow chalk lime, which considerably reduces the cost,

and, at the same time, produces an excellent cement, either for land or water building. The cement stones are prepared for use by making a judicious selection of them, breaking them into pieces about two inches cube, stratifying them with coal in a kiln, and burning them for several hours. One bushel of coals, with careful management, will roast eight bushels of cement. The kiln is kept in constant activity, and the roasted stones are taken out immediately from the kiln to a mill, where they are ground to powder. This powder is then, without delay, to be packed in tight casks, as exposure to the air much weakens it, although it may be kept for many months in an open place, without becoming quite effete. The best cement powder, when mixed and prepared for use, has a dusky green colour, and I am informed that some of the manufacturers are in the habit of mixing the burnt stone, before grinding, with certain proportions of copper slag, a substance consisting chiefly of sulphuret of iron and oxide of iron, and, therefore, an exceedingly valuable addition, if not too liberally employed. The two bricks on the table have been cemented with a compound of 1 yellow lime, 2½ of pulverised copper slag; and I observe, on the surface of the cement, a saline efflorescence, which, in stucco and other dry work, might prove detrimental.

Oxyde of iron in almost any state, but especially when not fully oxydized, such as smiths' scales, roasted iron ore, &c., is also a very useful ingredient, giving firmness and the property of setting under water to mortars made of white lime, and adding to the peculiar characteristic excellences of those made with brown or yellow lime.

The general theory that seems to me to explain with fewest difficulties the nature of calcareous cements is the following:—

In the white limes, or nearly pure carbonates of lime, the only effect of burning them is to drive off the carbonic acid. By slacking, the lime becomes a hydrate, and, in this state, is capable of acting chemically, though feebly, on the surface of pure siliceous sand. This combination causes the first setting of the mortar, which is also strengthened by the mere mechanical action of the sand. The greater part, however, of the lime has not combined with the sand, but remains in the state of hydrate; in proportion as it absorbs carbonic acid from the air, it gives out its water and passes to the state of carbonate: such mortar, therefore, acquires its final induration and dryness when the whole of the hydrate has been decomposed, and the water replaced by carbonic acid. In losing 22 per cent. of water, it combines with 46 per cent. of carbonic acid, and, therefore, the mortar becomes the more solid and strong.

In the blue limes, part of the calcareous matter combines, during the burning, with the intimately mixed ferruginous clay, forming a compound that gives to the cement made of it the property of setting speedily in the air or under water. The rest of the lime passes, by slacking, into the state of hydrate; and, if only siliceous sand is present, acts on it in the same manner as white lime does; but if ferruginous sand, or burnt ferruginous clay be present, the hydrate acts more rapidly and powerfully on the clay, sooner gives out its water, and consolidates: whether this latter compound is afterwards decomposable, by exposure to the carbonic acid of the air, I do not presume to determine.

In those limes that contain naturally so much ferruginous clay as, after burning, to form cements without the addition of sand or other ingredient, the greater part of the lime is probably combined with the clay in the act of burning, a very small quantity of hydrate will be formed, and very little carbonic acid will be reabsorbed.

PROCEEDINGS OF SCIENTIFIC SOCIETIES.

ROYAL SOCIETY.

At a meeting of the Royal Society on Thursday, the 22nd of November, the chairman, Mr. F. Baily, put in nomination the Marquis of Northampton, as president. As, in conformity to the by-laws, no other Fellow was proposed for that office, the election of his lordship took place at the anniversary on St. Andrew's Day.

ROYAL ACADEMY.

On Monday, Nov. 5, a general assembly of the Academicians was held in Trafalgar-square, when Mr. W. C. Ross, Mr. D. Roberts, and Mr. R. Westmacott, were elected associates.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

The council contemplate the formation of a students' class, composed of young men studying as architects, and under 21 years of age. It is proposed that the rooms should be open to them two evenings in the week, and that one of the Fellows should attend, under whose superintendence they should sketch subjects. They are to pay one guinea per annum, and to have access to the books and collection, and the *entrée* to the lectures and ordinary meetings. Prizes, also, will be awarded to those who most distinguish themselves by their attendance and studies.

ARCHITECTURAL SOCIETY.

The Society commenced the session for 1838-39 with a conversazione, which was held at the Society's Rooms, 35, Lincoln's Inn-fields, on Tuesday evening, 6th November. William Tite, Esq., F.R.S., F.G.S., President, in the chair.

The secretary read the report from the committee, which commenced by stating that, notwithstanding the very difficult and extraordinary position in which the society had been placed, the present session opened under happier auspices, and with brighter prospects than, perhaps, it ever had the good fortune to do. It referred to the occasion on which their late president (Mr. Clarke) took leave of the members, prior to his departure to the continent, where he was about to travel and remain for some years. He expressed himself as still most anxious to promote the interests of the society during his absence, by obtaining the attention of foreign architects, and of his promise to transmit, from time to time, whatever information appeared to him valuable, and likely to prove acceptable to the society and that he should still continue to be one of its most attached members. The report alluded to the laudable exertions made by the student members in the competition of the session, and mentioned the names of Messrs. Morgan, Rutherford, Nunn, and Williams, as having received the prizes in the departments of measured drawing, original sketches, and essay composition.

The subjects for competition for the present session were announced as follows:—*In the Class of Design*—subject, Marine Baths; to be an isolated building, with principal front facing the sea. *In the Class of Drawing*—the principal front of St. Mark's Chapel, North Audley-street; and *in the Class of Essay Composition*—the treatment of the Ionic order in the various buildings of the ancients. The prizes to be awarded—

In the Class of Design, to be a pair of Silver Compasses.

In the Class of Drawing, to be Sir W. Chambers' Civil Architecture.

In the Class of Essay Composition, to be Hope's Architecture.

The report enumerated the donations to the library and museum, and also to the funds of the society. To the latter, W. Tite, Esq., subscribed 30 guineas; and Mr. G. Smith, one of the vice-presidents, 20 guineas.

The president delivered a very suitable and appropriate address, which reverted to the resignation from the chair of the late president, and his own election; the grounds upon which he accepted the office, and his reasons of so doing. He then recommended a course of study requisite for the architectural student; and, by way of strengthening his own opinion, gave some extracts from Vitruvius: he also stated his intention to advance the interests of the society to the best of his ability, and announced his intention to read papers occasionally during the session.

The president then called the attention of the meeting to Mr. Whishaw's hydraulic telegraph, and to some highly finished specimens of locks and other fastenings, which had been forwarded as patterns of workmanship by Messrs. C. Smith and Son of Birmingham. There were also exhibited several other works and drawings; some of the portfolios were very interesting, and attracted considerable notice; so did a very highly finished and beautiful model of the Epi scopal chapel now erecting in the cemetery ground at Norwood.

The meeting was very fully attended; and from the lateness of the hour at which the company separated, it may fairly be supposed that they were well satisfied with the business of the evening.

INSTITUTION OF CIVIL ENGINEERS.

In our last number, page 383, column 2, we gave the substance of a communication from Mr. Buck read before the Institution, in which there is an error. For the word "*unanimous*" read "*maximum*."

SOCIETY OF ARTS.

At the ordinary meeting held on Wednesday evening, November 21, Mr. J. Taylor in the chair, six new members were elected. A letter was read from Mr. Woodthorpe, town-clerk of the city, accompanying a copy of the medal struck off by Mr. Wyon to commemorate the Queen's visit to the city, and another from Colonel Pasley on the mode adopted for blowing up the brig William. A communication was read from Mr. Thornthwaite on a new apparatus for the use of divers, to enable them to fetch up articles with greater expedition, or execute with more facility any works below the surface of the water, and which had been used in the repairs of the gates at St. Katharine's Dock with great success. The principal advantage consisted in a volume of condensed air contained in a vessel, and regulated by a valve, so that the person employing it has immediate command over it. The silver medal was unanimously awarded for this invention. A description was next read of an apparatus by Mr. Bowles for raising empty casks, which consisted of a single catch introduced into the bunghole (similar to the end of a dog-chain), and the ingenuity of the invention was much admired. From Mr. Jones was exhibited a travelling platform for the purpose of descending ropes applicable to the repairs of buildings where ladders could not be applied, in descending cliffs for practical or geological purposes, or repairing wells or shafts, and for which the silver Isis medal was awarded. A report was read from the Finance Committee on the present state of the society's affairs. Amongst the extraordinary receipts of the past year was a donation of 500*l.* from Mrs. Acton, from donations 323*l.*, and a loan of 100*l.* from Mr. Solly, given without interest. The statement also exhibited the comparison of receipts and expenditure, the former of which was a little in excess.

NEW COLLEGE AT BATH.

A scheme is in progress at Bath to establish a college by shares, to be called Queen's College. It is to be something on the plan of King's College, London; and besides all the modern branches of education taught in the

University of London, is to include schools of engineering, navigation, arts, and design, and the application of science to manufactures, like the Paris Polytechnic school. The designs for the building are preparing under the direction of Mr. Manners.

ROME.

At the meeting of the Archeological Academy on the 17th May, the secretary, Visconti, read an account of an interesting and important discovery, made in a vineyard situated without the gate of Santa Maria Maggiore, near the church of SS. Peter and Marcellinus and the tomb of St. Helen. The proprietor was led, from some remains of antiquity found on the property, to examine an old neglected building, in the floor of which he discovered an entrance to a subterranean gallery, which had been filled with soil falling through apertures made in the ceiling for the admission of air. He caused the passage to be cleared, at a considerrble expense, and was amply rewarded by the discovery of a mosaic pavement, seventy-two palms in length, and five in breadth. He immediately caused the excavation to be examined by the learned secretary, who, from the close resemblance of the tombs to those in the catacombs, and principally from the emblems of the cross in the pavement, at once pronounced it to be a branch of the ancient cemetery known by the name of St. Tiburtius, SS. Peter and Marcellinus, and *inter duas lauros*. The gallery is of the same vaulted form as the other catacombs, but is higher and more spacious; along the sides, and in the transverse galleries which cross the main branch, are tombs about seven feet in length and two in height, hollowed in the wall, or in the form of altars with arches over them. The mosaic pavement is of the most elegant and varied design, and, besides the figure of a dove bearing an olive branch, ornaments, emblematic of the cross, are repeated in different form. We are inclined to believe, from an inspection of it, that the pavement was executed about the time of Constantine, and that a passage will shortly be discovered, connecting it with the well-known cemetery mentioned above.—*Dublin Review.*

MEETING OF SCIENTIFIC SOCIETIES.

Royal Institute of British Architects, Monday, 3rd and 17th instant.
Architectural Society, Tuesday, 4th instant.
Society of Arts, every Wednesday evening.

DISTRICT SURVEYORS.

At the last Middlesex Sessions, held on the 9th Nov., an election took place for two district surveyors. At the close of the voting the chairman announced that the choice of the magistrates had fallen on Mr. William Grellier and Mr. J. H. Good, jun. The former was appointed to the vacant office of district surveyor for the parish of Whitechapel; and the latter district surveyor for the parish of St. Mary, Stratford, Bow.

BELGIAN RAILWAYS.—BRUGES AND OSTEND.

BY A RECENT VISITOR.

The surface of the country is generally level, and the soil, sand resting on bog earth and light loam; on account of this flatness, no cutting exceeds four feet in depth. All roads are passed on a level: the canal is crossed twice by wooden turn bridges. A peculiar feature is, the breadth and shallowness of the ditches at the sides, from which the material has been obtained to finish the earthwork. This *prima facially* appears an unnecessary waste of land, but the necessity of it is seen, when it is considered that it is caused by the system of drainage, which would not allow excavations to be sunk deeper than a foot or two. The line is formed and packed with sand, and raised a foot or two above the level of the surrounding country. The rails, which at present are only a single line, are laid on wooden sleepers, and with very slight exceptions, appear firm. There are no side fences, and the shallowness of the ditches offers no impediment to men or cattle straying on the works. The rate of speed varies from twelve to four and twenty miles an hour, and the engines appear to work well, although the smell of the locomotives is more offensive than in England. The carriages are about ten feet broad, and being of Belgian make are rather jolting. Accidents are not unfrequent, arising from the self-sufficiency of the Belgians, who do not like to employ a sufficient number of English engineers.

A circumstance which should have an influence in comparisons between the cost of English and foreign railways occurred in this case. The Government took the land at a month's notice, without giving any idemnification for the crops, giving what price they thought proper for the land; it need not be said that there is some contrast between this and the English method of an opposition in Parliament, and a hard fought law-suit afterwards.

The system of administration seems very bad. The passenger has to pay his money at a pigeon-hole, which is closed by a glass door, the opening and shutting of which for every individual passenger at the last moment, it is needless to remark, causes considerable loss of time. The clerk having shut his window then sets to work to fill up, *sign and seal* the ticket. The applicant having done this begins to look about for his baggage, and while he sees it pitched down into the sandy mud, is directed by one of the establishment to walk into the passengers waiting-room. Seeing there no one to whom to refer, for, contrary to continental custom, the employées are not in uniform, although there are cuirassiers and infantry on sentry, he finds it necessary to look after his baggage, which after some difficulty he succeeds in getting arranged, after feeing the porters. Persons are not allowed to go from the baggage-room into the station-yard, but must return unnecessarily into the passengers-room. In the yard an officer takes the ticket or else takes it during the journey, and points out the carriage to be occupied. The first-class carriages are unnecessarily swelled in size by passages and doors, and there are no regulations against smoking, as indeed there are no other regulations visible. On arrival the officers at the station often require a ticket with the luggage, which, it is needless to say, is an unnecessary annoyance. The open carriages are indeed most miserable vehicles, without any covering at all; while the second-class carriages have badly arranged moveable leather covers. One bad feature in the administration is, that the guard or conductor receives fares on the road from passengers who have entered without a ticket; of course, in such case, there can be no efficient control against peculation.

RAILWAYS.

London and Brighton Railway.—The works on this undertaking are progressing with great rapidity through the whole extent of the line. At Clayton-hill, the shafts for the tunnel are nearly completed, and the drift-way is in a forward state; while the great work of the railroad—the embankment at Keymer—has been commenced by Mr. Thornton, who is employing a host of labourers. On the Shoreham branch the work is in a still more forward state. Nearly 100 yards of the drift-way of the tunnel, under Lashmer's-mill, has been accomplished, and men are engaged on the cuttings and embankments along the line for nearly four miles. Four bridges have been completed, and three others are in course of construction. Rails are temporarily laid in different places, for a distance of nearly two miles, and every part of the work is going on most satisfactorily.—*Brighton Gazette.*

Bolton and Preston Railway.—We are informed that nine miles of the length of this railway, commencing at Bolton, are already lined out.—*Preston Observer.*

Great Western Railway.—Cutting at Shooter's Hill.—One of the formidable obstacles in the line of the Great Western Railway, is that presented by the chalk hill on the western side of Pangbourn, which abuts on the banks of the Thames, about three-quarters of a mile in length. Excavations have been commenced at each end, and the soil, has been removed from the summit of the hill to a variety of depths; and the labourers have in this work turned up many testimonials that this hill was once the scene of a severe engagement. From six to eight feet deep in the chalk, they have found human skeletons, cannon-balls, pike-heads, and an ancient spur; and, within the last fortnight, horse-shoes so numerous as to fill a two-bushel measure. One of the men struck the pickaxe through a watch, the case of which was gold. The period of the battle, probably, was that when Charles I. advanced and retreated so often from Oxford to Reading, and from Reading to Newbury. The railway crosses the turnpike-road at Pangbourn, by a bridge of three arches; and also occasions at Purley, a diversion of the same road, to allow sufficient space for the railway between the turnpike-road and the Thames.—*Reading Mercury.*

Great Western Branch Railway from Slough to Windsor.—We have not thought it advisable till now to allude to the rumours we have lately heard respecting a branch-road from Slough to Windsor. But as an official notice of an intended application to Parliament for such branch appears in our advertising columns, and understanding that the money to bear the expense of the undertaking is ready, we venture to congratulate the inhabitants of this town, also those of Eton and Eton College, on the almost certainty of their having the advantage of a branch to the Great Western Railroad. The road, we understand, will branch from the Great Western between Slough and Salthill, will cross the Thames, and terminate close to this town. That the formation of this road will be a great benefit to the towns of Windsor and Eaton, there is no doubt, and by it also the conducts of the college will be relieved from the incessant noise of the numerous conveyances to and from Slough.—*Windsor Express.* Another meeting, between the leading men engaged in this undertaking, took place at the latter end of last week, and there is now every probability of its being carried into effect. It is intended to cross the river by the Brocas, and have the terminus in Clewer Fields, at the end of Clarence Crescent. The estimates have been carefully made; and upon what is represented to be a fair calculation, 10 per cent. on the outlay may be fully expected. —*Reading Mercury.*

The proposed Newbury and Great Western Junction Railway will be 14¾ miles in length. The estimated expense 145,000*l.*, and the gross revenue 24,500*l.* After quitting Newbury, and crossing the river Kennet about two miles below the town, it will go by Thatcham, Midgham, and Woolhampton, to near the 46th milestone, where it crosses the London and Bath road, thence proceeding nearly in a straight line, leaving Theale on the right, thence by Tidmarsh to Pangbourn, where it will join the Great Western Railway, making the entire distance from Newbury to London only 55 miles, which may be accomplished in two hours and a half. Mr. Schollar, the engineer, considers the above line to be the most eligible, and also the cheapest.—*Reading Mercury.*

Maryport and Carlisle Railway.—We understand that contracts have been completed for blocks, &c., for eight miles of this line. These eight miles lead through coal and lime, and will, it is confidently expected, be completed before September, 1839. The present traffic in coal alone would yield a gross profit of 8 per cent., and this on a reduced charge to the coal-owners, for carriage, of one-half the present cost. There is, therefore, every probability of doubling this coal traffic.

Southampton Railway.—The bridges constructed by the Southampton Railway Company across the Great Western Road at Worting, near Basingstoke, gave way last week for the second time, to the imminent danger and annoyance of travellers.—*Times.*

Midland Counties' Railway.—The following is the engineer's return of the quantity of earth-work executed, and the number of men, horses, and engines employed, on the works of the Midland Counties' Railway, from the 22nd of September to the 27th of October, 1838:—Earth-work executed, 284,160 cubic yards; number of men, 4,597; number of horses, 498; engines, 1 locomotive, 1 stationary.

The Eastern Counties' Railway.—The unbelievers of Essex are now in a state of amaze at the rapid progress of this railway. They formerly would insist that it never would reach Romford; but the line is now not only nearly completed to Romford, but the bridge over the highway from that town to Hornchurch, nearly finished, and the contract let, and rapidly proceeding with to Brook-street and Brentwood.—*Essex Standard.*

Dundee and Arbroath Railway.—Since the opening of the line, upwards of 2,800 passengers have travelled upon it, and the numbers are daily increasing. We understand that it is in contemplation to form a branch Railway to Montrose, which will still further insure the traffic, so that in every point of view this undertaking promises to be eminently successful.—*Glasgow Courier.*

Birmingham and Gloucester Railway.—It is said that the portion of the line between Cheltenham and Tewkesbury will be opened next spring. The excavations under the Gloucester road at Cheltenham have been commenced, and the cutting for the depôt is nearly completed. The designs for the latter have been for some time in preparation, and will be in the builder's hands in course of a week or two from the present time.—*Gloucester Chronicle.*

Welsh Coast-Line Railway.—George Stephenson, C.E., one of the highest authorities on railway matters, having been on a geological tour in North Wales, has examined the route of the coast-line of railway, so frequently adverted to in this journal, in contradistinction to the interior line so foolishly recommended by the Irish Railway Commissioners. The following are his sentiments respecting it, communicated to John Uniacke, Esq., Chairman of the Chester and Crewe Railway Directory:—"Dear Sir,—As I was engaged, last week, in a professional tour through Wales, in examining the geology of a portion of the country, I took the opportunity, in returning home (knowing the interest the people of Chester feel in having a communication to the Ormshead), to examine that bay, and the route from that place to Chester, as well as from Ormshead to Bangor. I find that the bay at Ormshead possesses more facilities for being made into a convenient harbour than I had any previous idea of, and that a railway may be obtained from that place to Chester almost on a dead level, and without having to encounter any heavy or difficult works; and, also, from what I saw of the country between Ormshead and Bangor, I do not think there are any difficulties to prevent a railway being made from Chester to Holyhead, if Government should hereafter be disposed to assist in carrying the communication to that point. If the line, in the first instance, is only carried as far as Conway, it would still leave that portion of the great north road from Conway to Holyhead available for the traffic between England and Ireland, and it would then remain with Government to consider whether they would still retain Holyhead on the grand station for the thorough fare between England and Ireland, or they would make the Ormshead the great packet station. It is my opinion, that no other route can be obtained, at so small a cost, to shorten the distance from England to Ireland."—*Chester Chronicle.*

Railway from Newcastle to Edinburgh.—The survey of this proposed railway will proceed with great rapidity, as it is to be carried on simultaneously in four sections, beginning from the two extremities and two intermediate points. It has already commenced at Newcastle and Berwick. A distinctive name should be contrived for this railway, which will serve the important purpose of uniting the two kingdoms. Might it not be called the Grand Union Railway?—*Scotsman.*

Birmingham Railway Station.—The great inconvenience arising from the destruction of the Denbigh Hall station is about to be remedied by the establishment of another, at the Bletchley Cross-road, about half a mile from Fenny Stratford, agreeably to the request of a large number of the gentry and farmers of that vicinity.—*Bedford Mercury.*

The Chevet Tunnel on the North Midland Railway, near Wakefield.—This stupendous undertaking, the work of many months, is at length opened, we understand, at both ends. It is about three-quarters of a mile in length, and in some places nearly thirty yards under ground. The line in the neighbourhood is fast progressing, as well as the viaduct over the Barnsley Canal, which will be a gigantic specimen of art.—*Leeds Mercury.*

Liberal Landholders.—At the Cork Railway meeting, Sir W. W. Beechey and Mr. J. D. Croker said they would not require any compensation for land of their's required for the South Western Railway. [This is somewhat contrary to the general practice of the squirearchy, and is an example much to be recommended.—Editor.]

South Eastern and Dover Railway.—We have paid our periodical visit to the works of this railway, to mark their progress. Our readers are aware that the galleries and shafts of the important tunnel at Shakspeare's Cliff are already complete, and we have now to notice that the two headways are progressing most satisfactorily. The chalk hitherto excavated is of extraordinary firmness, and fully realizes the expectations of the engineer,—that the roof of the tunnel will in no part require any extraneous support beyond the natural chalk. About four weeks hence, should the working continue as favourable as hitherto, we may congratulate our readers upon the possibility of walking through the bowels of this noted cliff. The cuttings beyond are proceeding rapidly, and still further, the second tunnel has been commenced under very favourable appearances.—*Dover Chronicle.*

London and Birmingham Railway.—Mr. Berry, who is an extensive engine manufacturer, and occupies several acres of land at Wolverton, the principal engine station on the line, has contracted with the directors for working the train of carriages the entire distance at one halfpenny per ton per mile for goods, and also at the rate of one farthing per ton per mile for passengers. The carrying department is under the management of Mr. Baxendale. The coaches recently purchased off the road are the Swallow and the Wonder, which have been carrying outside passengers at 10s. and inside at 20s. each.—The latter coach has run from Shrewsbury to London daily for several years, and admitted to have been one of the best conducted coaches on the road for its regularity.

Proposed New Railway from London to the North.—A new line of railway has just been projected, to be called the North Trunk Railway. It is proposed to commence at Islington, passing thence between Highgate and Hampstead by Finchley, Barnet, St Albans, and Bedford, between Higham Ferrers and Wellingborough, and thence to Leicester, there to join the Midland Railway This route would form a portion of a direct line from London to Edinburgh The project is sure to receive the strenuous opposition of the London and Birmingham Company, with whose traffic it would interfere very materially.—*Evening paper.*

Thames Haven Dock Railway.—The works at this Dock are progressing very fast, as far as the excavation part; and several houses have been built close to the sea wall for the occupation of the labourers. We understand this company proposes to lay four lines of rails with a six feet gauge, and to carry at extreme speed on one set, and at the most profitable rate for goods and coals on the other, this will be working out the principle of railways and locomotive power to advantage and profit. We further hear that this undertaking is fully appreciated in Belgium by all persons, from the King downwards, and that the remaining shares in the office will be taken in that country. This is discreditable to ourselves in foresight and enterprize. If the work be a good one it ought to be carried through by British capital. There cannot be a doubt that a large tide dock in such a position as that of Thames Haven, so near the entrance of the river, and within one hour's distance of the Metropolis, will command an enormous trade and traffic, the line being nearly level and straight throughout; the undertaking cannot fail to be highly beneficial to the public and profitable to the proprietary.

The Preston and Longridge Railway.—This line of railway commences, at its eastern extremity, in a field on the western part of an estate near Longridge, lately purchased by the Railway Company, situate in the township of Dilworth, and is about 200 yards from the highroad leading from many of the trading towns of the eastern parts of Lancashire and Yorkshire, to Preston; it is the same distance (about 200 yards) from the celebrated stone quarries called "Tootal Heights." The entrance to the railway is cut out of the solid rock, with which material the estate abounds. From this entrance there is a fine view of the Chipping-hills, and the diversified scenery which adorns the landscape below. The railway in this place, from the entrance, extends in a straight line about 200 yards, at the termination of which length it is continued in the form of a curve, over a viaduct of one arch, which is being erected over the tramroad called "Wilkinson's Old Lane." It then extends in a direct line for about three miles, leaving, on the south side, the village of Longridge at a distance of about 300 yards; it then passes under another bridge, built at the Four Lane-ends, in the township of Alston; to the west, or rather north-west of which is the beautiful mansion called "Gleadale House," late the residence of James Dilworth, Esq., which lies within a few hundred yards from this part of the line. In this locality the railway is about 200 yards from the public highway to Preston, so that any weight or bulk of goods of any kind, might be readily conveyed from the station-house that will, in all probability, be erected near the Alston Four Lane-ends bridge. The road, further west, proceeds towards the Plough Inn, in Grimsargh, which it passes within ten yards of the front door, having to the right the elegant residence of James Blanchard, Esq., and is carried in a straight line to the eastern part of the Parsonage-house in Grimsargh, occupied by the Rev. Mr. Grainger. To the south is the antique residence, called Red Scar, the seat of Mrs. Cross, relict of the late W. Cross, Esq., which mansion is surrounded by a profusion of beautiful scenery. In this direction is another bridge, built of wood, under which the line is constructed; it then passes the garden of Grimsargh School, and thence, without any material angle or curve, proceeds under another bridge. near to Ribbleton brow. Thence it proceeds in a regular direction to the terminus, near to St. Paul's Church, Preston.—*Preston Chronicle.*

Chester and Crewe Railway Company.—Engineer's Report on the Line.—The entire distance from Chester to the Grand Junction Railway has been for some time staked out, levelled, surveyed, and the plans of landowners prepared. The line has been divided into four contracts, the heaviest of which was let in July. The next (in point of work), the Crewe, has also been contracted for and commenced. The two remaining divisions, Bunbury and Wardle, present no difficulties of consequence, and need not be commenced upon till the ensuing spring. The following statement will explain the nature and extent of the works upon each:—Waverton Contract, let to Mr. Thomas Brassey; amount, 56,500*l.* The length of this contract is six miles and four-fifths, and it comprises 392,500 cubic yards of excavation, an aqueduct at the crossing of the Ellesmere and Chester canal, three turnpike-road bridges, three public-road bridges, and seven occupation bridges. The works were commenced upon the 8th of August, and up to the 1st of November 75,000 cubic yards were taken from the first excavation, being upwards of one-fourth. Two bridges are building; a considerable distance of the line is fenced; and the whole is proceeding in such a manner as to leave no doubt as to its being done by the 1st of February, 1840, the time specified for completion. In the beginning of a work, the difficulty of obtaining and getting materials upon the ground retards the contractor's progress, so that the quantity done in the first two months affords no criterion of what will be done in the two ensuing. The Bunbury Contract comes next in order. The length is five miles thirty chains, and include 260,000 yards of earth-work, one turnpike-road bridge, four public road bridges, and one bridge at the crossing of the Ellesmere and Chester canal. The length of the Wardle Contract is four miles six chains. It contains 204,000 yards of excavation, one turnpike, three public road bridges, and one bridge over the Middlewich branch canal. The drawings of the bridges and necessary contract plans have been prepared for these two divisions, but from their extreme lightness need not be let till the spring of next year. This will not occasion any delay in the opening of the whole line. Crewe Contract, let to Mr. Brassey; amount, 36,973*l.* This division is four miles two chains long, requires 292,000 cubic yards of earth-work, one turnpike, three public road bridges, four occupation road bridges, and one river bridge at the Weaver. The principal work is the Weaver embankment, to which the whole energies of the contractor will be directed; and though it depends in some measure upon the weather yet I have no doubt that, with proper care and attention, the whole will be completed within the period specified. The other embankment up to the Grand Junction Railway is of no moment.

Kingstown Railway.—At a meeting at Waterford, Mr. Bald, the engineer, who was present, stated that the Kingstown Railway pays six per cent. to the proprietors, but their shares are below par, from an arrangement to clear off their debt to the board of public works within a certain period.

The Accident on the Birmingham Railway.—On Friday morning, Nov. 9, about twenty minutes past three o'clock, an accident of a serious character occurred on the line of the London and Birmingham railroad, about three miles on this side of Leighton. The train started at its usual hour from Birmingham, with about fifty passengers, the Post-office letters, and luggage. On arriving about three miles and a half on this side of Leighton, where the road runs along an embankment 90 feet in height, the engine and tender got off the line in the direction of the embankment, and before it was in the power of the engineer to check its progress it had proceeded, dragging with it the greater portion of the train, right over this steep declivity, producing a concussion, which dashed the Post-office luggage-van and one of the first-class carriages to pieces, and seriously damaged the whole of the remainder. The escape of the engineers, guards, and passengers, was truly providential. The engine, after having gone down the declivity a considerable distance, became, from its immense weight, so deeply imbedded in the mould that the wheels were entirely clogged, and it fell upon its side towards the mound, which had the effect of throwing those carriages which were over the embankment in the same direction, and those remaining still on the line on their sides the reverse way. The confusion at this moment is described to have been dreadful. On the engineers, officers, and guards recovering the shock, it was found that among the passengers, with but one exception, only a few slight bruises had been sustained, and that a gentleman, who was seated alone in one of the first class carriages, was bruised about the thigh and hips by the force with which the panelling had been dashed in against him. One of the guards, named Young, was found lying at the bottom of the embankment, bruised in a most shocking manner, having been at the time of the concussion pitched, together with the foot-board and iron work of the dickey of the carriage on which he was seated, the whole depth of the declivity. He was assisted up, and placed in one of the carriages, in a weak state, but we are happy to state his injuries are not of a serious nature, as he managed to walk to his residence on the arrival of the train in town.—*Evening paper, Nov. 12.*

Explosion of a Locomotive Engine Boiler on the Liverpool and Manchester Railway.—On Monday evening, the 12th ultimo, the luggage train, which left Liverpool for Manchester, met with an accident which terminated fatally to the engineer and fireman on ascending the inclined plane at this place. The train consisted of 43 waggons, and was propelled by four engines, two in front and two behind. The rise of the road is about 1 in 90 feet, and the train, at a few minutes past eight o'clock, was seen advancing slowly up the hill at a steady pace, when, all of a sudden, the Patentee, the first engine, exploded with a noise resembling the firing of cannon, the report being heard at Prescott and other places more than a mile distant. The engine broke away from the rest of the train, and proceeded at a flying pace for 300 or 400 yards along the line. It was sadly shattered, and the tubes destroyed. A search was made for the engineer and fireman immediately on the train stopping. Both were killed, but none of the engineers or breakmen on the other engines received any injury; their escape is attributed to the tender attached to the Patentee engine having formed a resistance to the power of the exploded steam.—An inquest was held on Tuesday the 13th ultimo on the bodies of the two unfortunate sufferers. William Thomas deposed, that he was a watchman in the employment of the Manchester and Liverpool Railway Company. Last night he went on duty rather before his time, and while sitting in his box heard an explosion, and running out saw an engine flying past him. He had heard the train regularly working up the hill just before the explosion. On going out, he ran after the engine, which was the Patentee, and had run about 160 yards from the place where the explosion occurred. He found the engine detached from the tender. There were no firemen with it, and the back of the engine (the fire part) was blown away, and one of the tubes was hanging out. Witness had frequently seen the deceased "weighting" the safety-valves. He knew that the Patentee engine had been running for more than two years. Two other engines followed the train. It was dark at the time the explosion took place.—Mr Melling, engineer to the company, deposed, that he had seen the Patentee engine since the accident. The furnace end was blown out. Witness could not account for the accident. If there had been a scarcity of water, the leaden plugs would have melted, and the fire would have been put out. A burst tube would have produced the same effect. The company strongly prohibit the road engineers from "weighting" the engines, and would discharge them on its being made known that they did so. They had no right to press on the levers. Witness could not state positively whether the Patentee had a safety-valve placed out of the control of the engineers. Some of the engines have three safety valves. The Patentee had run about five years, and belonged to the Manchester end of the line. The boiler was about a quarter of an inch thick, and was calculated to bear a pressure of 50 pounds to the inch. No injury was done to the tender, except the breaking of the drag link, used to attach it to the engine. If the deceased men had the steam up at too great a pressure, and then applied pressure to the safety valves, an explosion might be the consequence. It was more dangerous to apply pressure to a boiler when the engines ascend an incline than on level ground, the steam in the latter case escaping much faster.—Richard Greenall, the road engineer to the Bank engine, which is kept in waiting at the foot of the incline to assist the trains in their ascent, deposed, that he and the other engineers last night, in consequence of their having the assistance of the Lion, a new engine, agreed to take the whole train, which consisted of 43 waggons, up the incline at once. Having four engines in the whole, he thought they had plenty of power, as the Hercules had on a previous occasion by herself taken up 17 waggons, and the Patentee 16 waggons. The two hindmost engines had scarcely felt the incline when the explosion took place. Witness had occasionally seen engineers apply weights to the engines, and thinks there is scarcely an engineer on the line who does not do so at a pinch. Warburton wished to go up the line with 33 waggons only; but the firemen agreeing with witness in the probability of getting the whole train up the incline, they started with 43.—The jury returned a verdict of "Accidental Death," with a deodand of 20s. on the engine.

FOREIGN RAILWAYS.

Railway from Odessa to Vienna.—A letter from Lemberg, in Galicia, of the 24th of September, says, that a company of rich inhabitants at Brody has proposed to the Austrian and Russian Governments, to construct, at its own expense, an iron railway from Brody and Lemberg to Vienna, and from Brody, by way of Berdztscheff, to Odessa, on condition that the Company shall have the two roads for one hundred years; after which they shall belong to the two states. It appears that the Company has already some hope that the Austrian Government will accede to the proposal, for its engineers are already commencing the line from Brody to Vienna, and its agents have conferred with several landowners in Galicia, about the purchase of the land through which the road would pass. The Emperor of Russia, it is said, has the less hesitation about authorising the construction of an iron railroad between Brody and Odessa, as he much desires to see railways become numerous in his empire, and as the Company does not ask any pecuniary aid. It is affirmed that the houses of Rothschild and Sina, of Vienna, and the wealthy Hungarian Count Czetching, intend to take shares if the plan should be realised.

Berlin.—The opening of the railway between that capital and Potsdam took place on the 29th of October.

Austria.—The number of passengers on the North Austrian Railway between April 16 and October 15, was 165,879, and the amount received 71,099 florins.

Ostend Railway.—Active measures are in contemplation to remove the station which is now outside the town, to a position nearer the harbour.

Portuguese Railways.—A railway was some time back in contemplation between Lisbon, Coimbra, and Oporto, but was necessarily abandoned on account of the distracted state of the country. The guerillas have lately committed many murders on that road, and any engineer engaged in operations on that line would be likely to make a *final* survey.

Dresden Railway.—Another six miles of the railway between Dresden and Leipsic was opened on the 3rd inst. It extends from Dahlen to Oschatz.

Bruges Railway.—The station is being improved, and a canal filled up in order to extend its limits.

Belgian Railways.—A great deal of flourish has been making by the vainglorious Belgians and their neighbours, the French, about the wonderful progress of Belgian railways; it should be borne in mind, however, that most of them are but single lines of rails.

Versailles and Meudon Railway.—A general meeting of the shareholders in this line was held on the 10th. From the report it appeared that, according to the survey and plans of M. Correard, verified by the Council of the Ponts et Chaussees, and approved by the government as the basis of the grant of the line, that the total expenses of the undertaking was estimated at less than 4,000,000 francs. It has since proved that the road, as far only as it hast hitherto been carried, has nearly absorbed 8,000,000 francs, and must definitively cost, according to the best calculations, 15,000,000 francs. [We recommend this to the attention of our House of Commons.]

Versailles Railway.—It is said the two companies have agreed to unite, so that there will be only one entrance for both lines at Versailles, the point of junction being made in the valley somewhere beyond Sevres, and the starting point of the Meudon line may then perhaps serve for that of the line intended to be directed on the south-west of France, by Chartres, Tours, &c.—*Galignani.*

ENGINEERING WORKS.

Montrose Bridge.—We understand that a communication has been received from the Exchequer Loan Commissioners (who are now *de facto* the Bridge Commissioners), intimating their intention to repair the structure forthwith, and that Mr. Rendel, civil engineer, is with that view on his way hither. The question, what is to be done to secure a more stable and permanent medium of communication at this ferry, remains to be decided by the Treasury. The bridge has been inspected since our last by Mr. Rendel, Government engineer, who, in a report delivered to a meeting of the commissioners, confirmed the statement we formerly gave respecting the extent of the casualty. The main chains, he reported, remain uninjured; and although the roadway will require to be thoroughly reconstructed, the bridge may be temporarily repaired, and rendered passable for both foot passengers and carriages in about a month, at an expense of 450*l.* The commissioners resolved to proceed with this repair in the beginning of next week, and to memorialise the Treasury for authority to effect the reconstruction of the roadway on an improved principle, recommended by Mr. Rendel, next season.—*Montrose Review.*

Lighthouse on the Barlings.—The Director of the Customs at Lisbon, has, issued a notification for tenders to be sent in for the erection of a lighthouse on the Barlings, which has been so much wanted on those dangerous impediments to the entrance of the Tagus, and so long talked of.—*Diario do Governo.*

Bristol.—The clearing out of stones and trees which impeded the navigation of the Severn, has just been finished. The works on the Clifton Suspension Bridge are in full vigour, but it will take some time before the towering piers are completed.

Floating Steam Bridges.—In the transactions of the Institution of Civil Engineers, reviewed in our number of this month, is an account of the floating steam bridge over the Hamoaze, on which we may remark, that, in addition to this machine, another is in active operation at Southampton, and one is now in progress to ply in Portsmouth harbour. They are found to be profitable undertakings.

Mr. Beaumont, late M.P. for Northumberland, has subscribed 10,000*l* towards the building of a new bridge across the Tyne, near Hexham. It is said he contemplates likewise the erection of a splendid mansion on his own estate in that neighbourhood.—*Standard.*

Temporary Suspension Bridges.—A correspondent suggests that rope bridges might be used to a much greater extent for communication in poor districts, as in the mountains of Ireland. In Sir A. L. Hay's recent work on the Peninsular war, among the descriptions of several engineering operations is one of the rapid construction of a rope bridge, over which the whole army, with cavalry, artillery, and baggage, passed with safety, while its cost was comparatively trifling, and the materials furnished from the campaign stores.

STEAM NAVIGATION.

Government Steamers.—Pembroke Dockyard is very active now in the construction of steamers, several being now on the stocks, and one launched nearly every month.

Coppering before Launching.—The Merlin steam-boat was launched at Pembroke Dock-yard, on the 18th of last month. She is intended to carry the mails between Liverpool and Kingston Harbour. She was wholly coppered on the stocks, by which government saved the expense of taking her into dock. To save the copper from being injured by the cradles, they were fastened by ropes running underneath the keel, and by abutment pieces extending to parts above the counter.—*United Service Magazine.*

Paddlewheels.—The Megera has returned from the Mediterranean on account of the defective state of her paddlewheels, which are constructed on a principle, which in itself perhaps is good, but which is said to be liable to strong objections in practice, in consequence of the friction resulting from the mode of working. Some of the bolts upon which the joints of the paddles turn, after being in use about six months, are worn down from three inches to 1 inch in diameter.—*United Service Magazine.*

French Steam Navigation.—A steam-boat is going to ply on the Isere, from its junction with the Rhone, to Grenoble. The new communications which will thus be opened for goods coming from Savoy, Piedmont and Italy will be of the greatest importance.—*French paper.*

Mediterranean Steam Navigation.—The number of travellers passing through Marseilles for Italy and the Levant is unprecedented. The last packet, the Mentor, conveyed 117 passengers, many of whom were obliged to sleep in their carriages or on the cabin benches.

Indian Steam Navigation.—Two out of the five stations intended to be erected between Suez and Cairo are already in activity, and greatly facilitate the intercoure between those cities.

American Steam Navigation.—A steam-boat to communicate between New York and Bordeaux, has lately been launched at this latter port, which is one of the principal in France for its river steam navigation.—*Memorial Bordelais.*

Black Sea Navigation.—The government has lately purchased, in England, two iron steam-boats, the Inkermann and the Newka. The first is intended to ply between Constantinople and Odessa. It arrived at Odessa the 9th ult., having performed the voyage from London in 39 days.—*Hamburgh paper.*

French Steam Vessels.—The French government have advertised for 21,000 tons of coals, for the service of the Medeteranean packets.

North American Steam Navigation.—The government have advertised for tenders to convey the mails by steam vessels, of at least 300 horse power, from England to Halifax, and from England to Halifax and New York.

NEW CHURCHES.

New Church at Rotherhithe.—On Tuesday, Nov. 6th, the ceremony of the consecration of Holy Trinity Church, in the parish of St. Mary, Rotherhithe, was performed with the usual ceremonies by the Bishop of Winchester. The new church is a spacious edifice, in the pointed Gothic style, capable of accommodating 1,000 persons, situate in the lower part of Rotherhithe, near the Commercial-dock, about a mile and a half from the old parish church, and in the midst of a very populous district, where the want of a church has been long and deeply felt by the inhabitants. A grant of 2,000*l.* from the Metropolis Churches Fund, 1,000*l.* from her Majesty's Commissioners for Building and Enlarging Churches and Chapels, and 500*l.* from the Incorporated Society for Building Churches, has been given towards the erection, and besides 100*l.* from the master and fellows of Clare Hall, 50*l.* from the rectors, 50*l.* from Mr. W. Bennett, the shipowner, the same sum from Major-General Sir W. Gomm, and 25*l.* given by Mr. W. Evans, M. P., about 360*l.* has been subscribed by the inhabitants. The total expense of erection and the endowment for the minister is 5,770*l.*, of which 4,060*l.* has been collected, leaving a deficiency of 1,709*l.* Attached to the church are two spacious infant schools, one for boys and the other for girls, which have been recently erected by the voluntary subscriptions of the parishioners.

Westmoreland.—A new church, to be named "St. George," has just been commenced at Kendal, on the north-east side of the river Kent, between Stramongate-bridge and Kent-terrace. The design is of the early Gothic style; the principal front contains, in the centre, a large triple lancet-arched window, and the principal entrance under; at the angles are large octagonal spiral turrets; and on the east side are two porches, which, with the principal entrance, communicate with the vestibule. The interior arrangements have been planned with every regard to comfort and convenience. The vestibule occupies the whole width of the west end; the centre of the church, and surrounding the pulpit and altar, will be occupied with free seats, and a gallery will extend along the two sides and the west end, approached by stone staircases in the turrets. The main timbers of the roof will be exposed to view, and arranged so as to give them an ornamental appearance; the ceiling will be three-sided, and ornamented with diagonal mouldings in stucco, and enriched cornices. The nave of the church will be 83 feet long, 50 feet wide, and 40 feet high; the altar recess is 24 feet by 10 feet. The cost of the church alone (which is to be built of beautiful white limestone) will be about 3,500*l.*; and the enclosure (a handsome Gothic railing), and the furniture of the grounds, with incidental expenses, will amount to about 700*l.*, making the total cost 4,200*l.*, the funds of which are raised thus:—Commissioners for Building New Churches, 1,000*l.*; Incorporated Society, 400*l.*; the remainder by voluntary subscriptions. The Lords of the Manor, viz. the Earl of Lonsdale and the Honourable Fulk Greville Howard, presented the ground upon which it is to stand, in addition to other subscriptions by them. With this edifice Kendal will have three churches, standing at the three extreme angles of the town, which will together afford accommodation for about 3,500. Population about 13,000. Mr. Webster, of Kendal, is the architect.

Church Consecrations.—The Lord Bishop of Ripon during last month consecrated three new churches in the archdeaconry of Craven, Lothersdale, Stoneyhurst-green, and Settle. Lothersdale church is the first church which has been built and consecrated in Craven for the last 300 years. We cannot omit to notice the munificent gift of 1,000*l.* from the Rev. Walter Levitt, B.D., the vicar of Carlton, towards the endowment of the church. The new church at Stoneyhurst, or Hurst-green, has been built under peculiarly interesting circumstances; and the situation is romantic in the extreme. The consecration of the new church at Settle was attended by the most influential families in the neighbourhood. The peculiar feature in this consecration is, that amongst the largest contributors to the new church are several members of the Society of Friends—a circumstance highly creditable to them, and valuable to the friends of the church.—*Times*, Nov. 10.

PUBLIC BUILDINGS AND IMPROVEMENTS.

Metropolitan Improvements.—We are glad to see several notices for application to Parliament for forming new streets in different parts of London. In the city, an application will be made to form a new street from Moorgate to the New Post-office, parallel with Cheapside, and to widen Bartholomew-lane. Another important improvement is for forming a new street and viaduct nearly parallel with Holborn and Skinner-street, to commence the corner of Fetter-lane, and pass across Bartlett's-buildings, Thavies-inn, the back of St. Andrew's Church, over Shoe-lane and Farringdon-street, and terminating at the corner of the Old Bailey and Skinner-street, immediately opposite Newgate-street; the street will be nearly a level, and will avoid interfering in any way with the houses, either in Holborn or Skinner-street. At the west end an application will be made for forming a street from the Houses of Parliament to the New Palace, and for forming squares, and other improvements, on the south side of St. James's Park. The Crown have also given notice for taking down all the houses forming a square; Downing-street on the north, Lower Crown-street on the south, King-street on the west, and Duke-street and St. James's Park on the east, for the purpose of forming a new street from King-street to Duke-street, and building public offices. Another application will be made for forming a new street from Carey-street to the Strand, and also for forming a communication between Pall Mall and King-street, St. James's-square.

Batteries.—Colonel Ward, of the Royal Engineers, and other surveyors, are now visiting the ports of Cumberland, and reconnoitring their capabilities of defence, with a view to erect batteries, and make other preparations of defence and precaution, in the event of a foreign war.—*Whitehaven Herald.*

A whole-length statue of the late Viscount Downe, executed by Chantrey, has just been erected in Snaith Church, Yorkshire, to the memory of that highly respected nobleman.

The Gordon Monument.—Elgin.—The committee appointed for erecting a monument to the memory of the Duke of Gordon, on the Ladyhill, met in Elgin on Tuesday last, and agreed with Messrs. Brander and Shand, masons, for executing the work at the sum of 1,240*l.* The work will be immediately commenced, and the structure, while it will perpetuate the memory of the noble duke, will also be a great ornament to the town.—*Elgin Courant.*

The Monument of Nollekens.—A monument to the memory of this celebrated sculptor has just been erected in Paddington church, in which edifice the mortal remains of the deceased have been deposited some years. Why the monument was not put up before, it would be difficult to conjecture; the veteran artist left plenty of money behind him to persons who might have defrayed the expenses of such a testimonial, and sufficient reputation to make it a matter of surprise that anything niggardly or dilatory should have retarded its erection. Be this as it may, the monument is at length put up. It is the work of Mr. Behnes, and it is a work that will add to his reputation, and show, that however excellent he may be as a carver of busts, he can do other and more difficult things equally well. The monument is of white marble; on it is represented a sarcophagus, on the front of which is carved, in very bold relief, the figure of Nollekens, employed upon one of his principal works—the monument of a lady who died in child-birth. The group is very fine; the attitudes of the figures graceful and easy, and the body of the dead child relaxed in the moment of dissolution but stiffening into the rigidity of death. The likeness of Nollekens is a correct one; it has the character and mannerism of the old man, and portrays his peculiar look with great fidelity of imitation. The monument should have been erected years ago; it is, however, consolatory that it is at length erected, and that the execution of it has been intrusted to an artist capable of doing justice to the subject.

FOREIGN INTELLIGENCE.

Paris.—The pediment over the portico of the Chamber of Deputies is about to be cleared of the figures that now occupy it, and will be filled with a new alto-relievo by M. Carlot. M. Pradier is charged with the execution of the basso-relievo on the wall to the left hand of the portico, and M. Rudde with those to the right. The basso-relievo still wanting in the body of the chamber is to be supplied by the chisel of M. Ramey, and M. Guérard is engaged to execute the groups which are to be placed on the pedestals in the Cour d'Honneur.—*Paris paper.*

Conservatoire des Arts et Metiers.—A commission of men of science and manufacturers has been appointed to draw up a report for the re-organization of this valuable institution.—*Memorial Bordelais.*

Palais de Justice.—The Council-General of the Seine, or Board of County Magistrates, has voted a sum of 7,500,000 francs (300,000*l.*), to be applied to the restoration and enlargement of the Palais de Justice.—*Galignani's Messenger.*

French Waterworks.—The Municipal Council of Versailles has voted a sum of 400,000 francs (16,000*l.*), and applied to government for a grant of 1,500,000 francs (60,000*l.*), for the purpose of enabling the town to be supplied with an additional quantity of water, by taking advantage of the works recently finished at Bezons, a little above Marly.—*Galignani's Messenger.*

Rouen.—A society has opened a subscription for the purpose of making researches throughout the department of the Seine-Inferieure for coal, it being expected that several extensive formations of anthracite, sufficient to repay the expense of working, may be met with.

Belgian Prices of Footpaths of Asphalte de Lobsan.—For any quantity under 25 square metres, or 29 square yards, plain, 6f. 50c. (5s. 2d.); lozenged, 6f. 75c. (5s. 4d.). For any other quantity per 25 square metres, plain, 6f. (4s. 9d.); lozenged, 6f. 50c. (5s. 2d.).

Belgium.—The city of Courtrai has this year been lighted with gas, and it is also in contemplation to extend the same system of illumination to Bruges.

Ostend Mails.—There is some talk of the mails for England being sent by Belgian steam-boats to Ramsgate, which used to be the English packet station previous to its removal to Dover.

The Dutch papers state that a commission appointed by the King of Holland has submitted to his Majesty a plan for the establishment of a great commercial entrepot and dock at Rotterdam, chiefly for the benefit of the navigation of the Rhine. This important plan is said to be connected with the making of a branch of the iron railroad to Arnheim, which is to begin at the entrepot and join at Utrecht the Amsterdam railroad.

Hamburgh.—The new English church, which is a handsome structure, was opened for divine service on the 11th instant.

Educational Despotism in Gerome.—The Ministers of Public Instruction have addressed a circular to the Rectors of the University, recommending them to compel the heads of private establishments, and schools of secondary instruction, to send pupils above the age of ten years, to the classes of the colleges, conformable to the University regulation.

Neapolitan Mines.—Mr. Beck, an Englishman, has obtained from the government the exclusive privilege of extracting all mineral substances, as coal, bitumen, alum, &c., throughout the kingdoms of Naples and Sicily. The company established to work these mines is possessed of considerable capital. The royal patent is dated the 24th of September.—*Malta Gazette.*

Venice.—During the presence of the Emperor of Austria at Venice, he laid, with great ceremony, the first stone of the breakwater about to be constructed at the port of Malamoco.—*La Presser.*

Prussia.—Prince Albert has just laid the foundations of a magnificent palace at Kamentz, in Silesia.

Swedish Iron.—By a recent decree, the King of Sweden has freed bar iron from monopoly, and proprietors of forests, or mines, are allowed to erect works on their own premises. The manufacture of iron in Sweden, however, is still greatly embarrassed by the trammels of law.

Russian Coal Mines.—A person sent by Count Worowsow has discovered a very rich stratum of coals, adapted to the use of steam-boats, in the south of Russia, in the mountain of Soukhia Yalta, 80 wersts from Marienpol and 180 from Alexandrousk, and accessible from the Dnieper.—*Journal de St. Petersburgh.*

Danube Navigation.—Since the occupation of the mouth of the river by the Russians, their efforts to destroy the trade of the Moldavian ports of Braila and Galatz, have been unceasing. Having been defeated in these attempts, they have now commenced one of more promise, and have neglected to clear off the accumulations of sand from the Black Sea which the Turks used to remove, and which now threaten to destroy the navigation.

Turkish Canal.—The canal to join the Danube (on the line from Rosova to Chiutenza) is to be restored by the Danube Steam Navigation Company. A recent firman authorizes them to repair this old Roman work.

Egyptian Canal.—A company has been formed at Alexandria for the navigation of the Mahmoudie Canal, executed by the Pasha. The object of the company is to facilitate the communication from Alexandria to Atfe, and an active and regular service of boats towed by horses was to be established.—*Semaphore.*

Alexandria.—Great improvements in building are taking place in the Place Manschee, due principally to the example of Ibrahim Pasha. Several Europeans have erected commodious houses on the same site, and those edifices altogether formed an oblong square 1,290 French feet by 200. There are at Alexandria two theatres, one French and the other Italian, and a Philharmonic Society. Another Italian theatre, planned by an Italian architect, and capable of containing 600 persons, is erecting.—*Semaphore.*

Algiers.—The French have added a new portico to the Grand Mosque.

Algerine Antiquities.—The Roman remains of Russicada (now Stora) are stated to be well preserved, and in particular an amphitheatre, two temples, and a magnificent cistern or fountain.—*Galignani's Messenger.*

Algerine Harbour.—A naval engineer has been sent to the new French conquest of Stora, to devise means of securing the vessels in the harbour against all danger.

Gas Companies in America.—The New York Gas Light Company has declared a semi-annual dividend of 5 per Cent.—*New York Courier and Enquirer.*

New York Canals.—The tolls received on the New York State Canals from the opening of canal navigation to the 30th of September, were—

	Dollars.
In 1837	833,404
In 1838	1,083,509
Increase of 1838	250,104

or a fraction over 30 per cent.

MISCELLANEA.

Parallax of the Fixed Stars.—This important and valuable problem, which has for so many centuries been an object of inquiry amongst astronomers, has, it appears, by letters received in this country, been solved by Professor Bessell, of Königsberg. His observations were made on the double star, No. 61, in the constellation Cygnus, whose distance he has ascertained to be 660,000 times the radius of the earth's orbit, or 62 trillions and 700 billions miles in round numbers. The details of this discovery will be communicated at an early meeting of the Royal Astronomical Society.

Dublin School of Mining.—We believe it is not generally known that the Royal Dublin Society have a school of mining, of which Mr. Richard Griffiths is one of the professors, and at which regular courses are given.

Coal Mines.—A valuable mine of fine sea coal has been discovered at Glen Crossack, in the Isle of Man, which is now being worked by the Isle of Man Company, with the prospect of a rich harvest.—*Mona Herald.*

Robbery from the Cornerstone.—Two men, named Western and Pearse, were brought before the magistrate, charged with undermining a new house building in Exeter, and nearly destroying it. Western is a foreman, and Pearse a stonemason. There had been several pieces of money deposited in the cornerstone of the house, and the prisoners had dug under the foundation, taken out the stone, and, robbing it of the money, had replaced it, greatly to the injury of the building. The magistrates fined them, under the Wilful Damage Act, 8*l.* and costs, or three months' imprisonment.—*Exeter Post.*

Liverpool promises to give the gentlemen of the long robe full employment during the ensuing session of Parliament. First and foremost, the town-clerk is going to Parliament for bills to amend certain other bills; then the vestry-clerk goes for a bill to rate the dock estate to the relief of the poor; next, the law-clerk to the highway board applies for a bill to extend the powers of another bill relative to the trust; and, to crown the whole, the dock solicitor, in a notice as long as the sea-wall itself, announces that he wants a bill to empower the trustees to erect warehouses on the dock-quays, &c. So that some 20,000*l.* will, in all probability, change hands in applying for and opposing these various bills. Heaven protect the pockets of the people, therefore, say we, for assuredly they will be assailed by many and dexterous hands. The Lancashire and Cheshire squires, taking advantage of the application of the dock solicitor to Parliament for a new bill, announce, through their solicitor, Mr. Wagstaff, of Warrington, that they go for a bill to vest the conservancy of the river Mersey in the hands of commissioners, and to enable the said commissioners to defray the cost of making embankments, &c., out of the rates levied by the corporation and the dock trustees respectively. Well done, Messrs. the Squires; a busy and expensive session you promise to make the next.—*Liverpool Albion.*

Fire-proof Composition.—A trial of this composition took place lately at Manchester, but in one or two places the cement fell off, and the fire took effect on the parts uncovered.—*Manchester Guardian.*

Sir James Anderson's steam-coach is finished, and will start from Buttevant for this city in a fortnight, travelling at fifteen miles an hour.—*Limerick Chronicle.*

Mining and Miners.—The total ignorance of almost everything relating to the sciences of Geology and Mineralogy, and, above all, of Chemistry, in the conductors of mines and their agents, is not only matter of regret, but, it can hardly be doubted, is also the cause of much loss to the adventurers in mines, to the lords of the soil, and to the buyers of the ore. If a spirit of inquiry had existed, which some knowledge of these sciences could not have failed to produce, much cobalt would not have been thrown away upon the heaps of Dolcoath, and some other mines; nor would bismuth in Wheal Sparnon have been mistaken for cobalt; nor would the roads have been mended with copper ore; nor would the ponderous ore which contained silver, in Herland mine, have been left to the chance that discovered its value; nor would many miners, in opposition to the known principles and properties of mineral bodies, believe, even to this day, in the regeneration of metals. While in France and Germany there are national institutions for the education of those intended to conduct the working of mines in the three important branches of science above alluded to, and which are so intimately connected with their occupation, in this country all is left to accident; and the rich gifts which nature has bestowed upon us, are consequently often neglected, or lavishly thrown away. *Geological Transactions.*

Avery's Rotatory Steam-Engine.—This is an American invention, lately introduced into this country. Mr. Hugo Reid, in his Treatise on the Steam-Engine, observes that, "If found available, it will be extremely valuable, from the cheapness of its first construction and the simplicity of its operation." It now appears, from the *Scotsman*, that several have been erected, and are much approved of. Mr. Hepburn, a farmer of East Lothian, has had one applied to his threshing machine, which answers admirably. Several are now constructing for various purposes, and Mr. Ruthven, an engineer, has made the following report of one set up on his own premises:—"It is working two planing machines, two boring apparatus, six turning lathes (one of them boring cast steel bores, four and five feet long, the aperture being about one inch in diameter), two grindstones, a pump drawing water twenty feet from the surface, and forcing it into the boiler, and a tilt hammer, giving upwards of forty strokes per minute—and this is done at an expense of from 12s. to 15s. per week for coals, working sometimes eighteen hours out of twenty-four without stopping.

Carvings in Wood.—Two very curious and very elaborate carvings in walnut-tree wood, of the alto-relief class, have just been brought to this country. They were formerly in the possession of the Emperor Napoleon, whose eagerness to possess the rarest gems of art was much more than commensurate with his respect for *meum* and *tuum*. These carvings are each about five or six feet in length, and about three or four in height or width. One of them represents the victory Constantine over Maxentius. The design is from Julio Romano, and is known to artists. It contains upwards of 200 figures of combatants, horse and foot, mingled and grouped with great pictorial effect, and carved with extraordinary boldness and accuracy; the finish of the armour costume, and minute details, is very delicate. The second tablet is after a design by Rubens; some of the figures after Leonardo da Vinci. The subject is the scriptural battle in which Joshua commanded the sun to stand still. This carving is in higher relief than its companion; it contains fewer figures, and most of them are equestrian. It is full of spirit, and cut with great freedom of hand. These carvings, which certainly surpass anything that is generally to be seen in this country, are by an Italian artist, Simon Cognoulli, and bear date 1761. Upon the downfall of Napoleon they were returned to their original locality, the castle of Salms. They are now in the possession of Mr. Farrar, of Wardour-street, who has just purchased them from the representative of the family to which they belonged, in consequence of the demise of the head of it, and the necessity of a *distributio bonorum* by the laws of Germany.

Enormous Chimney.—The new chimney recently erected at Mr. Muspratt's chemical works has recently been put into operation. It is stated to be the highest chimney in England, measuring no less than 132 yards 1 foot 6 inches from the base to the summit.—*Liverpool Albion.* [This is nearly as high as the great Pyramid.]

Ingenious Invention.—Mr. James Duncan, watchmaker, Glenluce, has lately constructed a small steam-engine on the high pressure principle, the novelty of which consists in the steam acting twice in the cylinder before it escapes into the atmosphere, by which there is a saving of half the fuel and half the water which a common engine of the same power would require.—*Edinburgh Courant.*

Geology.—Mr. Buckland is now making a tour of investigations in Switzerland, and was by the last advices at Chaux de Fond, in Neufchatel.

Geology.—The Archbishop of Bordeaux, has ordered geology and the physical sciences to be taught in all the seminaries of his diocese, and commenced the formation of collections of these objects. [What a contrast this is to the conduct of the *Times*, the leading journal of the age, in denouncing geologists as Atheists!]

March of Steam.—As the year 1838 will most assuredly form a remarkable epoch in the history of steam navigation, it may not be thought uninteresting to trace the advances it has made since the year 1814, when one steam-boat, of 9 tons burden, floated in solitude on the British waters.

The following authentic account of the number and tonnage of steam vessels belonging to the British empire (including the plantations), from 1814 to 1836 inclusive, has been politely supplied to us by the Secretary of the Liverpool Statistical Society:—

Year.	Vessels.	Tonnage.	Year.	Vessels.	Tonnage
1814	2	456	1826	248	28,958
1815	10	1,633	1827	275	32,490
1816	15	2,612	1828	293	32,032
1817	19	3,950	1829	304	32,283
1818	27	6,441	1830	315	33,444
1819	32	6,657	1831	347	37,445
1820	43	7,243	1832	380	41,669
1821	69	10,534	1833	415	45,017
1822	69	13,125	1834	462	50,736
1823	82	14,153	1835	538	60,520
1824	82	15,739	1836	600	67,969
1825	81	20,287			

—*Liverpool Mail.*

LIST OF ENGLISH PATENTS GRANTED BETWEEN THE 31st OCTOBER, AND THE 26th NOVEMBER, 1838.

Paul Chappe, of Manchester, Spinner, for "Certain Improvements in the Means of Consuming Smoke, and thereby Economising Fuel and Heat in Steam Engine and other Furnaces and Fire Places."—31st October; 6 months.

Luke Hebert, of Staple's Inn, Civil Engineer, for "Certain Apparatus and Processes for Storing, Cleaning, and Preserving Grains."—3rd November; 6 months.

Abraham Bury, Esq., of Manchester, for "Certain Improvements in the Mode of Printing, Colouring, or Dyeing Cotton and other Fabrics, and in the Mode of producing Certain Acid or Acids applicable to those or other Purposes."—3rd November; 6 months.

Jacob Tilton Slade, of Carburton Street, Gentleman, for "Certain Improvements in Pumps for Liquids or Aeriform Fluids."—3rd November; 6 months.

Joseph Fraser, of Halifax, Railway Contractor, for "Certain Improvements in the Apparatus or Machinery to be employed as Centerings or Supporters in the Construction of Bridges and Arches, and in Tunnels or other Mining Operations."—3rd November; 6 months.

Horace Corey, of Narrow Street, Limehouse, Bachelor of Medicine, for "Improvements in the Manufacture of White Lead."—3rd November; 6 months.

Charles Callis Baron Western, of Rivenhall, Essex, for "An Improvement in Drills for the Purpose of Drilling Corn, Grain, Seeds, Pulse and Manure."—3rd November; 6 months.

William Morgan, of New Cross, Surrey, Gentleman, for "Improvements in the Generation of Steam."—3rd November; 6 months.

Adolphus Henri Erneste Ragon, of Great Portland Street, Professor of Literature, for "Improvements in the Manufacture of Glass, and in the Production of other Vitrified Matters applicable to Architectural Purposes."—3rd November; 6 months.

Edward Cooper, of Piccadilly, for "Improvements in the Manufacture of Paper. Communicated by a Foreigner residing abroad."—3rd November; 6 months.

Charles Flude, of Liverpool, Chemist, for "Improvements in Applying Heat for Generating Steam, and for General Manufacturing and other useful purposes where Heat is required, and also for an Improved Mode of supplying Steam Boilers with Hot Water, the said Improvements having for their object the Economy of Steam."—3rd November; 6 months.

Jerome Deville, of Crutched Friars, Coach Builder, for "Improvements in Rail Roads, and in Carriages used thereon."—3rd November; 6 months.

James Berington, of Charles Place, Shoreditch, Veterinary Surgeon of Cavalry, for "Improvements in Knapsacks."—3rd November; 6 months.

Robert Beart, of Godmanchester, Miller, for "Improvements in Apparatus for Filtering Liquids."—3rd November; 6 months.

William Henry James, late of Birmingham, but now of Lambeth, in the County of Surry, Civil Engineer, for "Improvements in Apparatus for Heating, Generating, and Cooling Fluids, and in Engines to be actuated by such Fluids, Parts of which Improvements are applicable to the Raising and Forcing Fluids."—6th November; 6 months.

Luke Herbert, of Bristol Road, Birmingham, Civil Engineer, for "A New or Improved Process for Embalming the Dead, and for Preserving Corpses for Anatomical Purposes. Communicated by a Foreigner residing abroad."—6th November; 6 months.

Moses Poole, of Lincoln's Inn, Gentleman, for "Improvements in Apparatus or Machinery for obtaining Rotatory Motion. Communicated by a Foreigner residing abroad."—8th November; 6 months.

John Jockes, of Shropshire, Gentleman, for "Improvements in Steam Engine Boilers, and in Apparatus for Feeding Furnaces and Fire Places, and for the more effectual Combustion of the Smoke and Gases arising therefrom."—8th November; 6 months.

Bryan T. Anson Bromwich, of Clifton-on-Tine, Gentleman, for "Improvements in Machinery to be worked by the application of the Expansive Force of Air, or other Elastic Fluids to obtain Motive Power."—8th November; 6 months.

John Small, of Old Jewry, Merchant, for "Improvement in Filtering Liquids. Communicated by a Foreigner residing abroad."—8th November; 6 months.

Henry Huntley Mohun, of the Regent's Park, M.D., for "Improvements in the Composition and Manufacture of Fuel, and in Furnaces for the Consumption of such and other kinds of Fuel."—8th November; 6 months.

Thomas Mayos Woodyatt, of Cookly, Screw Manufacturer; and Samuel Harrison, of Birmingham, for "Improvements in the Manufacture of Wood Screws."—8th November; 2 months.

John Browne, of Castle Street, Oxford Street, Esq., for "Improvements in Paving Roads and Streets."—8th November; 6 months.

Felix Macartan, of St. Martin's Lane, for "Improvement in Treating the Waste Matter resulting from the Washing of Wool, and Woollen Fabrics."—8th November; 6 months.

William Watson, Jun., of Leeds, Manufacturing Chemist, for "Certain Improvements in the Manufacture of Materials used in the Dyeing of Blue and other Colours."—8th November; 6 months.

John Winrow, of Gunthorpe, Nottingham, Mechanic, for "Certain Improved Means of, and Apparatus for, Destroying Weeds and Insects on Land."—8th November; 6 months.

James Drew, of Manchester, Civil Engineer, for "Certain Improvements in the Means of Consuming Smoke, and Economising Fuel, in Steam-Engine or other Furnaces or Fire Places."—8th November; 6 months.

Hugh Ford Bacon, of Fen Drayton, Clerk, for "An Improvement or Improvements in the Construction of the Glass Holders and Glass Chimneys of Gas Burners."—10th November; 6 months.

John Holmes, of St. John's Terrace, Worcester, Engineer, for "Improvements in Forming Moulds for Casting in Metal, Studs, Buttons, Nails, Tacks, and a variety of other articles."—13th November; 6 months.

George Smith, of the Navy Club House, Bond-street, or Captain in the Royal Navy, for "Certain Improvements in Vessels to be propelled by Steam or other Power, and in the Construction and Arrangement of the Machinery for propelling."—13th November; 6 months.

Anne Bird Byerley, of 147, Strand, Widow, and James Collier, of the same place, Civil Engineer, for "Certain Improvements in obtaining Motive Power."—13th November; 6 months.

Sally Thompson, of North-place, Gray's Inn-road, for "Certain Additions to Locks and Fastenings for Doors of Buildings, and for Cabinets, Drawers, Chests, and other Receptacles, for the purpose of affording greater Security against Intrusion by means of keys improperly obtained."—13th November; 6 months.

Edward Samuell, of Liverpool, Merchant, for "Improvements in the Manufacture of Soda."—13 November; 6 months.

Joseph Eden Macdowall, of No 257, High Street, Borough, Watch Maker, for "An Improvement in the Manufacture of Escapements for Chronometers, Clocks, and Watches."—15th November; 6 months.

Thomas Trench Berney, of Morton Hall, Norfolk, Esquire, for "Certain Improvements in Cartridges."—15th November; 6 months.

William Thorp and Thomas Meakin, of Manchester, Silk Manufacturers, for "Certain Improvements in Looms for Weaving, and also a new Description of Fabric to be produced or woven therein."—20th November; 6 months.

William Watson, Jun., of Leeds, Manufacturing Chemist, for "Certain Improvements in the Manufacture of Liquid Ammonia, by which the same may be made applicable to the purposes of Dyeing, Scouring, and other manufacturing processes."—20th November; 6 months.

Harrison Grey Dyar, of Mortimer Street, Cavendish Square, Gentleman, for "Improvements in the Manufacturing of Zinc."—20th November; 6 months.

John Wilson, of Liverpool, Lecturer on Chemistry, for "Certain Improvements in the process of Manufacturing Alkali from Common Salt."—22nd November; 6 months.

Fanquet Delarne, Jun., late of Deville, near Rouen, in the Kingdom of France, but now of Manchester, Calico Printer, for "Certain Improvements in the Process of Printing, or otherwise applying and fixing the colouring matter of Madder upon Cotton, Silk, Linen, and other fabrics without Dyeing, and producing by these means Permanent Colours."—22nd November; 6 months.

John George Bodmer, of Manchester, Engineer, for "Certain Improvements in Machinery-tools, or Apparatus for Cutting, Planing, Turning, Drilling, and Rolling Metals and other Substances."—22nd November; 6 months.

Abraham Cohen, of Islington, Esquire, for "Certain Improvements in the Construction of Railway Carriages, and in the Modes of Connecting and Retarding Railway Trains."—26th November; 6 months.

NOTICES TO CORRESPONDENTS.

In consequence of the present number containing the Index and Contents, we have not had time to examine several communications and books, which we have been obliged to postpone until next month.

We will endeavour to devote, in our future numbers, a larger space for our Architectural friends. We have received several suggestions for increasing the size of the Journal for that purpose; but this we are not disposed to do, as it will entail an additional sixpence on the work; but if we find that we cannot compress all our communications in the present sized number, we will publish quarterly an additional sixteen pages, and charge the sixpence extra.

Subscribers are particularly requested to complete their sets of numbers for the first volume immediately.

We shall feel obliged to the profession if they will forward us accounts of works in progress, new inventions and discoveries; and particularly if our country subscribers will send us any newspaper containing any matter relative to the objects of our Journal.

Books for review must be sent early in the month; communications prior to the 20th; and advertisements before the 26th instant.
